Use thermodynamics to decide if the reaction is product- or reactant-favored at equilibrium at 298 K. Will the reaction be more or less product-favored at a high temperature?

92. Metals generally react with hydrogen halides to give the metal halide and hydrogen. Determine whether this is true for silver by calculating $\Delta_r G°$ for the reaction with each of the hydrogen halides.

$$Ag(s) + HX(g) \rightarrow AgX(s) + \tfrac{1}{2}\ H_2(g)$$

The required free energies of formation are:

HX	$-\Delta_f G°$(kJ/mol)	AgX	$-\Delta_f G°$(kJ/mol)
HF	273.2	AgF	193.8
HCl	95.09	AgCl	109.76
HBr	53.45	AgBr	96.90
HI	1.56	AgI	66.19

In the Laboratory

93. One material needed to make silicones is dichlorodimethylsilane, $(CH_3)_2SiCl_2$. It is made by treating silicon powder at about 300 °C with CH_3Cl in the presence of a copper-containing catalyst.

(a) Write a balanced equation for the reaction.

(b) Assume you carry out the reaction on a small scale with 2.65 g of silicon. To measure the CH_3Cl gas, you fill a 5.60-L flask at 24.5 °C. What pressure of CH_3Cl gas must you have in the flask to have the stoichiometrically correct amount of the compound?

(c) What mass of $(CH_3)_2SiCl_2$ can be produced from 2.65 g of Si and excess CH_3Cl?

94. Sodium borohydride, $NaBH_4$, reduces many metal ions to the metal.

(a) Write a balanced equation for the reaction of $NaBH_4$ with $AgNO_3$ in water to give silver metal, H_2 gas, boric acid, and sodium nitrate. (The chemistry of $NaBH_4$ is described in Section 21-6.)

(b) What mass of silver can be produced from 575 mL of 0.011 M $AgNO_3$ and 13.0 g of $NaBH_4$?

95. A common analytical method for hydrazine involves its oxidation with iodate ion, IO_3^-, in acid solution. In the process, hydrazine acts as a four-electron reducing agent.

$$N_2(g) + 5\ H_3O^+(aq) + 4\ e^- \rightarrow N_2H_5^+(aq) + 5\ H_2O(\ell) \qquad E° = -0.23\ V$$

Write the balanced equation for the reaction of hydrazine in acid solution ($N_2H_5^+$) with $IO_3^-(aq)$ to give N_2 and I_2. Calculate $E°$ for this reaction.

96. When 1.00 g of a white solid **A** is strongly heated, you obtain another white solid, **B**, and a gas. An experiment is carried out on the gas, showing that it exerts a pressure of 209 mm Hg in a 450-mL flask at 25 °C. Bubbling the gas into a solution of $Ca(OH)_2$ gives another white solid, **C**. If the white solid **B** is added to water, the resulting solution turns red litmus paper blue.

© Cengage Learning/Charles D. Winters

The salts $CaCl_2$, $SrCl_2$, and $BaCl_2$ were suspended in methanol. When the methanol is set ablaze, the heat of combustion causes the salts to emit light of characteristic wavelengths: Calcium salts are yellow; strontium salts are red; and barium salts are green-yellow.

Addition of aqueous HCl to the solution of **B** and evaporation of the resulting solution to dryness yield 1.055 g of a white solid **D**. When **D** is placed in a Bunsen burner flame, it colors the flame green. Finally, if the aqueous solution of **B** is treated with sulfuric acid, a white precipitate, **E**, forms. Identify the lettered compounds in the reaction scheme.

97. ▲ In 1937, R. Schwartz and M. Schmiesser prepared a yellow-orange bromine oxide (BrO_2) by treating Br_2 with ozone in a fluorocarbon solvent. Many years later, J. Pascal found that, on heating, this oxide decomposed to two other oxides, a less volatile golden yellow oxide (**A**) and a more volatile deep brown oxide (**B**). Oxide **B** was later identified as Br_2O. To determine the formula for oxide **A**, a sample was treated with sodium iodide. The reaction liberated iodine, which was titrated to an equivalence point with 17.7 mL of 0.065 M sodium thiosulfate.

$$I_2(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow 2\ I^-(aq) + S_4O_6^{2-}(aq)$$

Compound **A** was also treated with $AgNO_3$, and 14.4 mL of 0.020 M $AgNO_3$ was required to completely precipitate the bromine from the sample.

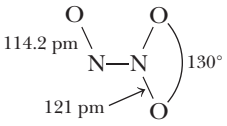
(a) What is the formula of the unknown bromine oxide **A**?
(b) Draw Lewis structures for **A** and Br_2O. Speculate on their molecular geometry.

98. A mixture of PCl_5 (12.41 g) and excess NH_4Cl was heated at 145 °C for 6 hours. The two reacted in equimolar amounts and evolved 5.14 L of HCl (at STP). Three substances (**A**, **B**, and **C**) were isolated from the reaction mixture. The three substances had the same elemental composition but differed in their molar mass. Substance **A** had a molar mass of 347.7 g/mol and **B** had a molar mass of 463.5 g/mol. Give the empirical and molecular formulas for **A** and **B** and draw a reasonable Lewis structure for **A**.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

99. Dinitrogen trioxide, N_2O_3, has the structure shown here.



The oxide is unstable, decomposing to NO and NO_2 in the gas phase at 25 °C.

$$N_2O_3(g) \rightarrow NO(g) + NO_2(g)$$

(a) Draw resonance structures for N_2O_3 and explain why one N—O bond distance is 114.2 pm, whereas the other two bonds are longer (121 pm) and nearly equal to each other.
(b) For the decomposition reaction, $\Delta_r H° = +40.5$ kJ/mol and $\Delta_r G° = -1.59$ kJ/mol. Calculate $\Delta S°$ and K for the reaction at 298 K.
(c) Calculate $\Delta_f H°$ for $N_2O_3(g)$.

100. ▲ The density of lead is 11.350 g/cm^3, and the metal crystallizes in a face-centered cubic unit cell. Estimate the radius of a lead atom.

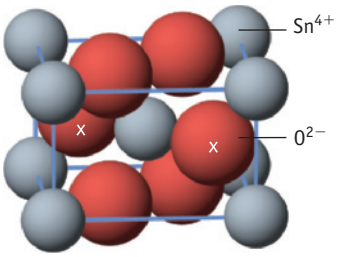
101. You have a 1.0-L flask that contains a mixture of argon and hydrogen. The pressure inside the flask is 745 mm Hg, and the temperature is 22 °C. Describe an experiment that you could use to determine the percentage of hydrogen in this mixture.

102. The boron atom in boric acid, $B(OH)_3$, is bonded to three —OH groups. In the solid state, the —OH groups are in turn hydrogen-bonded to —OH groups in neighboring molecules.

(a) Draw the Lewis structure for boric acid.
(b) What is the hybridization of the boron atom in the acid?
(c) Sketch a picture showing how hydrogen bonding can occur between neighboring molecules.

103. How would you extinguish a sodium fire in the laboratory? What is the worst thing you could do?

104. Tin(IV) oxide, cassiterite, is the main ore of tin. It crystallizes in a rutile-like unit cell with tin(IV) ions taking the place of Ti^{4+} ions (Study Question 12.4). (The O^{2-} ions marked x are wholly within the unit cell.)



(a) How many tin(IV) ions and oxide ions are there per unit cell of this oxide?
(b) Is it thermodynamically feasible to transform solid SnO_2 into liquid $SnCl_4$ by reaction of the oxide with gaseous HCl? What is the equilibrium constant for this reaction at 25 °C?

105. You are given a stoppered flask that contains hydrogen, nitrogen, or oxygen. Suggest an experiment you could do to identify the gas.

106. The structure of nitric acid is illustrated on page 835.

(a) Why are the N—O bonds the same length, and why are both shorter than the N—OH bond length?
(b) Rationalize the bond angles in the molecule.
(c) What is the hybridization of the central N atom? Which orbitals overlap to form the N—O π bond?

107. Assume an electrolysis cell that produces chlorine from aqueous sodium chloride operates at 4.6 V (with a current of 3.0×10^5 A). Calculate the number of kilowatt-hours of energy required to produce 1.00 kg of chlorine (1 kWh = 1 kilowatt-hour = 3.6×10^6 J).

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

108. Sodium metal is produced by electrolysis of molten sodium chloride. The cell operates at 7.0 V with a current of 25×10^3 A.

(a) What mass of sodium can be produced in 1 hour?
(b) How many kilowatt-hours of electricity are used to produce 1.00 kg of sodium metal (1 kWh = 3.6×10^6 J)?

109. The reduction potentials for the Group 3A metals, $E°$, are given below. What trend or trends do you observe in these data? What can you learn about the chemistry of the Group 3A elements from these data?

Half-Reaction	Reduction Potential ($E°$, V)
$Al^{3+}(aq) + 3\,e^- \longrightarrow Al(s)$	−1.66
$Ga^{3+}(aq) + 3\,e^- \longrightarrow Ga(s)$	−0.53
$In^{3+}(aq) + 3\,e^- \longrightarrow In(s)$	−0.338
$Tl^{3+}(aq) + 3\,e^- \longrightarrow Tl(s)$	+0.72

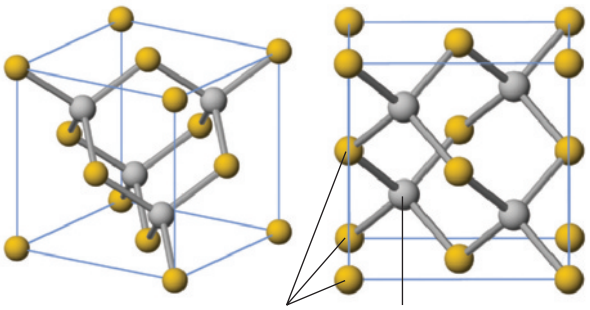
110. (a) Magnesium is obtained from seawater. If the concentration of Mg^{2+} in seawater is 0.050 M, what volume of seawater (in liters) must be treated to obtain 1.00 kg of magnesium metal? What mass of lime (CaO; in kilograms) must be used to precipitate the magnesium in this volume of seawater?
(b) When 1.2×10^3 kg of molten $MgCl_2$ is electrolyzed to produce magnesium, what mass (in kilograms) of metal is produced at the cathode? What is produced at the anode? What is the mass of this product? What is the total number of Faradays of electricity used in the process?
(c) One industrial process has an energy consumption of 18.5 kWh/kg of Mg. How many joules are required per mole (1 kWh = 1 kilowatt-hour = 3.6×10^6 J)? How does this energy compare with the energy of the following process?

$$MgCl_2(s) \rightarrow Mg(s) + Cl_2(g)$$

111. Comparing the chemistry of carbon and silicon.

(a) Write balanced chemical equations for the reactions of $H_2O(\ell)$ with CH_4 (forming CO_2 and H_2) and SiH_4 (forming SiO_2 and H_2).
(b) Using thermodynamic data, calculate the standard free energy change for the reactions in (a). Is either reaction product-favored at equilibrium?
(c) Look up the electronegativities of carbon, silicon, and hydrogen. What conclusion can you draw concerning the polarity of C—H and Si—H bonds?
(d) Carbon and silicon compounds with the formulas $(CH_3)_2CO$ (acetone) and $[(CH_3)_2SiO]_n$ (a silicone polymer) also have quite different structures. Draw Lewis structures for these species. This difference, along with the difference between structures of CO_2 and SiO_2, suggests a general observation about silicon compounds. Based on that observation, do you expect that a silicon compound with a structure similar to ethene (C_2H_4) exists?

112. ▲ Boron nitride, BN, has the same solid state structure as ZnS (see Figure 12.10).



You can consider it a face-centered cube of nitrogen atoms with boron atoms in one half of the tetrahedral holes of the lattice. If the density of this form of BN is 3.45 g/cm^3, what is the B−N bond length?

113. ▲ Xenon trioxide, XeO_3, reacts with aqueous base to form the xenate anion, $HXeO_4^-$. This ion reacts further with OH^- to form the perxenate anion, XeO_6^{4-}, in the following reaction:

$$2\ HXeO_4^-(aq) + 2\ OH^-(aq) \rightarrow XeO_6^{4-}(aq) + Xe(g) + O_2(g) + 2\ H_2O(\ell)$$

Identify the elements that are oxidized and reduced in this reaction. You will note that the equation is balanced with respect to the number of atoms on either side. Verify that the redox part of this equation is also balanced, that is, that the extents of oxidation and reduction are also equal.

The Chemistry of the Transition Elements

Chapter Outline

22-1 Properties of the Transition Elements

22-2 Metallurgy

22-3 Coordination Compounds

22-4 Structures of Coordination Compounds

22-5 Bonding in Coordination Compounds

22-6 Colors of Coordination Compounds

LIFE-SAVING COPPER If you are admitted to a hospital in the United States, there is a 1 in 20 chance you will develop an infection. And if you do become infected, there is a 1 in 20 chance you will die from that infection. The U.S. Centers for Disease Control and Prevention (CDC) estimates that hospital-acquired infections kill about 100,000 people in the United States and cost almost $50 billion annually. Clearly it is in our interest to prevent these infections, and recent clinical trials point the way to simple and low-cost ways to do so.

Dr. Michael Schmidt of the Medical University of South Carolina said that "Bacteria present on ICU room surfaces are probably responsible for 35–80 percent of patient infections, demonstrating how critical it is to keep hospitals clean." Therefore, in addition to following normal cleaning processes, the hospital carried out a study in which they covered bed rails, tray tables, chair arms, call

Chapter Goals

See Chapter Goals Revisited (page 894) for Study Questions keyed to these goals.

UNDERSTAND

- Ligand field theory description of metal-ligand bonding in coordination compounds.
- Isomerism and its occurrence in coordination chemistry.
- How color and magnetism are related to the electronic structure of a complex.
- How spectroscopy and magnetism can be used to identify high- and low-spin complexes.

DO

- Given the formula for a coordination complex, identify the metal and its oxidation state, the ligands, the coordination number and coordination geometry, and the overall charge on the complex.
- Given the molecular formula of a complex, determine whether isomers are possible, and draw their structures.
- Given a formula, name a complex; given a name of a complex, write its formula.
- Draw an energy level diagram representing splitting of the metal *d* orbitals by the ligand field.
- Apply the principles of stoichiometry, thermodynamics, and equilibrium to transition metal compounds.

REMEMBER

- General chemical and physical properties of common transition metal elements.
- The terminology of coordination chemistry: coordination number and coordination geometry, ligand, chelate, bidentate.
- The terminology of ligand field theory: low spin and high spin, ligand field splitting.
- The names and formulas for common ligands.

buttons, and IV poles with various copper alloys. (The alloys varied from 75% to 99% copper.) In all they covered 282 objects in copper alloys in 32 rooms and compared the results with 288 noncovered items in 27 rooms. (Similar trials were done in two other large hospitals.) Copper coatings reduced the "microbial burden" (MB) of pathogens by 99% on bed rails and call buttons and by 38% on chair arms. Copper was found to be effective against the following bacteria, among others:

(a) *Staphylococcus aureus*, a bacterium commonly found in hospitals.
(b) Methicillin-resistant *Staphylococcus aureus* (MRSA). This is a virulent strain of antibiotic-resistant bacteria and a common cause of hospital infections.
(c) Vancomycin-resistant *Enterococcus* (VRE), the second leading cause of hospital-acquired infections.

The research team noted that "although MRSA and VRE were frequently isolated from non-copper objects, they were never isolated from copper objects over the study period." Now, because of the apparent effectiveness of using copper on surfaces where the most human contact occurs, hospitals and other medical facilities are expanding their use of copper alloys.

But why did we not recognize this before? Hippocrates (460–370 BC), the father of medicine, recommended the use of copper to treat leg ulcers related to varicose veins. In Roman times, Pliny used copper oxide and honey to treat intestinal worms. More recently scientists from Britain and India investigated a long-held belief among people

in India that storing water in brass pitchers can ward off illness. (Brass is an alloy of copper and zinc.) They filled brass pitchers with previously sterile water to which they had added *E. coli* (a bacterium that lives in the lower intestine of many warm-blooded animals and consequently is found in their feces). Other brass pitchers were filled with contaminated river water from India. In both cases, they found fecal bacteria counts dropped from as high as 1,000,000 bacteria per milliliter to zero in 2 days. In contrast, bacteria levels stayed high in plastic or earthenware pots.

The underlying mechanism by which bacteria are destroyed by copper ions is not yet well understood, but there is research activity on this question in academic laboratories around the world.

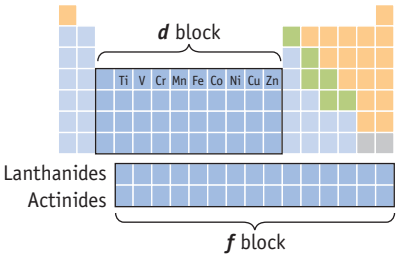
Study Questions related to this story on copper compounds are: 22.58 and 22.59.

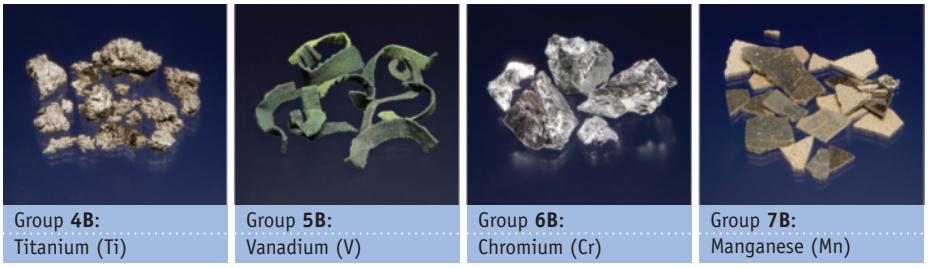
The transition elements are the large block of elements in the central portion of the periodic table, bridging the *s*-block elements at the left and the *p*-block elements on the right (Figure 22.1). The transition elements are often divided into two groups, depending on the valence electrons involved in their chemistry. The first group are the ***d*-block elements**, because their occurrence in the periodic table coincides with the filling of the *d* orbitals. The second group are the ***f*-block elements**, characterized by filling of the *f* orbitals. Contained within this group of elements are two subgroups: the *lanthanides*, elements that occur between La and Hf, and the *actinides*, elements that occur between Ac and Rf.

This chapter focuses primarily on the *d*-block elements, and within this group we concentrate mainly on the elements in the fourth period, that is, the elements of the first transition series, scandium to zinc.

22-1 Properties of the Transition Elements

The *d*-block metals include elements with a wide range of properties. They encompass the most common metal used in construction and manufacturing (iron), metals valued for their beauty (gold, silver, and platinum), and metals used in coins (nickel, copper, and zinc). There are metals used in modern technology (titanium) and metals known and used in early civilizations (copper, silver, gold, and iron). The *d*-block contains the





Group **4B:** Titanium (Ti)

Group **5B:** Vanadium (V)

Group **6B:** Chromium (Cr)

Group **7B:** Manganese (Mn)

Group **8B:** Iron (Fe)

Group **8B:** Cobalt (Co)

Group **8B:** Nickel (Ni)

Group **1B:** Copper (Cu)

Group **2B:** Zinc (Zn)

(a) Paint pigments: yellow, CdS; green, Cr_2O_3; white, TiO_2 and ZnO; purple, $Mn_3(PO_4)_2$; blue, Co_2O_3 and Al_2O_3; ochre, Fe_2O_3.

(b) Small amounts of transition metal compounds are used to color glass: blue, Co_2O_3; green, copper or chromium oxides; purple, nickel or cobalt oxides; red, copper oxide; iridescent green, uranium oxide.

(c) Traces of transition metal ions are responsible for the colors of green jade (iron), red corundum (chromium), blue azurite, blue-green turquoise (copper), and purple amethyst (iron).

Photos: © Cengage Learning/Charles D. Winters

FIGURE 22.2 Colorful chemistry. Transition metal compounds have a wide variety of colors.

densest elements (osmium, $d = 22.49$ g/cm^3, and iridium, $d = 22.41$ g/cm^3), the metals with the highest and lowest melting points (tungsten, mp = 3410 °C, and mercury, mp = −38.9 °C), and one of just two elements with atomic numbers less than 83 that have only radioactive isotopes [technetium (Tc), atomic number 43; promethium (Pm), atomic number 61, in the *f*-block].

With the exception of mercury, the transition elements are solids. They have a metallic sheen and conduct electricity and heat. They react with various oxidizing agents to give ionic compounds, although there is considerable variation in such reactions among the elements. Because silver, gold, and platinum resist oxidation, for example, they are used for jewelry and decorative items.

Certain *d*-block elements are important in living organisms. Cobalt is the crucial element in vitamin B_{12}, which is part of a catalyst essential for several biochemical reactions. Hemoglobin and myoglobin, oxygen-carrying and storage proteins, contain iron. Molybdenum and iron, together with sulfur, form the reactive portion of nitrogenase, a biological catalyst used by nitrogen-fixing organisms to convert atmospheric nitrogen into ammonia.

Many transition metal compounds are highly colored, which makes them useful as pigments in paints and dyes (Figure 22.2). Prussian blue, $Fe_4[Fe(CN)_6]_3 \cdot 14\ H_2O$, is a "bluing agent" used in engineering blueprints and in the laundry to brighten yellowed white cloth. A common pigment used by artists (cadmium yellow) contains cadmium sulfide, CdS, and the white in most white paints is titanium(IV) oxide, TiO_2.

The presence of transition metal ions in crystalline silicates or alumina transforms these common materials into gemstones. Iron(II) ions produce the yellow color in citrine, and chromium(III) ions produce the red color of a ruby. Transition metal compounds in small quantities add color to glass. Blue glass contains a small amount of a cobalt(III) oxide, and addition of chromium(III) oxide to glass gives a green color. Old window panes sometimes take on a purple color over time as a consequence of oxidation of traces of manganese(II) ion present in the glass to permanganate ion (MnO_4^-).

In the next few pages, we will examine the properties of the transition elements, concentrating on the underlying principles that govern these properties.

© Cengage Learning/Charles D. Winters

Prussian blue. The deep blue compound called Prussian blue has the formula $Fe_4[Fe(CN)_6]_3 \cdot 14\ H_2O$. The color arises from electron transfer between Fe(II) and Fe(III) ions in the compound.

Electron Configurations

Because chemical behavior is related to electron structure, it is important to know the electron configurations of the *d*-block elements (Table 22.1) and their common ions (◀ Sections 7-3 and 7-4). Recall that the configuration of these metals has the

Table 22.2 Products from Reactions of the Elements in the First Transition Series with O_2, Cl_2, or Aqueous HCl

Element	Reaction with O_2*	Reaction with Cl_2	Reaction with Aqueous HCl
Scandium	Sc_2O_3	$ScCl_3$	$Sc^{3+}(aq)$
Titanium	TiO_2	$TiCl_4$	$Ti^{3+}(aq)$
Vanadium	V_2O_5	VCl_4	NR†
Chromium	Cr_2O_3	$CrCl_3$	$Cr^{2+}(aq)$
Manganese	MnO_2	$MnCl_2$	$Mn^{2+}(aq)$
Iron	Fe_2O_3	$FeCl_3$	$Fe^{2+}(aq)$
Cobalt	Co_2O_3	$CoCl_2$	$Co^{2+}(aq)$
Nickel	NiO	$NiCl_2$	$Ni^{2+}(aq)$
Copper	CuO	$CuCl_2$	NR†
Zinc	ZnO	$ZnCl_2$	$Zn^{2+}(aq)$

*Product obtained with excess oxygen.
†NR = no reaction.

general form [noble gas core]$(n - 1)d^b ns^a$; that is, valence electrons for the transition elements reside in the *ns* and $(n - 1)d$ subshells.

Oxidation and Reduction

A characteristic chemical property of all metals is that they undergo oxidation by a wide range of oxidizing agents such as oxygen, the halogens, and aqueous acids. Standard reduction potentials for the elements of the first transition series can be used to predict which elements will be oxidized by a given oxidizing agent in aqueous solution. For example, all of these metals except vanadium and copper are oxidized by aqueous HCl (Table 22.2). Oxidation, which dominates the chemistry of these elements, is sometimes highly undesirable (see *A Closer Look: Corrosion of Iron,* page 863).

When a transition metal is oxidized, the outermost *s* electrons are removed, followed by one or more *d* electrons. With a few exceptions, transition metal ions have the electron configuration [noble gas core]$(n - 1)d^x$. In contrast to ions formed by main group elements, transition metal cations often possess unpaired electrons, resulting in paramagnetism (◀ Section 7-5). They are frequently colored as well, due to the absorption of light in the visible region of the electromagnetic spectrum. Color and magnetism figure prominently in a discussion of the properties and bonding of these elements, as you shall see shortly.

In the first transition series, the most commonly encountered metal ions have oxidation numbers of +2 and +3 (Table 22.2). With iron, for example, oxidation converts Fe([Ar]$3d^6 4s^2$) to either Fe^{2+}([Ar]$3d^6$) or Fe^{3+}([Ar]$3d^5$). Iron reacts with chlorine to give $FeCl_3$, and it reacts with aqueous acids to produce $Fe^{2+}(aq)$ and H_2 (Figure 22.3). Despite the preponderance of 2+ and 3+ ions in compounds of the first transition metal series, the range of possible oxidation states for these compounds is broad (Figure 22.4). Earlier in this text, we encountered chromium with a +6 oxidation number (CrO_4^{2-}, $Cr_2O_7^{2-}$), manganese with an oxidation number of +7 (MnO_4^-), silver and copper as 1+ ions, and vanadium oxidation numbers that can range from +5 to +2 (◀ Figure 19.3).

(b) Steel wool reacts with chlorine gas, Cl_2.

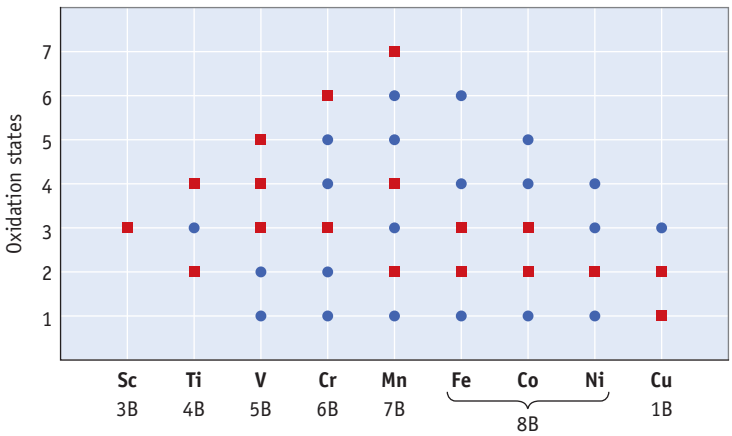
(c) Iron chips react with aqueous HCl.

FIGURE 22.3 Typical reactions of transition metals. These metals react with oxygen, with halogens, and with acids under appropriate conditions.

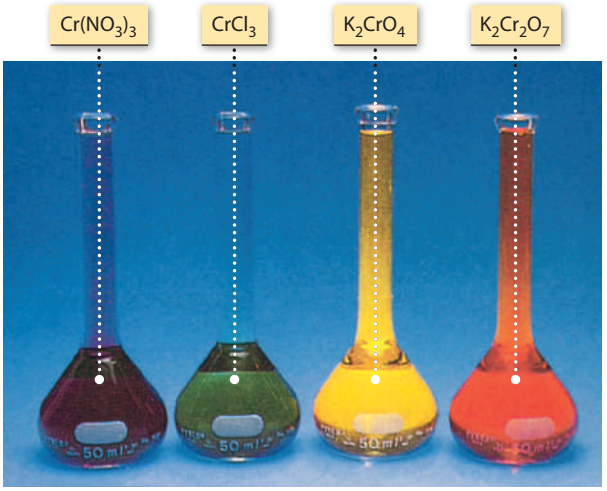
Higher oxidation numbers are more common in compounds of the elements in the second and third transition series. For example, the naturally occurring sources of molybdenum and tungsten are the ores molybdenite (MoS_2) and wolframite (WO_3). This general trend is carried over in the *f*-block. The lanthanides form primarily 3+ ions. In contrast, actinide elements usually have higher oxidation numbers in their compounds; +4 and even +6 are typical. For example, UO_3 is a common oxide of uranium, and UF_6 is a compound important in processing uranium fuel for nuclear reactors (▶ Section 25-6).

Periodic Trends in the *d* Block: Size, Density, Melting Point

Let us look at three important physical properties of the transition elements that vary periodically: atomic radii, density, and melting point.



(a) The most common oxidation states are indicated with *red squares;* less common oxidation states are indicated with *blue dots.*



© Cengage Learning/Charles D. Winters

(b) Aqueous solutions of chromium compounds with two different oxidation numbers: +3 in $Cr(NO_3)_3$ (violet) and $CrCl_3$ (green), and +6 in K_2CrO_4 (yellow) and $K_2Cr_2O_7$ (orange). The two Cr(III) species have different colors in solution because there are different complex ions in solution. The complex ion in the purple solution is $[Cr(H_2O)_6]^{3+}$; the complex ion in the green solution is $[Cr(H_2O)_4Cl_2]^{+}$.

Metal Atom Radii

The radii of the transition elements vary over a fairly narrow range, with a small decrease to a minimum being observed around the middle of this group of elements (◀ Figure 7.8). This similarity of radii can be understood based on electron configurations. Atom size is determined by the electrons in the outermost orbital, which for these elements is the *ns* orbital ($n = 4$, 5, or 6). Progressing from left to right in the periodic table, the size decline expected from increasing the number of protons in the nucleus is mostly canceled out by an opposing effect, repulsion from additional electrons in the $(n - 1)d$ orbitals.

The radii of the *d*-block elements in the fifth and sixth periods in each group are almost identical. The reason is that the lanthanide elements immediately precede the third series of *d*-block elements. The filling of 4*f* orbitals is accompanied by a steady contraction in size, consistent with the general trend of decreasing size from left to right in the periodic table. At the point where the 5*d* orbitals begin to fill again, the radii have decreased to a size similar to that of elements in the previous period. The decrease in size that results from the filling of the 4*f* orbitals is called the **lanthanide contraction**.

The similar sizes of the second and third series *d*-block elements have significant consequences for their chemistry. For example, the "platinum group metals" (Ru, Os, Rh, Ir, Pd, and Pt) form similar compounds. Thus, it is not surprising that minerals containing these metals are found in the same geological zones on Earth. Nor is it surprising that it is difficult to separate these elements from one another.

Density

The variation in metal radii causes the densities of the transition elements to first increase and then decrease across a period (Figure 22.5, *left*). Although the overall change in radii among these elements is small, the effect is magnified because the volume is actually changing with the cube of the radius [$V = (4/3)\pi r^3$].

The lanthanide contraction explains why elements in the sixth period have the highest densities. The relatively small radii of sixth-period transition metals, combined with the fact that their atomic masses are considerably larger than their counterparts in the fifth period, causes sixth-period metal densities to be very large.

Melting Point

The melting point of any substance reflects the forces of attraction between the atoms, molecules, or ions that compose the solid. With transition elements, the melting points rise to a maximum around the middle of the series (Figure 22.5, *right*), then

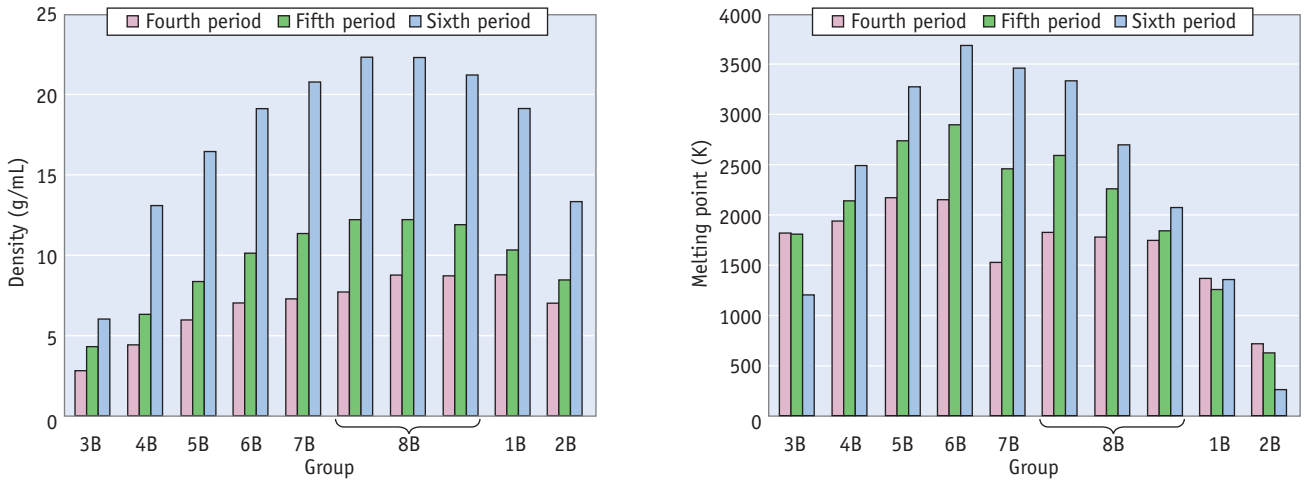

FIGURE 22.5 Periodic properties in the transition series. Density *(left)* and melting point *(right)* of the *d*-block elements.

A CLOSER LOOK Corrosion of Iron

It is hard not to be aware of corrosion. Those of us who live in the northern part of the United States are well aware of the problems of rust on our automobiles. It is estimated that 20% of iron production each year goes solely to replace iron that has rusted away.

Qualitatively, we describe corrosion as the deterioration of metals by a product-favored oxidation reaction. The corrosion of iron, for example, converts iron metal to red-brown rust, which is hydrated iron(III) oxide, $Fe_2O_3 \cdot H_2O$. This process requires both air and water, and it is enhanced if the water contains dissolved ions and if the metal is stressed (e.g., if it has dents, cuts, and scrapes on the surface).

The corrosion process occurs in what is essentially a small electrochemical cell. There is an anode and a cathode, an electrical connection between the two (the metal itself), and an electrolyte in contact with both anode and cathode. When a metal corrodes, the metal is oxidized on anodic areas of the metal surface.

Anode, oxidation $\quad M(s) \longrightarrow M^{n+} + n\ e^-$

The electrons are consumed by several possible half-reactions in cathodic areas.

Cathode, reduction

$$2\ H_3O^+(aq) + 2\ e^- \longrightarrow H_2(g) + 2\ H_2O(\ell)$$

$$2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)$$

$$O_2(g) + 2\ H_2O(\ell) + 4\ e^- \longrightarrow 4\ OH^-(aq)$$

The rate of iron corrosion is controlled by the rate of the cathodic process. Of the three possible cathodic reactions, the one that is fastest is determined by acidity and the amount of oxygen present. If little or no oxygen is present—as when a piece of iron is buried in soil such as moist clay—hydronium ions or water are reduced, and $H_2(g)$ and hydroxide ions are the products. Iron(II) hydroxide is relatively insoluble and will precipitate on the metal surface, inhibiting the further formation of Fe^{2+}.

Anode	$Fe(s) \longrightarrow Fe^{2+}(aq) + 2\ e^-$
Cathode	$2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)$
Precipitation	$Fe^{2+}(aq) + 2\ OH^-(aq) \longrightarrow Fe(OH)_2(s)$
Net reaction	$Fe(s) + 2\ H_2O(\ell) \longrightarrow H_2(g) + Fe(OH)_2(s)$

If both water and O_2 are present, the chemistry of iron corrosion is somewhat different, and the corrosion reaction is about 100 times faster than without oxygen.

Anode	$2\ Fe(s) \longrightarrow 2\ Fe^{2+}(aq) + 4\ e^-$
Cathode	$O_2(g) + 2\ H_2O(\ell) + 4\ e^- \longrightarrow 4\ OH^-(aq)$
Precipitation	$2\ Fe^{2+}(aq) + 4\ OH^-(aq) \longrightarrow 2\ Fe(OH)_2(s)$
Net reaction	$2\ Fe(s) + 2\ H_2O(\ell) + O_2(g) \longrightarrow 2\ Fe(OH)_2(s)$

If oxygen is present but not in excess, further oxidation of the iron(II) hydroxide leads to the formation of magnetic iron oxide Fe_3O_4, (which can be thought of as a mixed oxide of Fe_2O_3 and FeO).

$$6\ Fe(OH)_2(s) + O_2(g) \longrightarrow \underset{\text{green hydrated magnetite}}{2\ Fe_3O_4 \cdot H_2O(s)} + 4\ H_2O(\ell)$$

$$Fe_3O_4 \cdot H_2O(s) \longrightarrow H_2O(\ell) + \underset{\text{black magnetite}}{Fe_3O_4(s)}$$

It is the black magnetite that you find coating an iron object that has corroded by resting in moist soil.

If the iron object has free access to oxygen and water, as in the open or in flowing water, red-brown iron(III) oxide will form.

$$4\ Fe(OH)_2(s) + O_2(g) \longrightarrow \underset{\text{red-brown}}{2\ Fe_2O_3 \cdot H_2O(s)} + 2\ H_2O(\ell)$$

This is the familiar rust you see on cars and buildings and the substance that colors the water red in some mountain streams or in your home.

descend. Again, the element electron configurations provide us with an explanation. The variation in melting points indicates that the strongest metallic bonds occur when the *d* subshell is about half filled. This is also the point at which the largest number of electrons occupy the bonding molecular orbitals in the metal. (See the discussion of bonding in metals in Section 12-4.)

REVIEW & CHECK FOR SECTION 22-1

1. What is the maximum oxidation number that manganese can exhibit in its compounds?

   (a) +3 (b) +4 (c) +5 (d) +6 (e) +7

2. The "lanthanide contraction" is often given as an explanation for the fact that the sixth period transition elements have

   (a) densities smaller than that of the fifth period transition elements.

   (b) atomic radii that are similar to the fifth period transition elements.

   (c) melting points that are lower than the fifth period transition elements.

22-2 Metallurgy

Most metals are found in nature as oxides, sulfides, halides, carbonates, or other ionic compounds (Figure 22.6), but some such as copper, silver, and gold can occur uncombined. Some metal-containing mineral deposits have little economic value, either because the concentration of the metal is too low or because the metal is difficult to separate from impurities. The relatively few minerals from which elements can be obtained profitably are called *ores*. **Metallurgy** is the general name given to the process of obtaining metals from their ores.

Very few ores are chemically pure substances. Instead, the desired mineral is usually mixed with large quantities of impurities such as sand and clay, called **gangue** (pronounced "gang"). Generally, the first step in a metallurgical process is to separate the mineral from the gangue. Then the ore is converted to the metal, a reduction process. Pyrometallurgy and hydrometallurgy are two methods of recovering metals from their ores. As the names imply, **pyrometallurgy** involves high temperatures and **hydrometallurgy** uses aqueous solutions (and thus is limited to

Copper occurs in nature as the metal (native copper) and as minerals such as blue azurite [2 $CuCO_3 \cdot Cu(OH)_2$] and green malachite [$CuCO_3 \cdot Cu(OH)_2$].

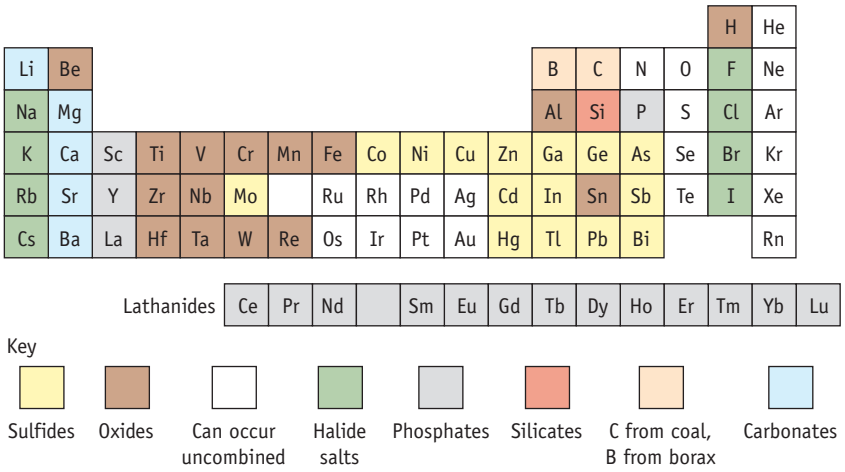

FIGURE 22.6 Sources of the elements. A few transition metals, such as copper and gold, occur in nature as the metal. Most other elements are found naturally as oxides, sulfides, or other salts.

the relatively low temperatures at which water is a liquid). Iron and copper metallurgy illustrate these two methods of metal production.

Pyrometallurgy: Iron Production

The production of iron from its ores is carried out in a blast furnace (Figure 22.7). The furnace is charged with a mixture of ore (usually hematite, Fe_2O_3), coke (which is primarily carbon), and limestone ($CaCO_3$). A blast of hot air forced in at the bottom of the furnace causes the coke to burn with such an intense heat that the temperature at the bottom is almost 1500 °C. The quantity of air input is controlled so that carbon monoxide is the primary product. Both carbon and carbon monoxide participate in the reduction of iron(III) oxide to give impure metal.

$$Fe_2O_3(s) + 3\ C(s) \longrightarrow 2\ Fe(\ell) + 3\ CO(g)$$

$$Fe_2O_3(s) + 3\ CO(g) \longrightarrow 2\ Fe(\ell) + 3\ CO_2(g)$$

Much of the carbon dioxide formed in the reduction process (and from heating limestone) is reduced on contact with unburned coke and produces carbon monoxide, which can then function as a reducing agent.

$$CO_2(g) + C(s) \longrightarrow 2\ CO(g)$$

The molten iron flows down through the furnace and collects at the bottom, where it is tapped off through an opening in the side. This impure iron is called *cast iron* or *pig iron*. Usually, the impure metal is either brittle or soft (undesirable properties for most uses) due to the presence of impurities such as elemental carbon, phosphorus, and sulfur.

Iron ores generally contain silicate minerals and silicon dioxide. Lime (CaO), formed when limestone is heated, reacts with these materials to give calcium silicate.

$$SiO_2(s) + CaO(s) \longrightarrow CaSiO_3(\ell)$$

Coke: A Reducing Agent Coke is made by heating coal in a tall, narrow oven that is sealed to keep out oxygen. Heating drives off volatile chemicals, including benzene and ammonia. What remains is nearly pure carbon.

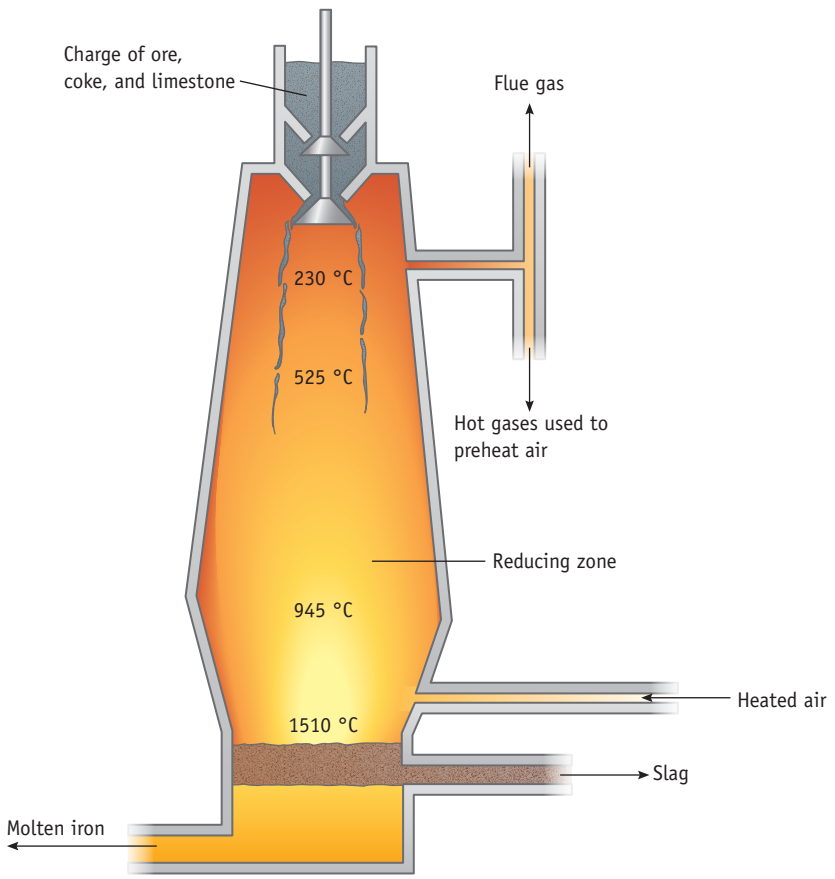

FIGURE 22.7 A blast furnace. The largest modern furnaces have hearths 14 meters in diameter. They can produce as much as 10,000 tons of iron per day.

FIGURE 22.8 Molten iron being poured from a basic oxygen furnace.

(This is an acid–base reaction because CaO is a basic oxide and SiO_2 is an acidic oxide.) The calcium silicate, molten at the temperature of the blast furnace and less dense than molten iron, floats on the iron. Other nonmetal oxides dissolve in this layer and the mixture, called *slag*, is easily removed.

Pig iron from the blast furnace may contain as much as 4.5% carbon, 0.3% phosphorus, 0.04% sulfur, 1.5% silicon, and some other elements as well. The impure iron must be purified to remove these nonmetal components. Several processes are available to accomplish this task, but the most important uses the *basic oxygen furnace* (Figure 22.8). The process in the furnace removes much of the carbon and all of the phosphorus, sulfur, and silicon. Pure oxygen is blown into the molten pig iron and oxidizes phosphorus to P_4O_{10}, sulfur to SO_2, and carbon to CO_2. These nonmetal oxides either escape as gases or react with basic oxides such as CaO that are added or are used to line the furnace. For example,

$$P_4O_{10}(g) + 6\ CaO(s) \longrightarrow 2\ Ca_3(PO_4)_2(\ell)$$

The result is ordinary *carbon steel*. Almost any degree of flexibility, hardness, strength, and malleability can be achieved in carbon steel by reheating and cooling in a process called *tempering* (see *Case Study: High-Strength Steel*). The resulting material can then be used in a wide variety of applications. The major disadvantages of carbon steel are that it corrodes easily and that it loses its properties when heated strongly.

Other transition metals, such as chromium, manganese, and nickel, can be added during the steel-making process, giving *alloys* (solids made up of two or more metals) that have specific physical, chemical, and mechanical properties. One well-known alloy is stainless steel, which contains 18% to 20% Cr and 8% to 12% Ni. Stainless steel is much more resistant to corrosion than carbon steel. Another alloy of iron is alnico V. Used in loudspeaker magnets because of its permanent magnetism, it contains five elements: Al (8%), Ni (14%), Co (24%), Cu (3%), and Fe (51%).

Hydrometallurgy: Copper Production

In contrast to iron ores, which are mostly oxides, most copper minerals are sulfides. Copper-bearing minerals include chalcopyrite ($CuFeS_2$), chalcocite (Cu_2S), and covellite (CuS). Because ores containing these minerals generally have a very low percentage of copper, enrichment is necessary. This step is carried out by a process known as *flotation*. First, the ore is finely powdered. Next, oil is added and the mixture is agitated with soapy water in a large tank (Figure 22.9). At the same time, compressed air is forced through the mixture, so that the lightweight, oil-covered

CASE STUDY High-Strength Steel

A few decades ago if you rolled a car over or suffered a front end or side collision, you were likely to be seriously injured or killed. In recent years, though, the use of seat belts and air bags has greatly increased survivability. However, there is an additional factor—the steels used in cars have improved greatly and have led to both stronger frames and energy-absorbing front ends. At the same time cars are lighter and, partly as a result, more fuel-efficient. Much of this is due to the "design" of better steel.

Iron and steel are still made the same way they have always been. Iron ore is reduced with carbon to produce raw iron, and this is then heated in a "basic oxygen furnace" to remove impurities. Stronger steels were traditionally produced by adding very small amounts of other metals at this point to produce alloys that have very specific properties, but this can be expensive. So, the steel industry has developed new methods for producing steels that are less expensive.

When steel is produced, it is not a single, large crystal of iron atoms neatly arranged in a lattice. Rather, it consists of grains or crystallites of iron in various forms as well as carbon. The characteristics of this material can be changed by rolling a slab at room temperature, by annealing, or by quenching. Quenching refers to a process in which the steel slab is rolled at room temperature, heated to a high temperature, and then rapidly cooled or "quenched" in cold water.

Pure iron (ferrite) has a unit cell consisting only of iron atoms (Figure B); it is ferromagnetic. Only a small amount of carbon can dissolve in ferrite, but, on heating, ferrite undergoes a phase transition and can now incorporate carbon. This new form with an embedded carbon atom is the *austenite form*. When the steel is then quenched, another rearrangement occurs, this time to the martensite form, still with an embedded carbon atom.

Steel that has gone through this process will consist of crystallites of ferrite, austenite, and martensite. Depending on the precise conditions used, the proportion of these can vary, and so can the strength of the steel. For example, steel with a high proportion of martensite is very strong and is used in car bumpers.

Some steels may have added boron, which gives an ultra-high-strength steel that can be used in door pillars and beams. The lives of passengers can be saved in the event of a rollover.

Bill Pugliano/Getty Images

FIGURE A Modern high-strength steels can save the lives of passengers in serious accidents such as rollovers.

Questions:

1. What is the unit cell of ferrite?
2. Describe the unit cell of austenite.
3. What change has occurred on going from the austenite form to the martensite form?

Answers to these questions are available in Appendix N.

Reference:

New York Times, September 25, 2009, page D1.

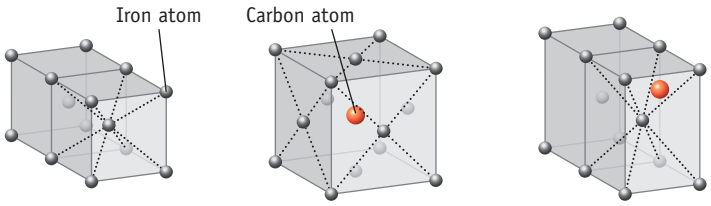

FIGURE B **The structures of various iron species.**

copper sulfide particles are carried to the top as a frothy mixture. The heavier gangue settles to the bottom of the tank, and the copper-laden froth is skimmed off.

Hydrometallurgy can be used to obtain copper from an enriched ore. In one method, enriched chalcopyrite ore is treated with a solution of copper(II) chloride. A reaction ensues that leaves copper in the form of solid, insoluble CuCl, which is easily separated from the iron that remains in solution as aqueous $FeCl_2$.

$$CuFeS_2(s) + 3\ CuCl_2(aq) \longrightarrow 4\ CuCl(s) + FeCl_2(aq) + 2\ S(s)$$

Aqueous NaCl is then added, and CuCl dissolves upon formation of the soluble complex ion $[CuCl_2]^-$.

$$CuCl(s) + Cl^-(aq) \longrightarrow [CuCl_2]^-(aq)$$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Copper(I) compounds in solution are unstable with respect to Cu(0) and Cu(II). Thus, $[CuCl_2]^-$ disproportionates to the metal and $CuCl_2$, and the latter is used to treat further ore.

$$2\ [CuCl_2]^-(aq) \longrightarrow Cu(s) + Cu^{2+}(aq) + 4\ Cl^-(aq)$$

Approximately 10% of the copper produced in the United States is obtained with the aid of bacteria. Acidified water is sprayed onto copper-mining wastes that contain low levels of copper. As the water trickles down through the crushed rock, the bacterium *Thiobacillus ferrooxidans* breaks down the iron sulfides in the rock and converts iron(II) to iron(III). Iron(III) ions oxidize the sulfide ion of copper sulfide to sulfate ions, leaving copper(II) ions in solution. Then the copper(II) ion is reduced to metallic copper by reaction with iron.

$$Cu^{2+}(aq) + Fe(s) \longrightarrow Cu(s) + Fe^{2+}(aq)$$

The purity of the copper obtained via these metallurgical processes is about 99%, but this is not acceptable because even traces of impurities greatly diminish the electrical conductivity of the metal. Consequently, a further purification step is needed—one involving electrolysis (Figure 22.9). Thin sheets of pure copper metal and slabs of impure copper are immersed in a solution containing $CuSO_4$ and H_2SO_4. The pure copper sheets serve as the cathode of an electrolysis cell, and the impure slabs are the anode. Copper in the impure sample is oxidized to copper(II) ions at the anode, and copper(II) ions in solution are reduced to pure copper at the cathode.

REVIEW & CHECK FOR SECTION 22-2

1. In the reaction between $CuFeS_2(s)$ and $CuCl_2(aq)$, what element is reduced and what element is oxidized?

   (a) Sulfur is reduced, iron is oxidized.
   (b) Copper is reduced, sulfur is oxidized.
   (c) Sulfur is reduced, copper is oxidized.
   (d) This is not a redox reaction.

2. What is the most common form in which iron is found in the Earth's crust?

   (a) Iron is found in elemental form
   (b) Iron oxide
   (c) Iron sulfide
   (d) Iron silicate

22-3 Coordination Compounds

When metal salts dissolve, water molecules cluster around the ions (◀ Figure 3.7). The negative end of each polar water molecule is attracted to the positively charged metal ion, and the positive end of the water molecule is attracted to the anion. As noted earlier (◀ Section 11-2), the energy of the ion–solvent interaction (solvation energy) is an important aspect of the solution process. But there is much more to this story.

Complexes and Ligands

A green solution formed by dissolving nickel(II) chloride in water contains $Ni^{2+}(aq)$ and $Cl^-(aq)$ ions (Figure 22.10). If the solvent is removed, a green crystalline solid is obtained. The formula of this solid is often written as $NiCl_2 \cdot 6\ H_2O$, and the compound is called nickel(II) chloride hexahydrate. Addition of ammonia to the aqueous nickel(II) chloride solution gives a lilac-colored solution from which another compound, $NiCl_2 \cdot 6\ NH_3$, can be isolated. This formula looks very similar to the formula for the hydrate, with ammonia substituted for water.

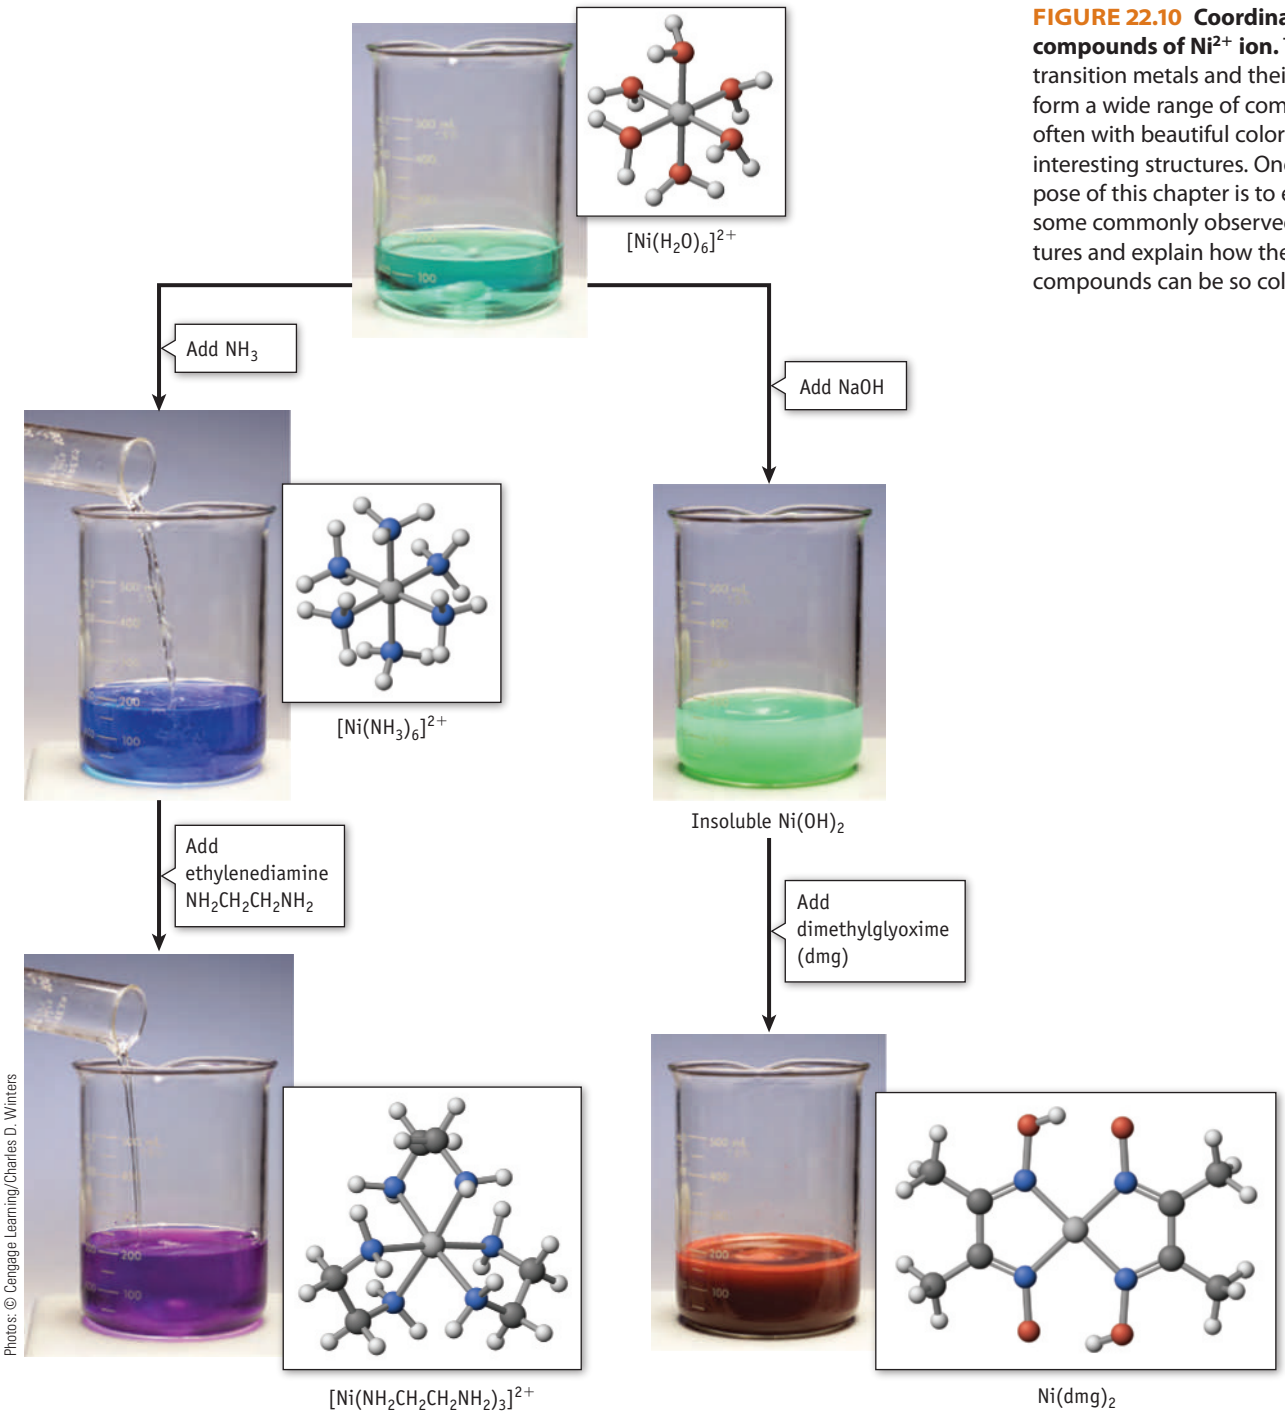

FIGURE 22.10 Coordination compounds of Ni^{2+} ion. The transition metals and their ions form a wide range of compounds, often with beautiful colors and interesting structures. One purpose of this chapter is to explore some commonly observed structures and explain how these compounds can be so colorful.

What are these two nickel species? The formulas identify the compositions of the compounds but fail to give information about their structures. Because properties of compounds derive from their structures, we need to evaluate the structures in more detail. Typically, metal compounds are ionic, and solid ionic compounds have structures with cations and anions arranged in a regular array. The structure of hydrated nickel(II) chloride contains cations with the formula $[Ni(H_2O)_6]^{2+}$ and chloride anions. The structure of the ammonia-containing compound is similar to the hydrate; it is made up of $[Ni(NH_3)_6]^{2+}$ cations and chloride anions.

$[Ni(NH_3)_6]^{2+}$

FIGURE 22.11 A coordination complex. In the $[Ni(NH_3)_6]^{2+}$ ion, the ligands are NH_3 molecules. Because the metal has a 2+ charge and the ligands have no charge, the charge on the complex ion is 2+.

Ligands Are Lewis Bases Ligands are Lewis bases because they furnish the electron pair; the metal ion is a Lewis acid because it accepts electron pairs (◀ Section 16-10). Thus, the coordinate covalent bond between ligand and metal can be viewed as a Lewis acid–Lewis base interaction.

Bidentate Ligands All common bidentate ligands bind to *adjacent* sites on the metal.

Ions such as $[Ni(H_2O)_6]^{2+}$ and $[Ni(NH_3)_6]^{2+}$, in which a metal ion and either water or ammonia molecules compose a single structural unit, are examples of **coordination complexes**, also known as **complex ions** (Figure 22.11). Compounds containing a coordination complex as part of the structure are called **coordination compounds**, and their chemistry is known as **coordination chemistry**. Although the older "hydrate" formulas are still used, the preferred method of writing the formula for coordination compounds places the metal atom or ion and the molecules or anions directly bonded to it within brackets to show that it is a single structural entity. Thus, the formula for the nickel(II)–ammonia compound is better written as $[Ni(NH_3)_6]Cl_2$.

All coordination complexes contain a metal atom or ion as the central part of the structure. Bonded to the metal are molecules or ions called **ligands** (from the Latin verb *ligare*, meaning "to bind"). In the preceding examples, water and ammonia are the ligands. The number of ligand atoms attached to the metal defines the **coordination number** of the metal. The geometry around the metal and described by the attached ligands is called the **coordination geometry**. In the nickel complex ion $[Ni(NH_3)_6]^{2+}$ (Figure 22.11), nickel has a coordination number of six and the six ligands are arranged in a regular octahedral geometry around the central metal ion.

Ligands can be either neutral molecules or anions (or, in rare instances, cations). The characteristic feature of a ligand is that it contains a lone pair of electrons. In the classic description of bonding in a coordination complex, the lone pair of electrons on a ligand is shared with the metal ion. The attachment is a coordinate covalent bond (◀ Section 8-5), because the electron pair being shared was originally on the ligand. The name "coordination complex" derives from the name given to this kind of bonding.

The net charge on a coordination complex is the sum of the charges on the metal and its attached groups. Complexes can be cations (as in the two nickel complexes used as examples here), anions, or uncharged.

Ligands such as H_2O and NH_3, which coordinate to the metal via a single Lewis base atom, are termed **monodentate**. The word "dentate" comes from the Latin *dentis*, meaning "tooth," so NH_3 is a "one-toothed" ligand. Some ligands attach to the metal with more than one donor atom. These ligands are called **polydentate**. Ethylenediamine (1,2-diaminoethane), $H_2NCH_2CH_2NH_2$, often abbreviated as en; oxalate ion, $C_2O_4^{2-}$ (ox^{2-}); and phenanthroline, $C_{12}H_8N_2$ (phen), are examples of **bidentate** ligands (Figure 22.12). Structures and examples of some complex ions with bidentate ligands are shown in Figure 22.13.

Polydentate ligands are also called **chelating ligands**, or just *chelates* (pronounced "key-lates"). The name derives from the Greek *chele*, meaning "claw." Because two or more bonds need to be broken to separate the ligand from the metal, complexes with chelated ligands often have greater stability than those with monodentate ligands. Complexes with chelating ligands are important in everyday life. One way to clean the rust out of water-cooled automobile engines and steam boilers

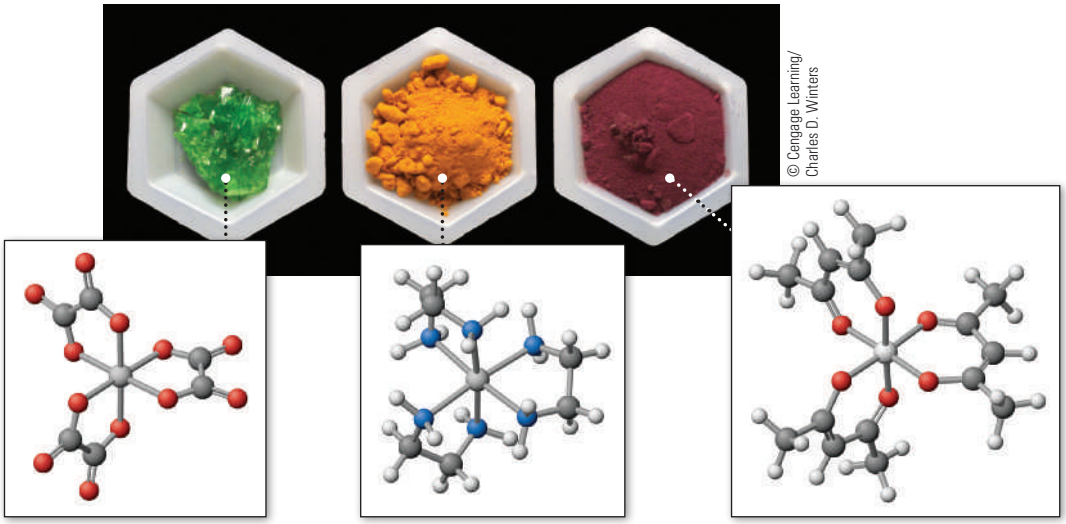

FIGURE 22.13 Complex ions with bidentate ligands. The three ligands shown are the oxalate anion ($C_2O_4^{2-}$), ethylenediamine (en), and the acetylacetonate anion (acac) (see Figure 22.12).

is to add a solution of oxalic acid. Iron(III) oxide reacts with oxalic acid to give a water-soluble iron oxalate complex ion:

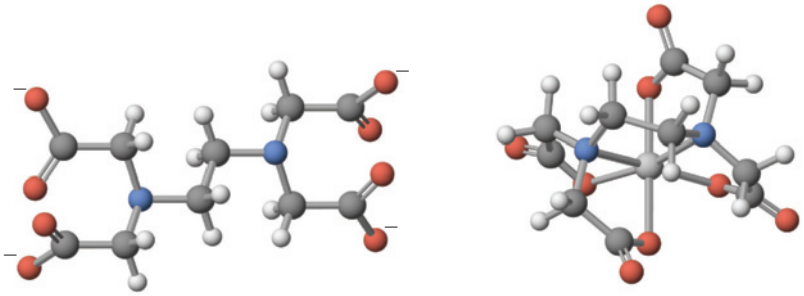
$$3\ H_2O(\ell) + Fe_2O_3(s) + 6\ H_2C_2O_4(aq) \longrightarrow 2\ [Fe(C_2O_4)_3]^{3-}(aq) + 6\ H_3O^+(aq)$$

Ethylenediaminetetraacetate ion ($EDTA^{4-}$), a hexadentate ligand, is an excellent chelating ligand (Figure 22.14). It can wrap around a metal ion, encapsulating it. Salts of this anion are often added to commercial salad dressings to remove traces of free metal ions from solution; otherwise, these metal ions can act as catalysts for the oxidation of the oils in the dressing. Without $EDTA^{4-}$, the dressing would quickly become rancid. Another use is in bathroom cleansers. The $EDTA^{4-}$ ion removes deposits of $CaCO_3$ and $MgCO_3$ left by hard water by coordinating to Ca^{2+} or Mg^{2+} to create soluble complex ions.

Complexes with polydentate ligands play particularly important roles in biochemistry, one example of which is described in *A Closer Look: Hemoglobin: A Molecule with a Tetradentate Ligand* (page 872).

Formulas of Coordination Compounds

It is useful to be able to predict the formula of a coordination complex, given the metal ion and ligands, and to derive the oxidation number of the coordinated metal ion, given the formula of a coordination compound. The following examples explore these issues.



(a) ethylenediaminetetraacetate, $EDTA^{4-}$ **(b)** $[Co(EDTA)]^-$

FIGURE 22.14 $EDTA^{4-}$, a hexadentate ligand. (a) Ethylenediaminetetraacetate, $EDTA^{4-}$. **(b)** $[Co(EDTA)]^-$. Notice the five-member rings created when this ligand bonds to the metal.

A CLOSER LOOK

Hemoglobin: A Molecule with a Tetradentate Ligand

Metal-containing coordination compounds figure prominently in many biochemical reactions. Perhaps the best-known example is hemoglobin, the molecule responsible for O_2 transport in the blood. It is also one of the most thoroughly studied bioinorganic compounds.

Hemoglobin (Hb) is a large iron-containing protein. It includes four polypeptide segments, each containing an iron(II) ion locked inside a porphyrin ring system and coordinated to a nitrogen atom from another part of the protein. A sixth site is available to attach to oxygen.

Hemoglobin functions by reversibly adding oxygen to the sixth coordination position of each iron, giving a complex called *oxyhemoglobin*.

Because hemoglobin features four iron centers, a maximum of four molecules of oxygen can bind to the molecule. The binding to oxygen is cooperative; that is, binding one O_2 molecule enhances the tendency to bind the second, third, and fourth O_2 molecules. Formation of the oxygenated complex is favored, but not too highly, because oxygen must also be released by the molecule to body tissues. Interestingly, an increase in acidity leads to a decrease in the stability of the oxygenated complex. This phenomenon is known as the *Bohr effect*, named for Christian Bohr, the father of Niels Bohr (Section 6-3). Release of oxygen in tissues is facilitated by an increase in acidity that results from the presence of CO_2 formed by metabolism.

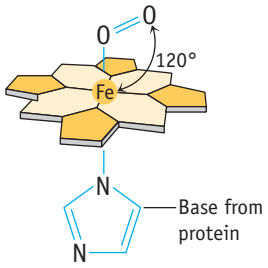

FIGURE Oxygen binding. Oxygen binds to the iron of the heme group in oxyhemoglobin (and in myoglobin). Interestingly, the Fe—O—O angle is bent.

Among the properties of hemoglobin is its ability to form a complex with carbon monoxide. This complex is very stable, with the equilibrium constant for the following reaction being about 200 (where Hb is hemoglobin):

$$HbO_2(aq) + CO(g) \rightleftharpoons HbCO(aq) + O_2(g)$$

When CO complexes with iron, the oxygen-carrying capacity of hemoglobin is lost. Consequently, CO (and the isoelectronic CN^- ion) is highly toxic to humans. Exposure to even small amounts greatly reduces the capacity of the blood to transport oxygen.

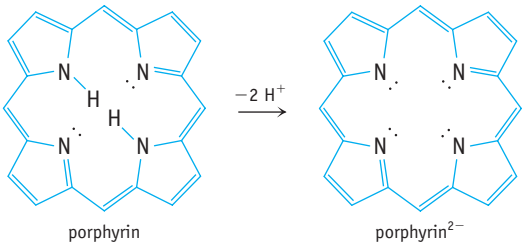

FIGURE Porphyrin ring of the heme group. The tetradentate ligand surrounding the iron(II) ion in hemoglobin is a dianion of a molecule called a *porphyrin*. Because of the double bonds in this structure, all of the carbon and nitrogen atoms in the dianion of the porphyrin lie in a plane. In addition, the nitrogen lone pairs are directed toward the center of the ion, and the molecular dimensions are such that a metal ion may fit nicely into the cavity.

EXAMPLE 22.1

Formulas of Coordination Complexes

Problem Give the formulas of the following coordination complexes:

(a) A Ni^{2+} ion is bound to two water molecules and two bidentate oxalate ions.

(b) A Co^{3+} ion is bound to one Cl^- ion, one ammonia molecule, and two bidentate ethylenediamine (en) molecules.

What Do You Know? The composition of the coordination complex is given for each part of the question.

Strategy The problem requires determining the net charge, which equals the sum of the charges of the various component parts of the complex ion. With that information, the metal and ligands can be assembled in the formula, which is placed in brackets, and the net charge indicated.

Solution

(a) This complex ion is constructed from two neutral H_2O molecules, two $C_2O_4^{2-}$ ions, and one Ni^{2+} ion, so the net charge on the complex is 2−. The formula for the complex ion is

$$[Ni(C_2O_4)_2(H_2O)_2]^{2-}$$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) This cobalt(III) complex ion combines two en molecules and one NH_3 molecule, none having a charge, as well as one Cl^- ion and a Co^{3+} ion. Thus, the net charge is 2+. The formula for this complex (writing out the entire formula for ethylenediamine) is

$$[Co(H_2NCH_2CH_2NH_2)_2(NH_3)Cl]^{2+}$$

Think about Your Answer Enclosing the formula of a complex in brackets is done to designate that this is a single unit. Species outside the brackets are counterions (when shown).

Check Your Understanding

(a) What is the formula of a complex ion composed of one Co^{3+} ion, three ammonia molecules, and three Cl^- ions?

(b) What is the formula for the coordination complex of an Fe^{2+} ion having two ethylenediamine ligands and two bromide ion ligands?

EXAMPLE 22.2

Coordination Compounds

Problem In each of the following coordination complexes, determine the metal's oxidation number and coordination number.

(a) $[Co(en)_2(NO_2)_2]Cl$

(b) $Pt(NH_3)_2(C_2O_4)$

(c) $Pt(NH_3)_2Cl_4$

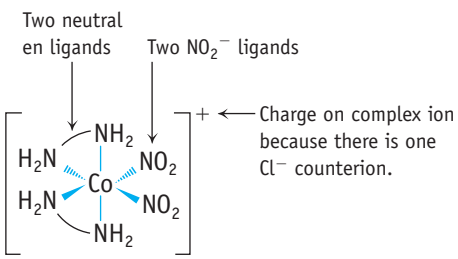
(d) $[Co(NH_3)_5Cl]SO_4$

What Do You Know? The oxidation number is the charge that must be present on the metal ion. The coordination number is the number of ligand attachments to the metal. Remember that bidentate ligands coordinate to two adjacent positions.

Strategy Each formula consists of a complex ion or molecule made up of the metal ion, neutral, and anionic ligands. Counterions (shown outside the square brackets) may also be present. The oxidation number of the metal is the charge necessary to balance the sum of the negative charges associated with any anionic ligands and counterions. The coordination number is the number of donor atoms in the ligands that are bonded to the metal. Remember that the bidentate ligands in these examples (en, oxalate ion) attach to the metal at two sites and that any counterions present are not part of the complex ion—that is, they are not ligands.

Solution

(a)

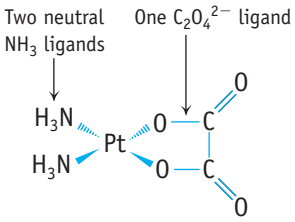


The central cobalt ion has a 3+ charge and the coordination number is 6.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

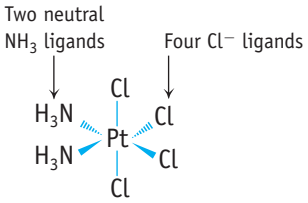
Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b)



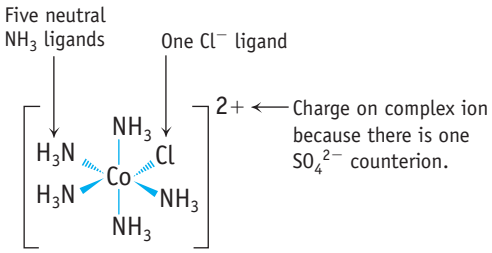
The central platinum ion has a 2+ charge and the coordination number is 4.

(c)



The central platinum ion has a 4+ charge and the coordination number is 6.

(d)



The central cobalt ion has a 3+ charge and the coordination number is 6.

Think about Your Answer Knowing the oxidation state of the metal in a coordination compound is important. From this, you can determine the electron configuration of the metal. As we shall see in Section 22-5, this information will be needed to determine important properties of a complex such as magnetism and color.

Check Your Understanding

(a) Determine the metal's oxidation number and coordination number in (i) $K_3[Co(NO_2)_6]$ and in (ii) $Mn(NH_3)_4Cl_2$.

(b) Determine the oxidation number and coordination number of cobalt in the complex $NH_4[Co(EDTA)]$.

Common Monodentate Ligands and Their Names

Ligand	Name
F^-	fluoro
Cl^-	chloro
Br^-	bromo
I^-	iodo
H_2O	aqua
NH_3	ammine
CO	carbonyl
CN^-	cyano
OH^-	hydroxo
$—NO_2^-$	nitro

Naming Coordination Compounds

Coordination compounds are named according to an established system. The three compounds below are named according to the rules that follow.

COMPOUND	SYSTEMATIC NAME
$[Ni(H_2O)_6]SO_4$	Hexaaquanickel(II) sulfate
$[Cr(en)_2(CN)_2]Cl$	Dicyanobis(ethylenediamine)chromium(III) chloride
$K[Pt(NH_3)Cl_3]$	Potassium amminetrichloroplatinate(II)

1. In naming a coordination compound that is a salt, name the cation first and then the anion. (This is how all salts are commonly named.)

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

2. When giving the name of the complex ion or molecule, name the ligands first, in alphabetical order, followed by the name of the metal. (When determining alphabetical order of the ligands, ignore any prefix.)
3. Ligands and their names:
   (a) If a ligand is an anion whose name ends in *-ite* or *-ate*, the final *e* is changed to *o* (sulfate ⟶ sulfato or nitrite ⟶ nitrito).
   (b) If the ligand is an anion whose name ends in *-ide*, the ending is changed to *o* (chloride ⟶ chloro, cyanide ⟶ cyano).
   (c) If the ligand is a neutral molecule, its common name is usually used with several important exceptions: Water as a ligand is referred to as *aqua;* ammonia is called *ammine;* and CO is called *carbonyl*.
   (d) When there is more than one of a particular monodentate ligand with a simple name, the number of ligands is designated by the appropriate prefix: *di*, *tri*, *tetra*, *penta*, or *hexa*. If the ligand name is complicated, the prefix changes to *bis*, *tris*, *tetrakis*, *pentakis*, or *hexakis*, followed by the ligand name in parentheses.
4. If the coordination complex is an anion, the suffix *-ate* is added to the metal name.
5. Following the name of the metal, the oxidation number of the metal is given in Roman numerals.

EXAMPLE 22.3

Naming Coordination Compounds

Problem Name the following compounds:

(a) $[Cu(NH_3)_4]SO_4$

(b) $K_2[CoCl_4]$

(c) $Co(phen)_2Cl_2$

(d) $[Co(en)_2(H_2O)Cl]Cl_2$

What Do You Know? The formula of each compound is given.

Strategy Apply the rules for nomenclature given above.

Solution

(a) The complex ion (in square brackets) is composed of four NH_3 molecules (named *ammine* in a complex) and the copper ion. To balance the 2− charge on the sulfate counterion and account for four NH_3 ligands with no charge, copper must have a 2+ charge. The compound's name is

tetraamminecopper(II) sulfate

(b) The complex ion $[CoCl_4]^{2-}$ has a 2− charge to balance two K^+ counterions. With four Cl^- ligands, the cobalt ion must have a 2+ charge, so the sum of charges is 2−. The name of the compound is

potassium tetrachlorocobaltate(II)

(c) This is a neutral coordination compound. The ligands include two Cl^- ions and two neutral bidentate *phen* (phenanthroline) ligands (page 870). The metal ion must therefore have a 2+ charge (Co^{2+}). The name, listing ligands in alphabetical order, is

dichlorobis(phenanthroline)cobalt(II)

(d) The complex ion has a 2+ charge because it is paired with two uncoordinated Cl^- ions. The cobalt ion is Co^{3+} because it is bonded to two neutral en ligands, one neutral water, and one Cl^-. The name is

aquachlorobis(ethylenediamine)cobalt(III) chloride

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Think about Your Answer The earliest studies of coordination compounds created a colorful array of names, and a few of these are still used (Prussian Blue, mentioned earlier, and Zeise's salt, $K[Pt(C_2H_4)Cl_3]$, are two examples). However, as the depth and breadth of coordination chemistry expands, a systematic nomenclature is essential to communication among scientists working in the area. The rules of nomenclature make it possible for any scientist to derive a formula from the name, or to name a compound given its formula.

Check Your Understanding

Name the following coordination compounds.

(a) $[Ni(H_2O)_6]SO_4$ (b) $[Cr(en)_2(CN)_2]Cl$ (c) $K[Pt(NH_3)Cl_3]$ (d) $K[CuCl_2]$

REVIEW & CHECK FOR SECTION 22-3

1. What is the coordination number for the metal in the compound tetraaquaoxalatoiron(III) chloride?

   (a) 4 (b) 6 (c) 7 (d) 2

2. What is the oxidation number of the metal in $(NH_4)_3[Fe(CN)_6]$?

   (a) 0 (b) +1 (c) +2 (d) +3

3. Which of the following is a complex ion based on an iron(II) ion?

   (a) $[Fe(H_2O)_4Cl_2]ClO_4$ (c) $Fe(acac)_3$

   (b) $Na_4[Fe(C_2O_4)_3]$ (d) $[Fe(NH_3)_5Cl]SO_4$

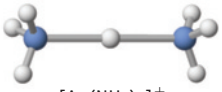
4. In which of the following complexes is the metal 6-coordinate?

   (a) lithium tetrachlorocobaltate(II)

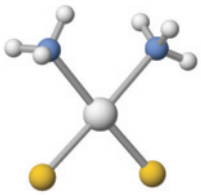
   (b) pentaamminehydroxochromium(III) chloride

   (c) bis(ethylenediamine)silver(I) chloride

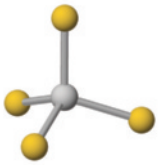
   (d) diamminedichlorozinc(II)



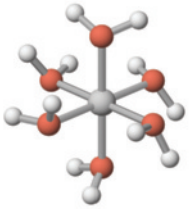
$[Ag(NH_3)_2]^+$



$Pt(NH_3)_2Cl_2$



$[NiCl_4]^{2-}$



$[Ni(H_2O)_6]^{2+}$

Common Coordination Geometries

22-4 Structures of Coordination Compounds

Common Coordination Geometries

The geometry of a coordination complex is defined by the arrangement of donor atoms of the ligands around the central metal ion. Metal ions in coordination compounds can have coordination numbers ranging from 2 to 12. Only complexes with coordination numbers of 2, 4, and 6 are common, however, so we will concentrate on species such as $[ML_2]^{n\pm}$, $[ML_4]^{n\pm}$, and $[ML_6]^{n\pm}$, where M is the metal ion and L is a *monodentate* ligand. For complexes having these stoichiometries, the following geometries are encountered:

- All $[ML_2]^{n\pm}$ complexes are linear. The two ligands are on opposite sides of the metal, and the L—M—L bond angle is 180°. Common examples include $[Ag(NH_3)_2]^+$ and $[CuCl_2]^-$.
- Tetrahedral geometry occurs in many $[ML_4]^{n\pm}$ complexes. Examples include $TiCl_4$, $[CoCl_4]^{2-}$, $[NiCl_4]^{2-}$, and $[Zn(NH_3)_4]^{2+}$.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Some $[ML_4]^{n\pm}$ complexes have square planar geometry. It is most often found for metal ions that have eight *d* electrons. Examples include $Pt(NH_3)_2Cl_2$, $[Ni(CN)_4]^{2-}$, and the nickel complex with the dimethylglyoximate (dmg^-) ligand in Figure 22.10.
- Octahedral geometry is found in complexes with the stoichiometry $[ML_6]^{n\pm}$ (Figure 22.10).

Isomerism

Isomers are compounds with the same molecular formulas but different arrangements of atoms. There are several forms of isomerism and some are key to the chemical behavior of the compounds.

- *Structural isomers* have the same molecular formula but different bonding arrangements of atoms.
- *Stereoisomers* have the same atom-to-atom bonding sequence, but the atoms differ in their arrangement in space. There are two types of stereoisomerism: *geometric isomerism* and *optical isomerism*.

All three types of isomerism—structural, geometric, and optical—are encountered in coordination chemistry.

Structural Isomerism

The two most important types of structural isomerism in coordination chemistry are coordination isomerism and linkage isomerism. **Coordination isomerism** occurs when it is possible to exchange a coordinated ligand and the uncoordinated counterion. For example, dark violet $[Co(NH_3)_5Br]SO_4$ and red $[Co(NH_3)_5SO_4]Br$ are coordination isomers. In the first compound, bromide ion is a ligand and sulfate is a counterion; in the second, sulfate is a ligand and bromide is the counterion. A diagnostic test for this kind of isomer is often made based on chemical reactions. For example, these two compounds can be distinguished by precipitation reactions. Addition of $Ba^{2+}(aq)$ to a solution of $[Co(NH_3)_5Br]SO_4$ gives a precipitate of $BaSO_4$, indicating the presence of sulfate ion in solution. In contrast, no reaction occurs if $Ba^{2+}(aq)$ is added to a solution of $[Co(NH_3)_5SO_4]Br$. In this complex, sulfate ion is attached to Co^{3+} and is not a free ion in solution.

$$[Co(NH_3)_5Br]SO_4 + Ba^{2+}(aq) \longrightarrow BaSO_4(s) + [Co(NH_3)_5Br]^{2+}(aq)$$

$$[Co(NH_3)_5SO_4]Br + Ba^{2+}(aq) \longrightarrow \text{no reaction}$$

Linkage isomerism occurs when it is possible to attach a ligand to the metal through different atoms. The two most common ligands with which linkage isomerism arises are thiocyanate, SCN^-, and nitrite, NO_2^-. The Lewis structure of the thiocyanate ion shows that there are lone pairs of electrons on sulfur and nitrogen. The ligand can attach to a metal either through sulfur (called *S-bonded thiocyanate)* or through nitrogen (called *N-bonded thiocyanate*). Nitrite ion can attach either at oxygen or at nitrogen. The former are called nitrito complexes; the latter are nitro complexes (Figure 22.15).

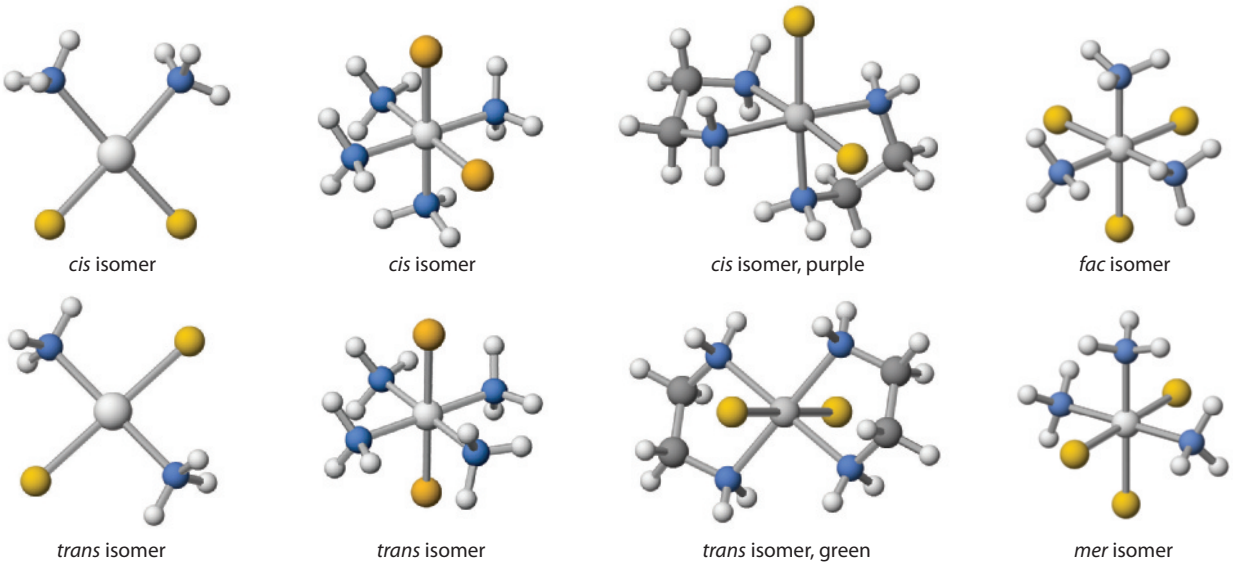
FIGURE 22.15 Linkage isomers, $[Co(NH_3)_5ONO]^{2+}$ and $[Co(NH_3)_5NO_2]^{2+}$. These complex ions, whose systematic names are pentaamminenitritocobalt(III) and pentaamminenitrocobalt(III), respectively, were the first known examples of this type of isomerism. (The compounds shown in this figure have two chloride ions as counterions.)

Geometric Isomerism

***Cis–Trans* Isomerism** *Cis–trans* isomerism is not possible for tetrahedral complexes. All L—M—L angles are 109.5°, and all positions are equivalent in this three-dimensional structure.

Geometric isomerism results when the atoms bonded directly to the metal have a different spatial arrangement. The simplest example of geometric isomerism in coordination chemistry is *cis–trans* isomerism, which occurs in both square-planar and octahedral complexes. An example of *cis–trans* isomerism is seen in the square-planar complex $Pt(NH_3)_2Cl_2$ (Figure 22.16a). In this complex, the two Cl^- ions can be either adjacent to each other (*cis*) or on opposite sides of the metal (*trans*). The *cis* isomer is effective in the treatment of testicular, ovarian, bladder, and osteogenic sarcoma cancers, but the *trans* isomer has no effect on these diseases.

Cis–trans isomerism occurs in octahedral complexes with the formula MA_4B_2. In the complex $[Co(NH_3)_4Cl_2]^+$ the two Cl^- ions can occupy positions that are either adjacent (Cl—Co—Cl angle = 90°) or on opposite sides of the metal (Cl—Co—Cl angle = 180°) (Figure 22.16b).



(a) The square-planar complex $Pt(NH_3)_2Cl_2$ can exist in two geometries, *cis* and *trans*.

(b) *Cis* and *trans* octahedral isomers for $[Co(NH_3)_4Cl_2]^+$.

(c) *Cis* and *trans* octahedral isomers for $[Co(en)_2Cl_2]^+$.

(d) *Fac* and *mer* isomers of $Cr(NH_3)_3Cl_3$: *fac* isomer, the three identical ligands are arranged at the corners of a triangular face. In the *mer* isomer, the three similar ligands follow a meridian.

FIGURE 22.16 Geometric isomers.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Cis–trans isomerism in an octahedral complex with two bidentate ethylenediamine ligands is illustrated by $[Co(H_2NCH_2CH_2NH_2)_2Cl_2]^+$. The two Cl^- ions occupy positions that are either adjacent (the purple *cis* isomer) or opposite (the green *trans* isomer) (Figure 22.16c).

Another common type of geometric isomerism occurs for octahedral complexes with the general formula MA_3B_3. A *fac* isomer has three identical ligands lying at the corners of a triangular face of an octahedron defined by the ligands (*fac* = facial), whereas the ligands follow a meridian in the *mer* isomer (*mer* = meridional). *Fac* and *mer* isomers of $Cr(NH_3)_3Cl_3$ are shown in Figure 22.16d.

Optical Isomerism

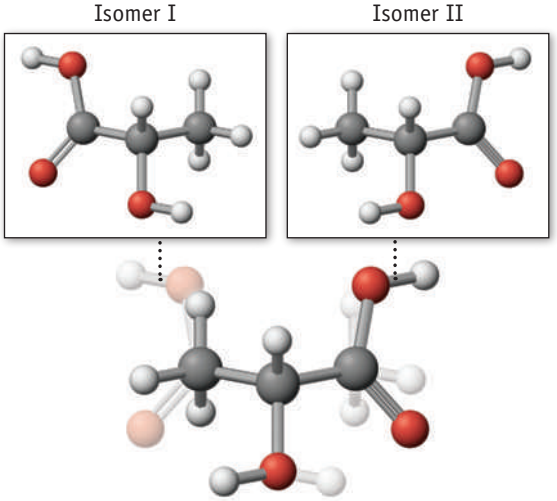
Optical isomerism is a second type of stereoisomerism. Optical isomers are molecules that have nonsuperimposable mirror images. Molecules that have nonsuperimposable mirror images are termed **chiral**. Pairs of nonsuperimposable, mirror-image molecules are called **enantiomers**.

In chemistry the usual model for chirality is a carbon-based compound with four different groups attached to the C atom (Figure 22.17). One enantiomer is a mirror image of the other, and one cannot be superimposed on the other. (Chirality occurs widely in organic and biochemistry chemistry and will be discussed in Chapters 23 and 24.)

There are many examples of chirality in non-chemical contexts. Seashells, for example, may spiral in different directions, giving left-handed and right-handed shells (Figure 22.17). Bolts and screws can also have left-handed or right-handed threads. Although they appear similar, they cannot be interchanged in use.

Pure samples of enantiomers have the same physical properties, such as melting point, boiling point, density, and solubility in common solvents, but they differ in a significant way: When a beam of plane-polarized light passes through a solution of a pure enantiomer, the plane of polarization rotates (Figure 22.18). The two enantiomers rotate polarized light to an equal extent, but do so in opposite directions. The term optical isomerism is used because this effect involves light.

Optical isomerism (chirality) occurs for octahedral complexes when the metal ion coordinates to three bidentate ligands or when the metal ion coordinates to two bidentate ligands and two monodentate ligands in a *cis* position. The complexes $[Co(en)_3]^{3+}$ and *cis*-$[Co(en)_2Cl_2]^+$, illustrated in Figure 22.19, are examples of chiral



Lactic acid enantiomers are nonsuperimposable, just as your right hand is not superimposable on your left.

Steven Hyatt

Left- and right-handed seashells (of different species)

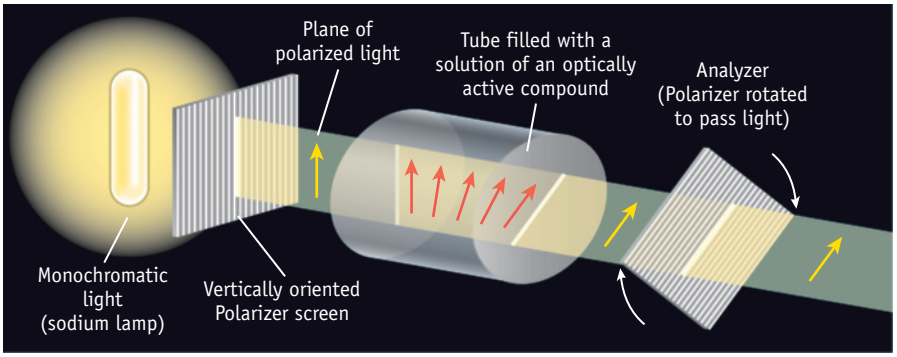

FIGURE 22.18 Rotation of plane polarized light by an optical isomer. Monochromatic light (light of only one wavelength) is produced by a sodium lamp. After it passes through a polarizing filter, the light vibrates in only one direction—it is polarized. A solution of an optical isomer placed between the first and second polarizing filters causes rotation of the plane of polarized light. The second filter is rotated to a point where a maximum of light is transmitted and the angle of rotation is calculated. The magnitude and direction of rotation are unique physical properties of the optical isomer being tested.

complexes. The diagnostic test for chirality is met with both species: Mirror images of these molecules are not superimposable on one another, and solutions of the optical isomers rotate plane-polarized light in opposite directions.

EXAMPLE 22.4

Isomerism in Coordination Chemistry

Problem For which of the following compounds or complex ions do isomers exist? If isomers are possible, identify the type of isomerism (structural, geometric, or optical).

(a) $[Co(NH_3)_4Cl_2]^+$

(b) $Pt(NH_3)_2(CN)_2$ (square-planar)

(c) $Co(NH_3)_3Cl_3$

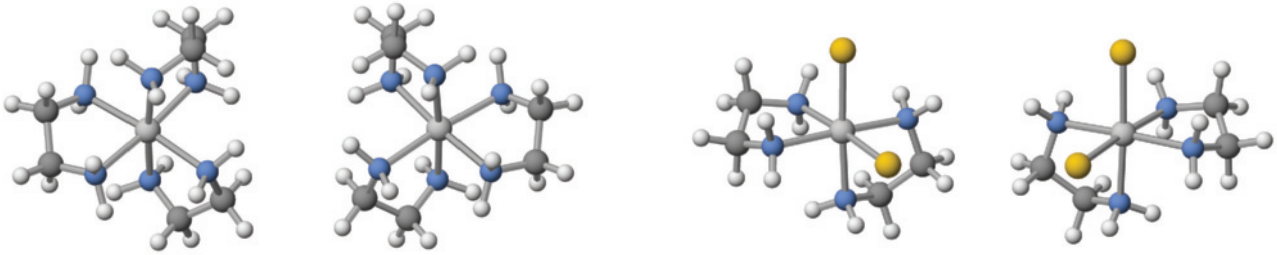
(d) $K_3[Fe(C_2O_4)_3]$

(e) $Zn(NH_3)_2Cl_2$ (tetrahedral)

(f) $[Co(NH_3)_5SCN]^{2+}$

What Do You Know? You can infer coordination number and geometry from the formulas. Structural isomers are those for which there are different attachments of atoms; geometric isomers are those in which the spatial arrangement of atoms is different. Complexes that are optically active have nonsuperimposable mirror images.

Strategy Determine the number of ligands attached to the metal and decide whether the ligands are monodentate or bidentate. Knowing how many donor atoms are coordinated



$[Co(en)_3]^{3+}$ $[Co(en)_3]^{3+}$ mirror image *cis*-$[Co(en)_2Cl_2]^+$ *cis*-$[Co(en)_2Cl_2]^+$ mirror image

FIGURE 22.19 Chiral metal complexes. Both $[Co(en)_3]^{3+}$ and *cis*-$[Co(en)_2Cl_2]^+$ are chiral. Notice that the image of a compound is not superimposable on its mirror image.

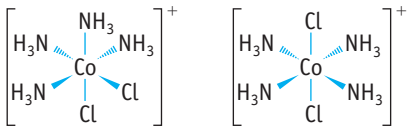
to the metal (the coordination number) will allow you to establish the metal geometry. The only stereoisomerism possible for square-planar complexes is geometric (*cis* and *trans*). Tetrahedral coordination complexes do not have geometric or optical isomers. Six-coordinate complexes of the formula MA_4B_2 can be either *cis* or *trans*. *Mer* and *fac* isomers are possible with a stoichiometry of MA_3B_3. Optical activity arises for metal complexes of the formula *cis*-M(bidentate)$_2X_2$ and M(bidentate)$_3$. Drawing pictures of the molecules will help you visualize the isomers.

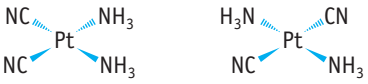
Solution

(a) Two geometric isomers can be drawn for octahedral complexes with a formula of MA_4B_2. One isomer has two Cl^- ions in *cis* positions (adjacent positions, at a 90° angle), and the other isomer has the Cl^- ligands in *trans* positions (with a 180° angle between the ligands). Optical isomers are not possible.



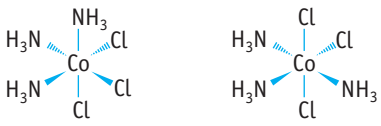
cis isomer *trans* isomer

(b) In this square-planar complex, the two NH_3 ligands (and the two CN^- ligands) can be either *cis* or *trans*. These are geometric isomers. Optical isomers are not possible.



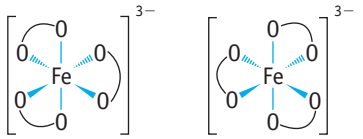
cis isomer *trans* isomer

(c) Two geometric isomers of this octahedral complex, with chloride ligands either *fac* or *mer*, are possible. In the *fac* isomer, the three Cl^- ligands are all at 90° to each other; in the *mer* isomer, two Cl^- ligands are at 180°, and the third is 90° from the other two. Optical isomers are not possible.



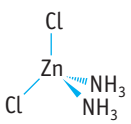
fac isomer *mer* isomer

(d) Ignore the counterions, K^+. The anion is an octahedral complex. Remember that the bidentate oxalate ion occupies two adjacent coordination sites of the metal, and that three oxalate ligands means that the metal has a coordination number of 6. Mirror images of complexes of the stoichiometry M(bidentate)$_3$ are not superimposable; therefore, two optical isomers are possible. (Here the ligands, $C_2O_4^{2-}$, are drawn abbreviated as O—O.)



nonsuperimposable mirror images of $[Fe(ox)_3]^{3-}$

(e) Only a single structure is possible for tetrahedral complexes such as $Zn(NH_3)_2Cl_2$.



Optical Isomerism Square-planar complexes are incapable of optical isomerism based at the metal center; mirror images are always superimposable. Chiral tetrahedral complexes are possible, but examples of complexes with a metal bonded tetrahedrally to four different monodentate ligands are extremely rare.

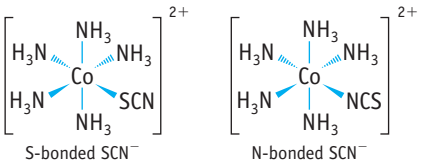
(f) Only linkage isomerism (structural isomerism) is possible for this octahedral cobalt complex. Either the sulfur or the nitrogen of the SCN^- anion can be attached to the cobalt(III) ion in this complex.



Think about Your Answer More complex situations occur when a complex has three or more different ligands. In those instances it is important to be able to visualize the three-dimensional molecule and to organize your approach.

Check Your Understanding

What types of isomers are possible for the following compounds or complex ions?

(a) $K[Co(NH_3)_2Cl_4]$

(b) $Pt(en)Cl_2$ (square-planar)

(c) $[Co(NH_3)_5Cl]^{2+}$

(d) $[Ru(phen)_3]Cl_3$

(e) $Na_2[MnCl_4]$ (tetrahedral)

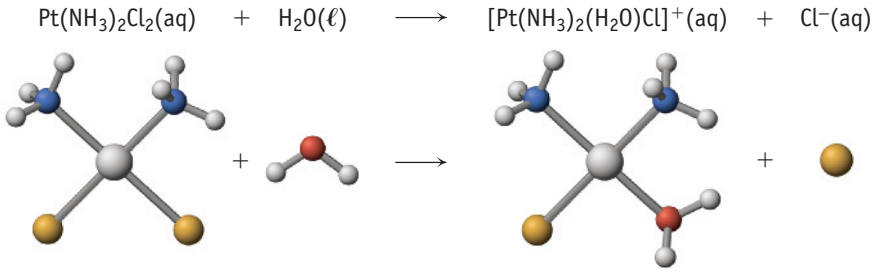
(f) $[Co(NH_3)_5NO_2]^{2+}$

CASE STUDY *Cisplatin:* Accidental Discovery of a Chemotherapy Agent

There are many naturally occurring metal-based molecules such as heme, vitamin B_{12}, and the enzyme involved in fixing nitrogen (nitrogenase). Chemists have also synthesized various metal-based compounds for medical purposes. One of these, cisplatin $[PtCl_2(NH_3)_2]$, was known for many years, but it was discovered serendipitously to be effective in treatment of certain kinds of cancers.

In 1965, Barnett Rosenberg, a biophysicist at Michigan State University, set out to study the effect of electric fields on living cells, but the results of his experiments were very different from his expectations. He and his students had placed an aqueous suspension of live *Escherichia coli* bacteria in an electric field between supposedly inert platinum electrodes. Much to their surprise, they found that cell growth was significantly affected. After careful experimentation, the effect on cell division was found to be due to a trace of a complex of platinum, ammonia, and chloride ion formed by an electrolytic process involving the platinum electrode in the presence of ammonia in the growth medium.

To follow up on this interesting discovery, Rosenberg and his students tested the effect of *cis*- and *trans*-$PtCl_2(NH_3)_2$ on cell growth and found that only the *cis* isomer was effective. This led Rosenberg and others to study the effect of so-called cisplatin on cancer cell growth, and the result is that *cisplatin* and similar compounds are now used to treat genitourinary tumors. In fact, testicular cancer in particular is now considered largely curable because of cisplatin chemotherapy.



The chemistry of cisplatin has now been thoroughly studied and illustrates many of the principles of transition metal coordination chemistry. It has been found that *cisplatin* has a half-life of 2.5 hours for the replacement of a Cl^- ligand by water at 310 K (in a first-order reaction) and that the replacement of a second Cl^- ligand by water is slightly faster.

The aqua species are acidic and damaging to the kidneys, so cisplatin is generally used in a saline solution to prevent the hydrolysis reactions. It has been found that, in blood plasma at pH 7.4 and with a Cl^- ion concentration of about 1.04×10^{-5} M, $PtCl_2(NH_3)_2$ and $PtCl(OH)(NH_3)_2$ are the dominant species. In the cell nucleus, however, the Cl^- ion concentration is lower, and the aqua species are present in higher concentration.

Question:

If a patient is given 10.0 mg of cisplatin, what quantity remains as cisplatin at 24 hours?

The answer to this question is available in Appendix N.

REVIEW & CHECK FOR SECTION 22-4

1. Which of the following complexes cannot exist as *cis–trans* isomers?

   (a) $Fe(NH_3)_4Cl_2$ (c) Square-planar $[PtCl_2(CN)_2]^{2-}$

   (b) $Ni(H_2O)_4(C_2O_4)$ ($C_2O_4^{2-}$ = oxalate) (d) $Mn(en)_2Cl_2$ (en = ethylenediamine)

2. Which of the following complexes can exist as optical isomers?

   (a) Square-planar $Pt(NH_3)(H_2O)(CN)Cl$ (c) $Fe(NH_3)_4Cl_2$

   (b) $Fe(en)_2(CN)_2$ (en = ethylenediamine) (d) $Cr(NH_3)_3Cl_3$

3. Which statement best describes the isomers for the complex $Fe(en)_2Cl_2$? (en = ethylenediamine)

   (a) Only a single structure can be drawn.

   (b) There are two geometric isomers, one of which has an optical isomer.

   (c) The compound exists as a pair of optical isomers.

   (d) This compound exists as two structural isomers.

4. How many geometric isomers are possible for $Fe(en)(NH_3)_2Cl_2$? (To answer this question, try to draw out possible structures in an organized manner. Start by placing the bidentate ethylenediamine ligand in two coordination sites, then add chloride and ammonia ligands into the remaining positions in various ways.)

22-5 Bonding in Coordination Compounds

Metal–ligand bonding in a coordination complex was described earlier in this chapter as being covalent, resulting from the sharing of an electron pair between the metal and the ligand donor atom. Although frequently used, this description is not capable of explaining the color and magnetic behavior of these complexes. As a consequence, the covalent bonding picture has now largely been superseded by two other bonding models: molecular orbital theory and ligand field theory.

The bonding model based on molecular orbital theory assumes that the metal and the ligand bond through the molecular orbitals formed by atomic orbital overlap between metal and ligand. The **ligand field model**, in contrast, focuses on repulsion (and destabilization) of electrons in the metal coordination sphere. The ligand field model also assumes that the positive metal ion and the negative ligand lone pair are attracted electrostatically; that is, the bond results from the attraction between a positively charged metal ion and a negative ion or the negative end of a polar molecule. For the most part, the molecular orbital and ligand field models predict similar, qualitative results regarding color and magnetic behavior. Here, we will focus on the ligand field approach and illustrate how it explains color and magnetism of transition metal complexes.

The *d* Orbitals: Ligand Field Theory

To understand ligand field theory, it is necessary to look at the *d* orbitals, specifically with regard to their orientation relative to the positions of ligands in a metal complex.

In an isolated atom or ion, the five *d* orbitals have the same energy. For a metal atom or ion in a coordination complex, however, the *d* orbitals have different energies. According to the ligand field model, repulsion between *d* electrons on the metal and electron pairs of the ligands destabilizes electrons that reside in the *d* orbitals;

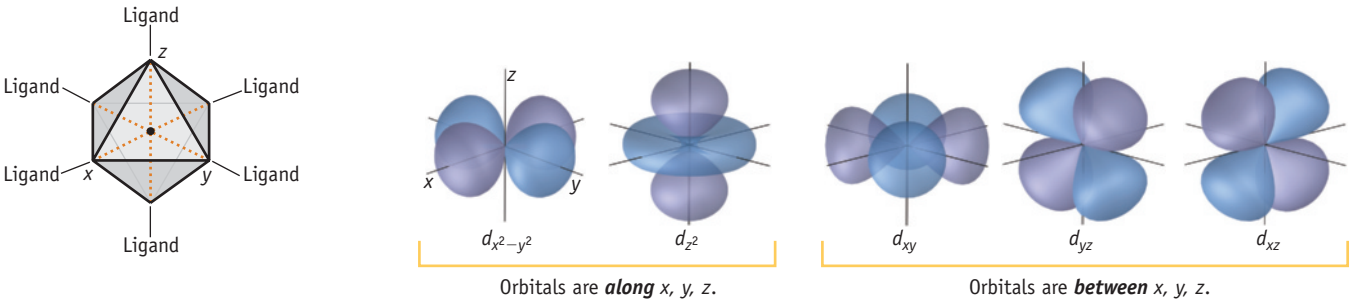

FIGURE 22.20 The *d* orbitals. The five *d* orbitals and their spatial relation to the ligands on the *x*-, *y*-, and *z*-axes.

that is, it causes their energy to increase. Electrons in the various *d* orbitals are not affected equally, however, because of their different orientations in space relative to the position of the ligand lone pairs.

We look first at octahedral complexes. Assume the ligands in an octahedral complex lie along the *x*-, *y*-, and *z*-axes. This results in the five *d* orbitals being subdivided into two sets: the $d_{x^2-y^2}$ and d_{z^2} orbitals in one set and the d_{xy}, d_{xz}, and d_{yz} orbitals in the second (Figure 22.20). The $d_{x^2-y^2}$ and d_{z^2} orbitals are directed along the *x*-, *y*-, and *z*-axes, whereas the orbitals of the second group are aligned between these axes. Electrons in the $d_{x^2-y^2}$ and d_{z^2} orbitals experience a larger repulsion because these orbitals point directly at the ligand electron pairs. A smaller repulsive effect is experienced by electrons in the d_{xy}, d_{xz}, and d_{yz} orbitals. The difference in degree of repulsion means that an energy difference exists between the two sets of orbitals in an octahedral complex (Figure 22.21). This difference, called the **ligand field splitting** and denoted by the symbol Δ_0, is a function of the metal and the ligands and varies predictably from one complex to another.

A different splitting pattern is encountered with square-planar complexes (Figure 22.22). Assume that the four ligands are along the *x*- and *y*-axes. The $d_{x^2-y^2}$ orbital also points along these axes, so it has the highest energy. The d_{xy} orbital (which also lies in the *xy*-plane, but does not point at the ligands) is next highest in energy, followed by the d_{z^2} orbital. The d_{xz} and d_{yz} orbitals, both of which partially point in the *z*-direction, have the lowest energy.

The *d*-orbital splitting pattern for a tetrahedral complex is the reverse of the pattern observed for octahedral complexes. Three orbitals (d_{xz}, d_{xy}, d_{yz}) are higher in energy, whereas the $d_{x^2-y^2}$ and d_{z^2} orbitals are below them in energy (Figure 22.22).

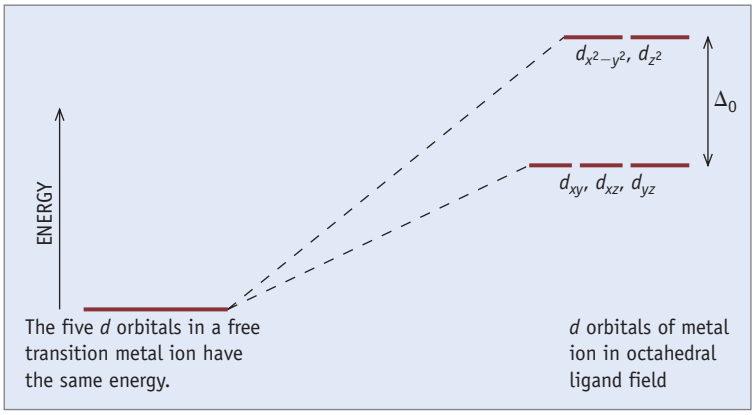

FIGURE 22.21 Ligand field splitting for an octahedral complex. The *d*-orbital energies increase as the ligands approach the metal along the *x*-, *y*-, and *z*-axes. The d_{xy}, d_{xz}, and d_{yz} orbitals, not pointed toward the ligands, are less destabilized than the $d_{x^2-y^2}$ and d_{z^2} orbitals. Thus, the d_{xy}, d_{xz}, and d_{yz} orbitals are at lower energy. (Δ_0 stands for the splitting in an octahedral ligand field.)

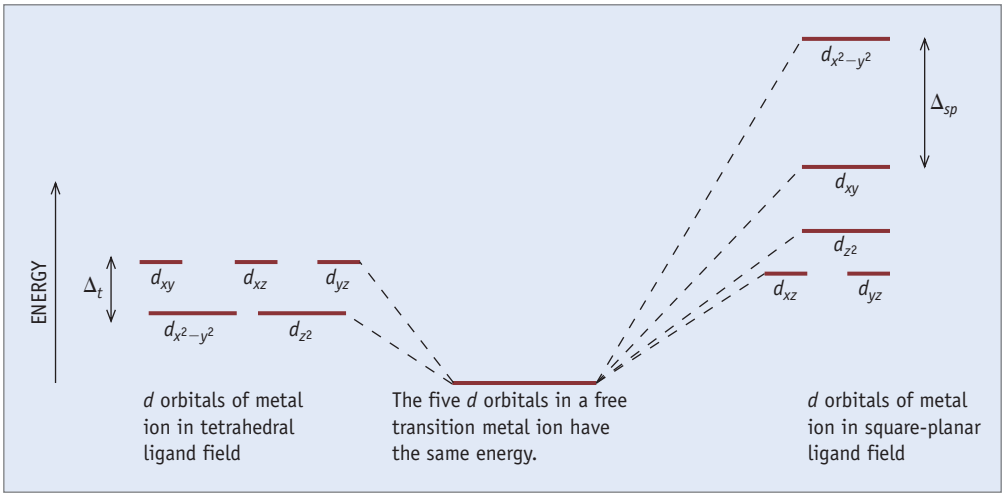

FIGURE 22.22 Splitting of the *d* orbitals in *(left)* tetrahedral and *(right)* square-planar geometries. (Δ_t and Δ_{sp} are, respectively, the splitting in tetrahedral and square-planar ligand fields.)

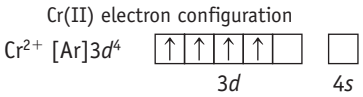
Electron Configurations and Magnetic Properties

The *d*-orbital splitting in coordination complexes provides an explanation of both the magnetic behavior and the color of these complexes. To understand this explanation, however, we must first understand how to assign electrons to the various orbitals in each geometry.

A gaseous Cr^{2+} ion has the electron configuration [Ar]$3d^4$. The term *gaseous* in this context is used to denote a single, isolated atom or ion with all other particles located an infinite distance away. In this situation, the five 3*d* orbitals have the same energy. The four electrons reside singly in different *d* orbitals, according to Hund's rule, and the Cr^{2+} ion has four unpaired electrons.



When the Cr^{2+} ion is part of an octahedral complex, the five *d* orbitals do not have identical energies. As illustrated in Figure 22.21, these orbitals divide into two sets, with the d_{xy}, d_{xz}, and d_{yz} orbitals having a lower energy than the $d_{x^2-y^2}$ and d_{z^2} orbitals. Having two sets of orbitals means that two different electron configurations are possible (Figure 22.23). Three of the four *d* electrons in Cr^{2+} are assigned

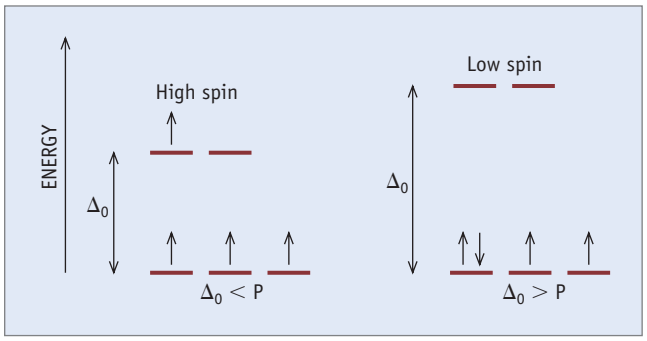


FIGURE 22.23 High- and low-spin cases for an octahedral chromium(II) complex. *(left, high spin)* If the ligand field splitting (Δ_0) is smaller than the pairing energy (P), the electrons are placed in different orbitals, and the complex has four unpaired electrons. *(right, low spin)* If the splitting is larger than the pairing energy, all four electrons will be in the lower-energy orbital set. This requires pairing two electrons in one of the orbitals, so the complex will have two unpaired electrons.

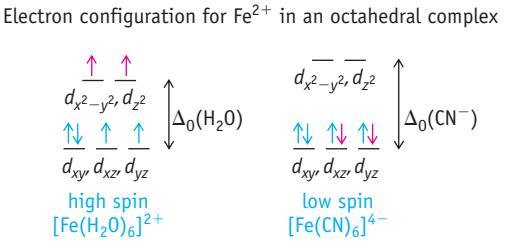
to the lower-energy d_{xy}, d_{xz}, and d_{yz} orbitals. The fourth electron either can be assigned to an orbital in the higher-energy $d_{x^2-y^2}$ and d_{z^2} set or can pair up with an electron already in the lower-energy set. The first arrangement is called **high spin**, because it has the maximum number of unpaired electrons, four in the case of Cr^{2+}. The second arrangement is called **low spin**, because it has the minimum number of unpaired electrons possible.

At first glance, a high-spin configuration appears to contradict conventional thinking. It seems logical that the most stable situation would occur when electrons occupy the lowest-energy orbitals. A second factor intervenes, however. Because electrons are negatively charged, repulsion increases when they are assigned to the same orbital. This destabilizing effect is due to the **pairing energy (P)**. The preference for an electron to be in the lowest-energy orbital and the pairing energy have opposing effects (Figure 22.23). Low-spin complexes arise when the splitting of the *d* orbitals by the ligand field is large—that is, when Δ_0 has a large value. The energy gained by putting all of the electrons in the lowest-energy level is the dominant effect when $\Delta_0 > P$. In contrast, high-spin complexes occur if the value of Δ_0 is smaller than the energy required to pair electrons ($\Delta_0 < P$).

For octahedral complexes, high- and low-spin complexes are possible only for configurations d^4 through d^7 (Figure 22.24). Complexes of the d^6 metal ion, Fe^{2+}, for example, can have either high spin or low spin. The complex formed when the Fe^{2+} ion is placed in water, $[Fe(H_2O)_6]^{2+}$, is high spin, whereas the $[Fe(CN)_6]^{4-}$ complex ion is low spin.



It is possible to tell whether a complex is high or low spin by examining its magnetic behavior. The high-spin complex $[Fe(H_2O)_6]^{2+}$ has four unpaired electrons and is *paramagnetic* (attracted by a magnet), whereas the low-spin $[Fe(CN)_6]^{4-}$ complex has no unpaired electrons and is *diamagnetic* (repelled by a magnet) (◀ Section 7-4).

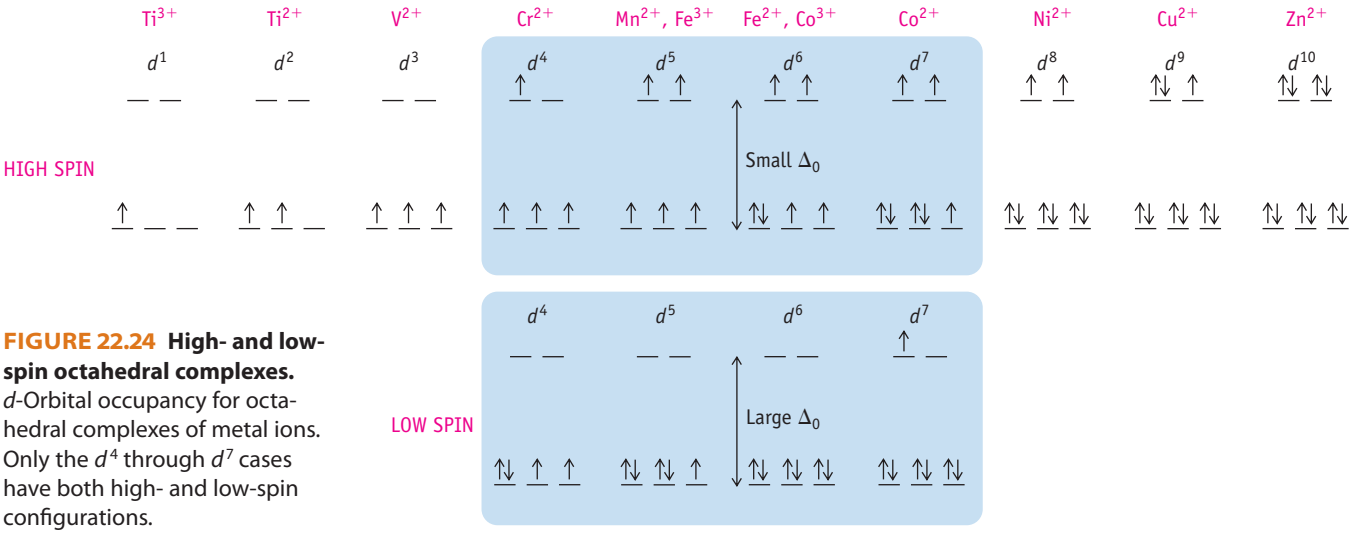


FIGURE 22.24 High- and low-spin octahedral complexes. *d*-Orbital occupancy for octahedral complexes of metal ions. Only the d^4 through d^7 cases have both high- and low-spin configurations.

PROBLEM SOLVING TIP 22.1

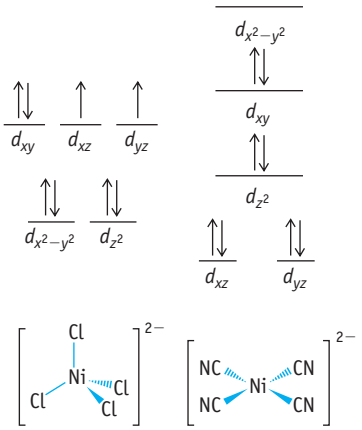
Ligand Field Theory

This summary of the concepts of ligand field theory may help you to keep the broader picture in mind.

- Ligand–metal bonding results from the electrostatic attraction between a metal cation and either an anion or a polar molecule.
- The ligands define a coordination geometry. Common geometries are linear (coordination number = 2), tetrahedral and square-planar (coordination number = 4), and octahedral (coordination number = 6).
- The placement of the ligands around the metal causes the *d* orbitals on the metal to have different energies. In an octahedral complex, for example, the *d* orbitals divide into two groups: a higher-energy group ($d_{x^2-y^2}$ and d_{z^2}) and a lower-energy group (d_{xy}, d_{xz}, and d_{yz}).
- Electrons are assigned to metal *d* orbitals in a manner that leads to the lowest total energy. Two competing features determine the placement: the relative energy of the sets of orbitals and the electron pairing energy.
- For the electron configurations of d^4, d^5, d^6, and d^7 in octahedral complexes, two electron configurations are possible: high spin, which occurs when the orbital splitting is small, and low spin, which occurs with a large orbital splitting. To determine whether a complex is high spin or low spin, its magnetism can be measured to determine the number of unpaired electrons.
- The *d*-orbital splitting (the energy difference between the metal *d*-orbital energies) often corresponds to the energy associated with visible light. As a consequence, many metal complexes absorb visible light and thus are colored.

Most complexes of Pd^{2+} and Pt^{2+} ions are square-planar, the electron configuration of these metals being [noble gas]$(n-1)d^8$. In a square-planar complex, there are four sets of orbitals (see Figure 22.22). For square-planar d^8 complexes, all except the highest-energy orbital are filled, and all electrons are paired, resulting in diamagnetic (low-spin) complexes.

Nickel, which is found above palladium in the periodic table, forms both square-planar and tetrahedral complexes (as well as octahedral complexes). For example, the complex ion $[Ni(CN)_4]^{2-}$ is square-planar, whereas the $[NiCl_4]^{2-}$ ion is tetrahedral. Magnetism allows us to differentiate between these two geometries. Based on the ligand field splitting pattern, the cyanide complex is expected to be diamagnetic, whereas the chloride complex is paramagnetic with two unpaired electrons.



Nickel(II) complexes and magnetism. The anion $[NiCl_4]^{2-}$ is a paramagnetic tetrahedral complex. In contrast, $[Ni(CN)_4]^{2-}$ is a diamagnetic square-planar complex.

EXAMPLE 22.5

High- and Low-Spin Complexes and Magnetism

Problem Give the electron configuration for the metal ion in each of the following complexes. How many unpaired electrons are present in each? Are the complexes paramagnetic or diamagnetic?

(a) Low-spin $[Co(NH_3)_6]^{3+}$ (b) High-spin $[CoF_6]^{3-}$

What Do You Know? From their formulas, we know that these have six ligands and we can presume that they have octahedral geometry. Both are complexes of cobalt(III), a metal ion with a d^6 configuration. One complex is low spin, the other high spin.

Strategy Set up an energy-level diagram for an octahedral complex. In low-spin complexes, the electrons are added preferentially to the lower-energy set of orbitals. In high-spin complexes, the first five electrons are added singly to each of the five orbitals, then additional electrons are paired with electrons in orbitals in the lower-energy set.

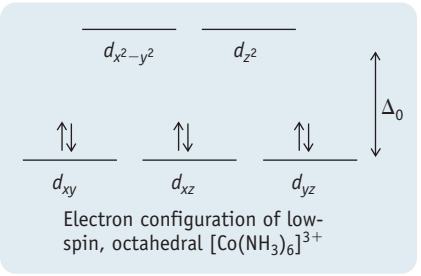
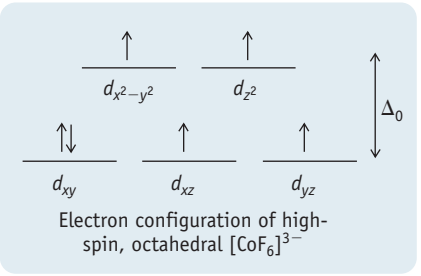
Solution



(a)



(b)

(a) The six electrons of the Co^{3+} ion fill the lower-energy set of orbitals entirely. This d^6 complex ion has no unpaired electrons and is diamagnetic.

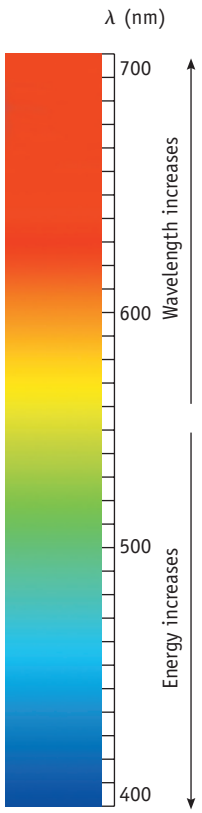
(b) To obtain the electron configuration in high-spin $[CoF_6]^{3-}$, place one electron in each of the five *d* orbitals, and then place the sixth electron in one of the lower-energy orbitals. The complex has four unpaired electrons and is paramagnetic.

Think about Your Answer The two complexes have different magnetic properties; low-spin $[Co(NH_3)_6]^{3+}$ is diamagnetic and high-spin $[CoF_6]^{3-}$ is paramagnetic.

Check Your Understanding

For each of the following complex ions, give the oxidation number of the metal, depict possible low- and high-spin configurations, give the number of unpaired electrons in each configuration, and tell whether each is paramagnetic or diamagnetic.

(a) $[Ru(H_2O)_6]^{2+}$ (b) $[Ni(NH_3)_6]^{2+}$



The ROY G BIV spectrum of colors of visible light. The colors used in printing this book are cyan, magenta, yellow, and black. The blue in ROY G BIV is actually cyan, according to color industry standards. Magenta doesn't have its own wavelength region. Rather, it is a mixture of blue and red.

REVIEW & CHECK FOR SECTION 22-5

1. Which of the following complexes has the greatest number of unpaired electrons?
   (a) Low-spin $[Fe(CN)_6]^{4-}$ (c) $[V(H_2O)_6]^{3+}$
   (b) High-spin $[Mn(NH_3)_6]^{2+}$ (d) $[Ni(en)_3]^{2+}$ (en = ethylenediamine)
2. Which of the following complexes is diamagnetic?
   (a) Square-planar $[PtCl_4]^{2-}$ (c) $[Fe(H_2O)_6]^{3+}$
   (b) Tetrahedral $[NiCl_4]^{2-}$ (d) High-spin $[CoF_6]^{3-}$

22-6 Colors of Coordination Compounds

The range of colors observed for compounds of the transition elements is one of their most interesting features (Figures 22.2 and 22.25), and the underlying reason for this is *d*-orbital splitting due to the ligands surrounding the metal atom or ion. Before discussing how *d*-orbital splitting is involved, however, let us look more closely at what we mean by color.

Color

Visible light, consists of radiation with wavelengths from 400 to 700 nm (◀ Section 6-1). Within this region are all the colors you see when white light passes through a prism: red, orange, yellow, green, blue, indigo, and violet (ROY G BIV). Each color is identified with a portion of the wavelength range.

Isaac Newton did experiments with light and established that the mind's perception of color requires only three colors! When we see white light, we are seeing a

FIGURE 22.25 Aqueous solutions of some transition metal ions. Compounds of transition metal elements are often colored, whereas those of main group metals are usually colorless. Pictured here, from *left* to *right,* are solutions of the nitrate salts of Fe^{3+}, Co^{2+}, Ni^{2+}, Cu^{2+}, and Zn^{2+}.

mixture of all of the colors—in other words, the superposition of red, green, and blue. If one or more of these colors is absent, the light of the other colors that reaches your eyes is interpreted by your mind as color.

Figure 22.26 will help you in analyzing perceived colors. The three primary colors—red, green, and blue—are shown as overlapping disks arranged in a triangle. The secondary colors—cyan, magenta, and yellow—appear where two disks overlap. The overlap of all three disks in the center produces white light.

The colors we perceive are determined as follows:

- Light of a single primary color is perceived as that color: Red light is perceived as red, green light as green, blue light as blue.
- Light made up of two primary colors is perceived as the color shown where the disks in Figure 22.26 overlap: Red and green light together appear yellow, green and blue light together are perceived as cyan; and red and blue light are perceived as magenta.
- Light made up of the three primary colors is white (colorless).

In discussing the color of a substance such as a coordination complex *in solution,* we are interested in the light that is absorbed.

- Red color is the result of the absorption of green and blue light by the solution.
- Green color results if red and blue light are absorbed.
- Blue color results if red and green light are absorbed.

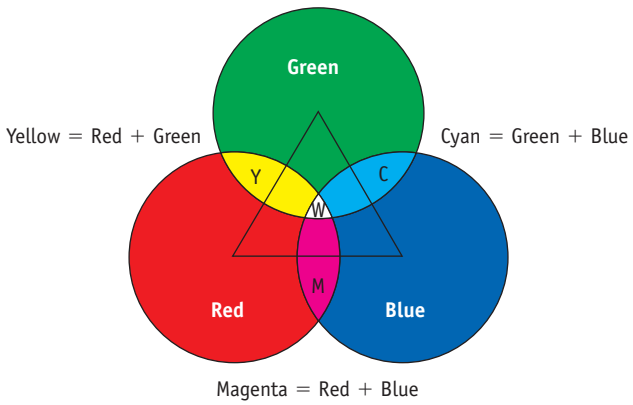

FIGURE 22.26 Using color disks to analyze colors. The three primary colors are red, green, and blue. Adding light of two primary colors gives the secondary colors yellow (= red + green), cyan (= green + blue), and magenta (= red + blue). Adding all three primary colors results in white light.

FIGURE 22.27 Light absorption and color. The color of a solution is due to the color of the light *not* absorbed by the solution. Here, a solution of Ni^{2+} ion in water absorbs red and blue light and so appears green (see also Figures 4.13–4.15).

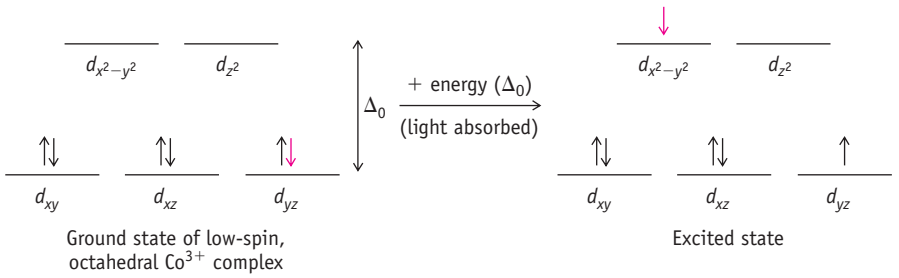
The secondary colors are rationalized similarly. Absorption of blue light gives yellow (the color across from it in Figure 22.26); absorption of red light results in cyan; and absorption of green light results in magenta.

Now we can apply these ideas to explain colors in transition metal complexes. Focus on what kind of light is *absorbed*. A solution of $[Ni(H_2O)_6]^{2+}$ is green. Green light is the result of removing red and blue light from white light. As white light passes through an aqueous solution of Ni^{2+}, red and blue light are absorbed, and green light is allowed to pass (Figure 22.27). Similarly, the $[Co(NH_3)_6]^{3+}$ ion is yellow because blue light has been absorbed and red and green light pass through.

The Spectrochemical Series

Recall that atomic spectra are obtained when electrons are excited from one energy level to another (◀ Section 6-3). The energy of the light absorbed or emitted is related to the energy levels of the atom or ion. The concept that light is absorbed when electrons are excited from lower to higher energy levels applies not just to atoms but also to ions and molecules of all types, including transition metal complexes.

In coordination complexes, the splitting between *d* orbitals often corresponds to the energy of visible light, so light in the visible region of the spectrum is absorbed when electrons move from a lower-energy *d* orbital to a higher-energy *d* orbital. This change, as an electron moves between two orbitals having different energies in a complex, is called a ***d*-to-*d* transition**. Qualitatively, such a transition for $[Co(NH_3)_6]^{3+}$ might be represented using an energy-level diagram such as that shown here.



Experiments with coordination complexes reveal that, for a given metal ion, some ligands cause a small energy separation of the *d* orbitals, whereas others cause a large separation. In other words, some ligands create a small ligand field, and others create a large one. An example is seen in the spectroscopic data for several cobalt(III) complexes presented in Table 22.3.

- Both $[Co(NH_3)_6]^{3+}$ and $[Co(en)_3]^{3+}$ are yellow-orange, because they absorb light in the blue portion of the visible spectrum. These compounds have very similar spectra, to be expected because in both the metal is coordinated to six N donor atoms.
- Although $[Co(CN)_6]^{3-}$ does not have an absorption band whose maximum falls in the visible region, it is pale yellow. The peak of the absorption band occurs in the ultraviolet region, but the absorption band is broad and extends minimally into the visible (blue) region.
- $[Co(C_2O_4)_3]^{3-}$ and $[Co(H_2O)_6]^{3+}$ have similar absorptions, in the yellow and violet regions. Their colors are shades of green with a small difference due to the relative amount of light of each color being absorbed.
- Of the complex ions in Table 22.3, $[CoF_6]^{3-}$ absorbs the lowest energy light (red) and so transmits the highest energy light (blue).

The wavelength of maximum absorption among the listed complexes ranges from 700 nm for $[CoF_6]^{3-}$ to 310 nm for $[Co(CN)_6]^{3-}$. The ligands change from member to member of this series, and we can conclude that the energy of the light absorbed by the complex is related to the different ligand field splittings, Δ_0, caused by the

Steven Hyatt

Green jade. This photo shows the entire piece of jade that is featured on the cover of this book. The rich green color comes from iron(II) and iron(III) ions in the mineral. It is likely that the iron ions within the mineral are surrounded by oxide ions at the corners of an octahedron.

Table 22.3 The Colors of Some Co^{3+} Complexes*

Complex Ion	Wavelength of Light Absorbed (nm)	Color of Light Absorbed	Color of Complex
$[CoF_6]^{3-}$	700	Red	Blue
$[Co(C_2O_4)_3]^{3-}$	600, 420	Yellow, violet	Dark green
$[Co(H_2O)_6]^{3+}$	600, 400	Yellow, violet	Blue-green
$[Co(NH_3)_6]^{3+}$	475, 340	Blue, ultraviolet	Yellow-orange
$[Co(en)_3]^{3+}$	470, 340	Blue, ultraviolet	Yellow-orange
$[Co(CN)_6]^{3-}$	310	Ultraviolet	Pale yellow

*The complex with fluoride ion, $[CoF_6]^{3-}$, is high spin and has one absorption band. The other complexes are low spin and have two absorption bands. In all but one case, one of these absorptions occurs in the visible region of the spectrum. The wavelengths are measured at the top of that absorption band.

CASE STUDY The Rare Earths

The lanthanide elements are often referred to as "rare earth elements." But what elements are really included in the list and why are they called "rare"? And what are they used for?

In this book we include the 14 elements from Ce (cerium) through Lu (lutetium) in the list of rare earths, but it is common to also include La, lanthanum. In addition, if you read about rare earth chemistry, the Group 3B elements Sc (scandium) and Y (yttrium) are often added to the list.

Why are they called "rare earth elements" and are they in fact "rare"? In 1803 German and Swedish chemists isolated a new oxide (an "earth") from a mineral found in Sweden. At first this was thought to be an oxide of a new element, cerium, but several decades later it was discovered that the "earth" was a mixture of cerium oxide and oxides of other lanthanides. The term "rare" has been attached to the elements because it is difficult to find them in concentrations great enough for commercial purposes and because they are difficult to separate one from another. But they are in fact rather abundant. Cerium, for example, is 26th most abundant in Earth's crust, about half as abundant as chlorine and 5 times as abundant as lead.

© Cengage Learning/Charles D. Winters

Compact fluorescent bulbs. They have an inside coating of a phosphorescent europium compound.

The elements were slow to find commercial uses, but some are now crucially important in our modern economy. Cerium(IV) oxide is used in catalysts and in the coatings of self-cleaning ovens. Neodymium (Nd) and samarium (Sm) are both used to make powerful magnets. Europium (Eu) is used in the phosphors inside compact fluorescent lightbulbs. (This coating is what allows the bulb to emit a very bright light.) Other uses are in batteries and wind turbines.

One consequence of the growing importance of the rare earths is that they are becoming scarce. China presently produces about 97% of the metals and oxides, and companies in the United States and elsewhere are opening old mines or seeking new sources.

Argonne National Laboratory

Cerium-based catalyst. A chemist at Argonne National Laboratory holds a beaker of Cu-ZSM-5 catalyst used to remove harmful nitrogen oxides from diesel exhaust. The catalyst is a zeolite that contains copper ions in the lattice and is coated with cerium(IV) oxide.

Questions:

1. What are the electron configurations for Nd and Eu?
2. The lanthanide elements form ionic compounds, with the 3+ oxidation state dominating. What are the electron configurations for Ce^{3+} and Nd^{3+}?
3. The compound $(NH_4)_2Ce(NO_3)_6$ is a widely used oxidizing agent in redox titrations. A 0.181 g sample of pure iron is dissolved in acid, reduced to Fe^{2+}, and then titrated with 31.33 mL of $(NH_4)_2Ce(NO_3)_6$ (to give Ce^{3+} and Fe^{3+}). Calculate the concentration of the cerium salt.
4. Cerium(IV) oxide is used in catalytic converters in the oxidation of CO (to give cerium(III) oxide and CO_2). The cerium(III) oxide is converted back to cerium(IV) oxide by atmospheric oxygen. Balance equations for these reactions.

The answers to these questions are found in Appendix N.

different ligands. Fluoride ion causes the smallest splitting of the *d* orbitals among the complexes listed in Table 22.3, whereas cyanide causes the largest splitting.

Spectra of complexes of other metals provide similar results. Based on this information, ligands can be listed in order of their ability to split the *d* orbitals. This list is called the **spectrochemical series** because it was determined by spectroscopy. A short list, with some of the more common ligands, follows:

$$\underset{\substack{\text{small } d \text{ orbital splitting}\\ \text{small } \Delta_0}}{F^-,\ Cl^-,\ Br^-,\ I^-} < \underset{}{C_2O_4^{2-}} < \underset{}{H_2O} < \underset{}{NH_3} = \underset{}{en} < \underset{}{phen} < \underset{\substack{\text{large } d \text{ orbital splitting}\\ \text{large } \Delta_0}}{CN^-}$$

The spectrochemical series is applicable to a wide range of metal complexes. Indeed, the ability of ligand field theory to explain the differences in the colors of the transition metal complexes is one of the strengths of this theory.

Based on the relative position of a ligand in the series, predictions can be made about a compound's magnetic behavior. Recall that d^4, d^5, d^6, and d^7 complexes can be high or low spin, depending on the ligand field splitting, Δ_0. Complexes formed with ligands near the left end of the spectrochemical series are expected to have small Δ_0 values and, therefore, are likely to be high spin. In contrast, complexes with ligands near the right end are expected to have large Δ_0 values and low-spin configurations. The complex $[CoF_6]^{3-}$ is high spin, whereas $[Co(NH_3)_6]^{3+}$ and the other complexes in Table 22.3 are low spin.

EXAMPLE 22.6

Spectrochemical Series

Problem An aqueous solution of $[Fe(H_2O)_6]^{2+}$ is light blue-green. Do you expect the d^6 Fe^{2+} ion in this complex to have a high- or low-spin configuration? How could you test your prediction experimentally?

What Do You Know? This is an octahedral complex of Fe^{2+}, an ion with a d^6 configuration. The blue-green color is the result of the absorption of visible light due to a *d*-to-*d* transition. The complex could be either low spin (no unpaired electrons) or high spin (four unpaired electrons).

Strategy Use the color wheel in Figure 22.26 to determine what color light is transmitted and therefore what color of light has been absorbed. Based on the energy of the light absorbed, determine if Δ_0 is high or low. If it is low, then the complex is high spin. If it is high, then the complex is low spin.

Solution In this case, the blue-green color of the solution indicates that blue and green light is transmitted. This implies that red light was absorbed. The low energy of the light absorbed suggests that Δ_0 is small and so $[Fe(H_2O)_6]^{2+}$ is likely to be a high-spin complex. If the complex is high spin, it will have four unpaired electrons and be paramagnetic; if, contrary to our prediction, it is low spin, it will have no unpaired electrons and be diamagnetic. Thus, identifying the presence of four unpaired electrons by measuring the compound's magnetism can be used to verify the high-spin configuration experimentally.

Think about Your Answer The spectrochemical series was generated by measuring the absorptions for a series of complexes of a given metal, varying the ligands. As in the example here, the spectrochemical series is useful because it allows you to predict whether a complex is likely to be high or low spin. The more definitive evidence for high or low spin comes from information on the magnetism of the complex.

Check Your Understanding

1. The complex $[Co(NH_3)_5OH]^{2+}$ has an absorption maximum at 500 nm. What color of light is absorbed and what color is the complex?
2. Figure 22.15 shows a sample of yellow $[Co(NH_3)_5NO_2]^{2+}$. What color of light is absorbed by this complex? Predict whether this is a high-spin or low-spin complex.

REVIEW & CHECK FOR SECTION 22-6

1. Solutions of each of the following complexes absorb light in the visible region of the spectrum. Predict which complex will absorb light of the longest wavelength.

   (a) $[Cr(H_2O)_6]^{3+}$ (b) $[Cr(NH_3)_6]^{3+}$ (c) $[CrF_6]^{3-}$ (d) $[Cr(CN)_6]^{3-}$

APPLYING CHEMICAL PRINCIPLES

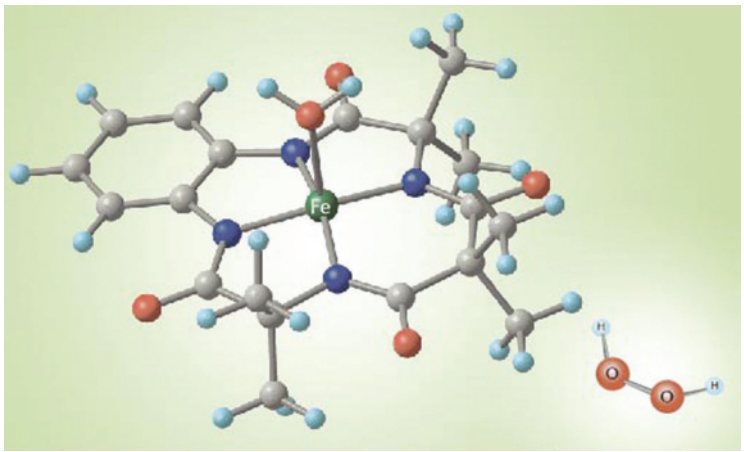
Green Catalysts

You were introduced to "green chemistry" in Chapter 1 and have seen several instances of it throughout the book. The important objective of this field is that a process that creates a useful product must have a negligible impact on the environment. Thus, important goals of green chemistry include eliminating the use of toxic substances as reactants and reducing the quantity of unwanted reaction by-products.

Catalysts can play an important role in green chemistry processes. Catalysts increase reaction rates sufficiently so that reactions can often be run at lower temperatures, thereby reducing energy usage. Catalysts may also improve the reaction specificity, yielding higher percentages of products, often in fewer synthetic steps. A specific area where green catalytic alternatives are needed is in oxidation reactions. At present these are often carried out by environmentally unfriendly compounds such as chlorine or chlorine dioxide.

Terry Collins, Professor of Chemistry at the Carnegie Mellon Institute for Green Chemistry, has designed a family of iron-based coordination complexes that are promising oxidation catalysts. Named Fe-TAML® (where TAML stands for tetraamido-macrocyclic ligand), these complexes catalyze reactions using hydrogen peroxide as an oxidizing agent. Hydrogen peroxide is an environmentally friendly oxidizing agent. However, when used without a suitable catalyst, H_2O_2 decomposes it tends to produce hydroxyl radicals that indiscriminately attack organic molecules.

Recently, this catalyst has shown positive results in the treatment of waste water from wood pulp treatment plants. Wood pulp consists of two naturally occurring polymers, cellulose and lignin. Cellulose is used for making white paper, whereas lignin is a dark colored polymer that must be removed. Current practice is to oxidize the lignin with chlorine dioxide before releasing it into waste water. However, all the lignin is destroyed in this process, and the remaining lignin darkens the water and affects the quantity of light absorbed by aquatic life. Low concentrations of Fe-TAML (500 nanomolar) combined with small amounts of hydrogen peroxide have been shown to destroy the majority of lignin quickly at room temperature.



Courtesy of Professor Terry Collins, The Institute for Green Science, Carnegie Mellon University

The prototype TAML activator. A model of hydrogen peroxide is also shown. The central iron cation is coordinated to four nitrogen atoms and a water molecule. The geometry around the central iron atom is square pyramidal. (Model from the Institute for Green Science: www.chem.cmu.edu/groups/collins.)

QUESTIONS:

Answer the following questions concerning the Fe-TAML catalyst in the Figure.

1. What is the coordination number of the metal in the Fe-TAML catalyst?
2. Fe-TAML, as pictured here, is a complex ion of a macrocyclic ligand (with a charge of 4−), a water molecule, and an iron(III) ion. What is the overall charge on the Fe-TAML complex ion?
3. TAML is a tetra_____ macrocyclic ligand, meaning it has four "teeth" that can bond to the metal.
4. Can this metal–ligand complex have any isomers?
5. What is the geometry of the coordinating atoms around the Fe^{3+} ion in the Fe-TAML complex ion if the water is removed: tetrahedral, square-planar, square-pyramidal, or octahedral?

REFERENCES AND NOTES:

1. Professor Terry Collins, whose research group developed the Fe-TAML catalyst, received the 1999 Presidential Green Chemistry Challenge Award.

CHAPTER GOALS REVISITED

Now that you have studied this chapter, you should ask whether you have met the chapter goals. In particular, you should be able to:

UNDERSTAND

- Ligand field theory description of metal-ligand bonding in coordination compounds (Section 22-5).
- Isomerism and its occurrence in coordination chemistry (Sections 22-3 and 22-4).
- How color and magnetism are related to the electronic structure of a complex (Section 22-6). Study Questions: 23–30, 34, 35, 42, 43, 50, 53, 54, 58, 61.
- How spectroscopy and magnetism can be used to identify high- and low-spin complexes (Section 22-5). Study Questions: 29, 30, 54.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

DO

- Given the formula for a coordination complex, identify the metal and its oxidation state, the ligands, the coordination number and coordination geometry, and the overall charge on the complex (Section 22-3 and 22-4). Study Questions: 9–12, 46, 47.
- Given the molecular formula of a complex, determine whether isomers are possible, and draw their structures (Section 22-4). Study Questions: 39, 42, 43, 45, 46.
- Given a formula, name a complex; given a name of a complex, write its formula (Section 22-4). Study Questions: 13–18.
- Draw an energy level diagram representing splitting of the metal *d* orbitals by the ligand field (Section 22-5). Study Question: 40.
- Apply the principles of stoichiometry, thermodynamics, and equilibrium to transition metal compounds. Study Questions: 62, 70.

REMEMBER

- General chemical and physical properties of common transition metal elements.
  - **a.** Identify the general classes of transition elements (Section 22-1).
  - **b.** Identify the transition metals from their symbols and positions in the periodic table, and recall some physical and chemical properties (Section 22-1).
  - **c.** Understand the electrochemical nature of corrosion (Section 22-1).
  - **d.** Describe the metallurgy of iron and copper (Section 22-2).
- The terminology of coordination chemistry: coordination number and coordination geometry, ligand, chelate, bidentate (Sections 22-3 and 22-4).
- The terminology of ligand field theory: low spin and high spin, ligand field splitting (Section 22-5).
- The names and formulas for common ligands (Sections 22-3 and 22-4).

Steven Hyatt

STUDY QUESTIONS

▲ denotes challenging questions.

Blue-numbered questions have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Properties of Transition Elements

(See Section 22-1 and Examples 7.3 and 7.4.)

1. Give the electron configuration for each of the following ions, and tell whether each is paramagnetic or diamagnetic.

(a) Cr^{3+} (c) Ni^{2+}
(b) V^{2+} (d) Cu^{+}

2. Identify two transition metal cations with each of the following electron configurations.

(a) $[Ar]3d^6$ (c) $[Ar]3d^5$
(b) $[Ar]3d^{10}$ (d) $[Ar]3d^8$

3. Identify a cation of a first series transition metal that is isoelectronic with each of the following.

(a) Fe^{3+} (c) Fe^{2+}
(b) Zn^{2+} (d) Cr^{3+}

4. Match up the isoelectronic ions on the following list.

$$Cu^{+}\ Mn^{2+}\ Fe^{2+}\ Co^{3+}\ Fe^{3+}\ Zn^{2+}\ Ti^{2+}\ V^{3+}$$

5. The following equations represent various ways of obtaining transition metals from their compounds. Balance each equation.

(a) $Cr_2O_3(s) + Al(s) \longrightarrow Al_2O_3(s) + Cr(s)$
(b) $TiCl_4(\ell) + Mg(s) \longrightarrow Ti(s) + MgCl_2(s)$
(c) $[Ag(CN)_2]^-(aq) + Zn(s) \longrightarrow Ag(s) + [Zn(CN)_4]^{2-}(aq)$
(d) $Mn_3O_4(s) + Al(s) \longrightarrow Mn(s) + Al_2O_3(s)$

6. Identify the products of each reaction, and balance the equation.

(a) $CuSO_4(aq) + Zn(s) \longrightarrow$
(b) $Zn(s) + HCl(aq) \longrightarrow$
(c) $Fe(s) + Cl_2(g) \longrightarrow$
(d) $V(s) + O_2(g) \longrightarrow$

Formulas of Coordination Compounds

(See Examples 22.1 and 22.2.)

7. Which of the following ligands is expected to be monodentate, and which might be polydentate?

(a) CH_3NH_2 (d) en
(b) CH_3CN (e) Br^-
(c) N_3^- (f) phen

8. One of the following nitrogen compounds or ions is not capable of serving as a ligand: NH_4^+, NH_3, NH_2^-. Identify this species, and explain your answer.

9. Give the oxidation number of the metal ion in each of the following compounds.

(a) $[Mn(NH_3)_6]SO_4$ (c) $[Co(NH_3)_4Cl_2]Cl$
(b) $K_3[Co(CN)_6]$ (d) $Cr(en)_2Cl_2$

10. Give the oxidation number of the metal ion in each of the following complexes.

(a) $[Fe(NH_3)_6]^{2+}$ (c) $[Co(NH_3)_5(NO_2)]^+$
(b) $[Zn(CN)_4]^{2-}$ (d) $[Cu(en)_2]^{2+}$

11. Give the formula of a complex constructed from one Ni^{2+} ion, one ethylenediamine ligand, three ammonia molecules, and one water molecule. Is the complex neutral or is it charged? If charged, give the charge.

12. Give the formula of a complex constructed from one Cr^{3+} ion, two ethylenediamine ligands, and two ammonia molecules. Is the complex neutral or is it charged? If charged, give the charge.

Naming Coordination Compounds

(See Example 22.3.)

13. Write formulas for the following ions or compounds.

(a) dichlorobis(ethylenediamine)nickel(II)
(b) potassium tetrachloroplatinate(II)
(c) potassium dicyanocuprate(I)
(d) tetraamminediaquairon(II)

14. Write formulas for the following ions or compounds.

(a) diamminetriaquahydroxochromium(II) nitrate
(b) hexaammineiron(III) nitrate
(c) pentacarbonyliron(0) (where the ligand is CO)
(d) ammonium tetrachlorocuprate(II)

15. Name the following ions or compounds.

(a) $[Ni(C_2O_4)_2(H_2O)_2]^{2-}$ (c) $[Co(en)_2(NH_3)Cl]^{2+}$
(b) $[Co(en)_2Br_2]^+$ (d) $Pt(NH_3)_2(C_2O_4)$

16. Name the following ions or compounds.

(a) $[Co(H_2O)_4Cl_2]^+$ (c) $[Pt(NH_3)Br_3]^-$
(b) $Co(H_2O)_3F_3$ (d) $[Co(en)(NH_3)_3Cl]^{2+}$

17. Give the name or formula for each ion or compound, as appropriate.

(a) pentaaquahydroxoiron(III) ion
(b) $K_2[Ni(CN)_4]$
(c) $K[Cr(C_2O_4)_2(H_2O)_2]$
(d) ammonium tetrachloroplatinate(II)

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

18. Give the name or formula for each ion or compound, as appropriate.

(a) tetraaquadichlorochromium(III) chloride
(b) $[Cr(NH_3)_5SO_4]Cl$
(c) sodium tetrachlorocobaltate(II)
(d) $[Fe(C_2O_4)_3]^{3-}$

Isomerism

(See Example 22.4.)

19. Draw all possible geometric isomers for each of the following ions or molecules.

(a) $Fe(NH_3)_4Cl_2$
(b) $Pt(NH_3)_2(SCN)(Br)$ (SCN^- is bonded to Pt^{2+} through S)
(c) $Co(NH_3)_3(NO_2)_3$ (NO_2^- is bonded to Co^{3+} through N)
(d) $[Co(en)Cl_4]^-$

20. In which of the following complexes are geometric isomers possible? If isomers are possible, draw their structures and label them as *cis* or *trans*, or as *fac* or *mer*.

(a) $[Co(H_2O)_4Cl_2]^+$
(b) $Co(NH_3)_3F_3$
(c) $[Pt(NH_3)Br_3]^-$
(d) $[Co(en)_2(NH_3)Cl]^{2+}$

21. Determine whether the following complexes have a chiral metal center.

(a) $[Fe(en)_3]^{2+}$
(b) *trans*-$[Co(en)_2Br_2]^+$
(c) *fac*-$[Co(en)(H_2O)Cl_3]$
(d) square-planar $Pt(NH_3)(H_2O)(Cl)(NO_2)$

22. Four geometric isomers are possible for $[Co(en)(NH_3)_2(H_2O)Cl]^+$. Draw the structures of all four. (Two of the isomers are chiral, meaning that each has a non-superimposable mirror image.)

Magnetic Properties of Complexes

(See Example 22.5.)

23. The following are low-spin complexes. Use the ligand field model to find the electron configuration of the central metal ion in each ion. Determine which are diamagnetic. Give the number of unpaired electrons for the paramagnetic complexes.

(a) $[Mn(CN)_6]^{4-}$
(b) $[Co(NH_3)_6]Cl_3$
(c) $[Fe(H_2O)_6]^{3+}$
(d) $[Cr(en)_3]SO_4$

24. The following are high-spin complexes. Use the ligand field model to find the electron configuration of the central metal ion in each ion. Determine the number of unpaired electrons, if any, in each.

(a) $K_4[FeF_6]$
(b) $[MnF_6]^{4-}$
(c) $[Cr(H_2O)_6]^{2+}$
(d) $(NH_4)_3[FeF_6]$

25. Determine the number of unpaired electrons in the following tetrahedral complexes. All tetrahedral complexes are high spin.

(a) $[FeCl_4]^{2-}$
(b) $Na_2[CoCl_4]$
(c) $[MnCl_4]^{2-}$
(d) $(NH_4)_2[ZnCl_4]$

26. Determine the number of unpaired electrons in the following tetrahedral complexes. All tetrahedral complexes are high spin.

(a) $[Zn(H_2O)_4]^{2+}$
(b) $VOCl_3$
(c) $Mn(NH_3)_2Cl_2$
(d) $[Cu(en)_2]^{2+}$

27. For the high-spin complex $[Fe(H_2O)_6]SO_4$, identify the following:

(a) the coordination number of iron
(b) the coordination geometry for iron
(c) the oxidation number of iron
(d) the number of unpaired electrons
(e) whether the complex is diamagnetic or paramagnetic

28. For the low-spin complex $[Co(en)(NH_3)_2Cl_2]ClO_4$, identify the following:

(a) the coordination number of cobalt
(b) the coordination geometry for cobalt
(c) the oxidation number of cobalt
(d) the number of unpaired electrons
(e) whether the complex is diamagnetic or paramagnetic
(f) Draw any geometric isomers.

29. The anion $[NiCl_4]^{2-}$ is paramagnetic, but when CN^- ions are added, the product, $[Ni(CN)_4]^{2-}$, is diamagnetic. Explain this observation.

$$\underset{\text{paramagnetic}}{[NiCl_4]^{2-}(aq)} + 4\ CN^-(aq) \longrightarrow \underset{\text{diamagnetic}}{[Ni(CN)_4]^{2-}(aq)} + 4\ Cl^-(aq)$$

30. An aqueous solution of iron(II) sulfate is paramagnetic. If NH_3 is added, the solution becomes diamagnetic. Why does the magnetism change?

Spectroscopy of Complexes

(See Example 22.6.)

31. In water, the titanium(III) ion, $[Ti(H_2O)_6]^{3+}$, has a broad absorption band centered at about 500 nm. What color light is absorbed by the ion?

32. In water, the chromium(II) ion, $[Cr(H_2O)_6]^{2+}$, absorbs light with a wavelength of about 700 nm. What color is the solution?

General Questions

These questions are not designated as to type or location in the chapter. They may contain several concepts.

33. Describe an experiment that would determine whether nickel in $K_2[NiCl_4]$ is square-planar or tetrahedral.

34. Which of the following high-spin complexes has the greatest number of unpaired electrons?

(a) $[Cr(H_2O)_6]^{3+}$
(b) $[Mn(H_2O)_6]^{2+}$
(c) $[Fe(H_2O)_6]^{2+}$
(d) $[Ni(H_2O)_6]^{2+}$

35. How many unpaired electrons are expected for high-spin and low-spin complexes of Fe^{2+}?

36. Excess silver nitrate is added to a solution containing 1.0 mol of $[Co(NH_3)_4Cl_2]Cl$. What amount of AgCl (in moles) will precipitate?

37. Which of the following complex ions is (are) square-planar?

(a) $[Ti(CN)_4]^{2-}$ (c) $[Zn(CN)_4]^{2-}$
(b) $[Ni(CN)_4]^{2-}$ (d) $[Pt(CN)_4]^{2-}$

38. Which of the following complex ions containing the oxalate ion is (are) chiral?

(a) $[Fe(C_2O_4)Cl_4]^{2-}$
(b) *cis*-$[Fe(C_2O_4)_2Cl_2]^{2-}$
(c) *trans*-$[Fe(C_2O_4)_2Cl_2]^{2-}$

39. How many geometric isomers are possible for the square-planar complex ion $[Pt(NH_3)(CN)Cl_2]^-$?

40. For a tetrahedral complex of a metal in the first transition series, which of the following statements concerning energies of the 3*d* orbitals is correct?

(a) The five *d* orbitals have the same energy.
(b) The $d_{x^2-y^2}$ and d_{z^2} orbitals are higher in energy than the d_{xz}, d_{yz}, and d_{xy} orbitals.
(c) The d_{xz}, d_{yz}, and d_{xy} orbitals are higher in energy than the $d_{x^2-y^2}$ and d_{z^2} orbitals.

41. A transition metal coordination compound absorbs 425-nm light. What is its color?

(a) red (c) yellow
(b) green (d) blue

42. For the low-spin coordination compound $[Fe(en)_2Cl_2]Cl$, identify the following.

(a) the oxidation number of iron
(b) the coordination number for iron
(c) the coordination geometry for iron
(d) the number of unpaired electrons per metal atom
(e) whether the complex is diamagnetic or paramagnetic
(f) the number of geometric isomers

43. For the high-spin coordination compound $Mn(NH_3)_4Cl_2$, identify the following.

(a) the oxidation number of manganese
(b) the coordination number for manganese
(c) the coordination geometry for manganese
(d) the number of unpaired electrons per metal atom
(e) whether the complex is diamagnetic or paramagnetic
(f) the number of geometric isomers

44. A platinum-containing compound, known as Magnus's green salt, has the formula $[Pt(NH_3)_4][PtCl_4]$ (in which both platinum ions are Pt^{2+}). Name the cation and the anion.

45. Early in the 20th century, coordination compounds sometimes were given names based on their colors. Two compounds with the formula $CoCl_3 \cdot 4\ NH_3$ were named praseo-cobalt chloride (*praseo* = green) and violio-cobalt chloride (violet color). We now know that these compounds are octahedral cobalt complexes and that they are *cis* and *trans* isomers. Draw the structures of these two compounds, and name them using systematic nomenclature.

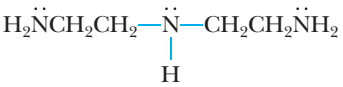
46. Give the formula and name of a square-planar complex of Pt^{2+} with one nitrite ion (NO_2^-, which binds to Pt^{2+} through N), one chloride ion, and two ammonia molecules as ligands. Are isomers possible? If so, draw the structure of each isomer, and tell what type of isomerism is observed.

47. Give the formula of the coordination complex formed from one Co^{3+} ion, two ethylenediamine molecules, one water molecule, and one chloride ion. Is the complex neutral or charged? If charged, give the net charge on the ion.

48. ▲ How many geometric isomers of the complex ion $[Cr(dmen)_3]^{3+}$ can exist? (dmen is the bidentate ligand 1,1-dimethylethylenediamine.)

1,1-Dimethylethylenediamine, dmen

49. ▲ Diethylenetriamine (dien) is capable of serving as a tridentate ligand.



Diethylenetriamine, dien

(a) Draw the structures of *fac*-$Cr(dien)Cl_3$ and *mer*-$Cr(dien)Cl_3$.
(b) Two different geometric isomers of *mer*-$Cr(dien)Cl_2Br$ are possible. Draw the structure for each.
(c) Three different geometric isomers are possible for $[Cr(dien)_2]^{3+}$. Two have the dien ligand in a *fac* configuration, and one has the ligand in a *mer* orientation. Draw the structure of each isomer.

50. From experiment, we know that $[CoF_6]^{3-}$ is paramagnetic and $[Co(NH_3)_6]^{3+}$ is diamagnetic. Using the ligand field model, depict the electron configuration for each ion, and use this model to explain the magnetic property. What can you conclude about the effect of these ligands on the magnitude of Δ_0?

51. Three geometric isomers are possible for $[Co(en)(NH_3)_2(H_2O)_2]^{3+}$. One of the three is chiral; that is, it has a nonsuperimposable mirror image. Draw the structures of the three isomers. Which one is chiral?

52. The square-planar complex $Pt(en)Cl_2$ has chloride ligands in a *cis* configuration. No *trans* isomer is known. Based on the bond lengths and bond angles of carbon and nitrogen in the ethylenediamine ligand, explain why the *trans* compound is not possible.

53. The complex $[Mn(H_2O)_6]^{2+}$ has five unpaired electrons, whereas $[Mn(CN)_6]^{4-}$ has only one. Using the ligand field model, depict the electron configuration for each ion. What can you conclude about the effects of the different ligands on the magnitude of Δ_0?

54. Experiments show that $K_4[Cr(CN)_6]$ is paramagnetic and has two unpaired electrons. The related complex $K_4[Cr(SCN)_6]$ is paramagnetic and has four unpaired electrons. Account for the magnetism of each compound using the ligand field model. Predict where the SCN^- ion occurs in the spectrochemical series relative to CN^-.

55. Give a systematic name or the formula for the following:

(a) $(NH_4)_2[CuCl_4]$
(b) tetraaquadichlorochromium(III) chloride
(c) aquabis(ethylenediamine)thiocyanatocobalt(III) nitrate

56. When $CrCl_3$ dissolves in water, three different species can be obtained.

(a) $[Cr(H_2O)_6]Cl_3$, violet
(b) $[Cr(H_2O)_5Cl]Cl_2$, pale green
(c) $[Cr(H_2O)_4Cl_2]Cl$, dark green

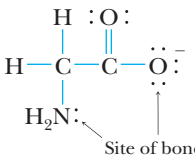
If diethyl ether is added, a fourth complex can be obtained: $Cr(H_2O)_3Cl_3$ (brown). Describe an experiment that will allow you to differentiate these complexes.

57. ▲ The complex ion $[Co(CO_3)_3]^{3-}$, an octahedral complex with bidentate carbonate ions as ligands, has one absorption in the visible region of the spectrum at 640 nm. From this information,

(a) Predict the color of this complex and explain your reasoning.
(b) Is the carbonate ion a weak- or strong-field ligand?
(c) Predict whether $[Co(CO_3)_3]^{3-}$ will be paramagnetic or diamagnetic.

58. The glycinate ion, $H_2NCH_2CO_2^-$, formed by deprotonation of the amino acid glycine, can function as a bidentate ligand, coordinating to a metal through the nitrogen of the amino group and one of the oxygen atoms.

Glycinate ion, a bidentate ligand



A copper complex of this ligand has the formula $Cu(H_2NCH_2CO_2)_2(H_2O)_2$. For this complex, determine the following:

(a) the oxidation state of copper
(b) the coordination number of copper
(c) the number of unpaired electrons
(d) whether the complex is diamagnetic or paramagnetic

59. ▲ Draw structures for the five possible geometric isomers of $Cu(H_2NCH_2CO_2)_2(H_2O)_2$. Are any of these species chiral? (See the structure of the ligand in Study Question 58.)

60. A manganese compound has the formula $Mn(CO)_x(CH_3)_y$. To find the empirical formula of the compound, you burn 0.225 g of the solid in oxygen and isolate 0.283 g of CO_2 and 0.0290 g of H_2O. What is the empirical formula for the compound? That is, what are the values of x and y?

61. Nickel and palladium both form complexes of the general formula $M(PR_3)_2Cl_2$. (The ligand PR_3 is a phosphine such as $P(C_6H_5)_3$, triphenylphosphine. It is Lewis base.) The nickel(II) compound is paramagnetic whereas the palladium(II) compound is diamagnetic.

(a) Explain the magnetic properties of these compounds.
(b) How many isomers of each compound are expected?

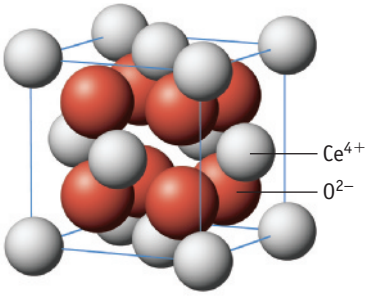
62. ▲ The transition metals form a class of compounds called metal carbonyls, an example of which is the tetrahedral complex $Ni(CO)_4$. Given the following thermodynamic data (at 298 K):

	$\Delta_f H°$ (kJ/mol)	$S°$ (J/K · mol)
Ni(s)	0	29.87
CO(g)	−110.525	+197.674
$Ni(CO)_4$(g)	−602.9	+410.6

(a) Calculate the equilibrium constant for the formation of $Ni(CO)_4$(g) from nickel metal and CO gas.
(b) Is the reaction of Ni(s) and CO(g) product- or reactant-favored at equilibrium?
(c) Is the reaction more or less product-favored at higher temperatures? How could this reaction be used in the purification of nickel metal?

63. Cerium, as noted in *Case Study: The Rare Earths* (page 891), is a relatively abundant lanthanide element that has some important uses. Cerium(IV) oxide, CeO_2, is widely used as a polishing agent for glass. Cerium(III) sulfide, Ce_2S_3, is becoming more widely used as a red pigment to replace cadmium pigments, which are environmentally less desirable.

(a) Give the electron configurations (using the noble gas notation) for Ce, Ce^{3+}, and Ce^{4+}.
(b) Is either Ce^{3+} or Ce^{4+} paramagnetic? If so, how many unpaired electrons does each have?
(c) The solid state structure for CeO_2 is shown below. Describe the unit cell of the compound. How is this structure related to the formula?



CeO_2

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

64. Neodymium is a component of powerful magnets.

(a) Neodymium is different than most lanthanides in that it has three common oxidation states: +2, +3, and +4. Give the electron configurations for Nd and its three positive oxidation states.

(b) Are any of the common Nd ions paramagnetic?

(c) Neodymium magnets, which are composed of Nd, Fe, and B, were developed because samarium-based magnets (SmCo) were very costly. What is the empirical formula for the neodymium-based magnet material if it is 26.68% Nd, 72.32% Fe, and the remainder B?

© Cengage Learning/Charles D. Winters

Neodymium magnets

In the Laboratory

65. Two different coordination compounds containing one cobalt(III) ion, five ammonia molecules, one bromide ion, and one sulfate ion exist. The dark violet form (A) gives a precipitate upon addition of aqueous $BaCl_2$. No reaction is seen upon addition of aqueous $BaCl_2$ to the violet-red form (B). Suggest structures for these two compounds, and write a chemical equation for the reaction of (A) with aqueous $BaCl_2$.

66. Three different compounds of chromium(III) with water and chloride ion have the same composition: 19.51% Cr, 39.92% Cl, and 40.57% H_2O. One of the compounds is violet and dissolves in water to give a complex ion with a 3+ charge and three chloride ions. All three chloride ions precipitate immediately as AgCl on adding $AgNO_3$. Draw the structure of the complex ion, and name the compound. Write a net ionic equation for the reaction of this compound with silver nitrate.

67. ▲ A 0.213-g sample of uranyl(VI) nitrate, $UO_2(NO_3)_2$, is dissolved in 20.0 mL of 1.0 M H_2SO_4 and shaken with Zn. The zinc reduces the uranyl ion, UO_2^{2+}, to a uranium ion, U^{n+}. To determine the value of n, this solution is titrated with $KMnO_4$. Permanganate is reduced to Mn^{2+} and U^{n+} is oxidized back to UO_2^{2+}.

(a) In the titration, 12.47 mL of 0.0173 M $KMnO_4$ was required to reach the equivalence point. Use this information to determine the charge on the ion U^{n+}.

(b) With the identity of U^{n+} now established, write a balanced net ionic equation for the reduction of UO_2^{2+} by zinc (assume acidic conditions).

(c) Write a balanced net ionic equation for the oxidation of U^{n+} to UO_2^{2+} by MnO_4^- in acid.

68. Fireworks contain $KClO_3$. To analyze a sample for the amount of $KClO_3$ a chemist first reacts the sample with excess iron(II),

$$ClO_3^-(aq) + 6\ Fe^{2+}(aq) + 6\ H_3O^+(aq) \longrightarrow Cl^-(aq) + 9\ H_2O(\ell) + 6\ Fe^{3+}(aq)$$

and then titrates the resulting solution with Ce^{4+} [in the form of $(NH_4)_2Ce(NO_3)_6$]

$$Fe^{2+}(aq) + Ce^{4+}(aq) \longrightarrow Fe^{3+}(aq) + Ce^{3+}(aq)$$

to determine the quantity of iron(II) that did not react with ClO_3^-. (This is referred to as a "back titration.") Suppose a 0.1342-g sample of a firework was treated with 50.00 mL of 0.0960 M Fe^{2+}. The unreacted Fe^{2+} ions then required 12.99 mL of 0.08362 M Ce^{4+}. What is the weight percent of $KClO_3$ in the original sample?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

69. The stability of analogous complexes $[ML_6]^{n+}$ (relative to ligand dissociation) is in the general order $Mn^{2+} < Fe^{2+} < Co^{2+} < Ni^{2+} < Cu^{2+} > Zn^{2+}$. This order of ions is called the Irving–Williams series. Look up the values of the formation constants for the ammonia complexes of Co^{2+}, Ni^{2+}, Cu^{2+}, and Zn^{2+} in Appendix K, and verify this statement.

70. ▲ In this question, we explore the differences between metal coordination by monodentate and bidentate ligands. Formation constants, K_f, for $[Ni(NH_3)_6]^{2+}(aq)$ and $[Ni(en)_3]^{2+}(aq)$ are as follows:

$$Ni^{2+}(aq) + 6\ NH_3(aq) \longrightarrow [Ni(NH_3)_6]^{2+}(aq) \qquad K_f = 10^8$$

$$Ni^{2+}(aq) + 3\ en(aq) \longrightarrow [Ni(en)_3]^{2+}(aq) \qquad K_f = 10^{18}$$

The difference in K_f between these complexes indicates a higher thermodynamic stability for the chelated complex, caused by the *chelate effect*. Recall that K is related to the standard free energy of the reaction by $\Delta_r G° = -RT \ln K$ and $\Delta_r G° = \Delta_r H° - T\Delta_r S°$. We know from experiment that $\Delta_r H°$ for the NH_3 reaction is −109 kJ/mol-rxn, and $\Delta_r H°$ for the ethylenediamine reaction is −117 kJ/mol-rxn. Is the difference in $\Delta_r H°$ sufficient to account for the 10^{10} difference in K_f? Comment on the role of entropy in the second reaction.

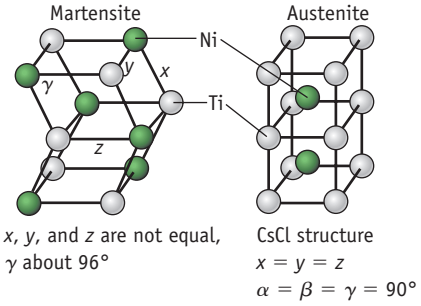
71. Nitinol, a nickel-titanium alloy, is used in eyeglass frames or orthodontics. If you bend a pair of eyeglass frames out of shape, they snap back to the proper fit. That is the reason nitinol is often called "memory metal."

NASA/Science Source

Memory metal is an alloy with roughly the same number of Ni and Ti atoms. When the atoms are arranged in the highly symmetrical austenite phase, the alloy is relatively rigid. In this phase a specific shape is established that will be "remembered." If the alloy is cooled below its "phase transition temperature," it enters a less symmetrical but flexible phase (martensite). Below this transition temperature, the metal is fairly soft and may be bent and twisted out of shape. When warmed above the phase transition temperature, nitinol returns to its original shape. The temperature at which the change in shape occurs varies with small differences in the nickel-to-titanium ratio.



Two phases of nitinol. The austenite form has a structure like CsCl.

(a) What are the dimensions of the austenite unit cell? Assume the Ti and Ni atoms are just touching along the unit cell diagonal. (Atom radii: Ti = 145 pm; Ni = 125 pm.)

(b) Calculate the density of nitinol based on the austenite unit cell parameters. Does the calculated density of the austenite unit cell agree with the reported density of 6.5 g/cm^3?

(c) Are Ti and Ni atoms paramagnetic or diamagnetic?

Cacao pods on a tree in an island in the Caribbean and the ultimate product.

Carbon: Not Just Another Element

Chapter Outline

23-1 Why Carbon?

23-2 Hydrocarbons

23-3 Alcohols, Ethers, and Amines

23-4 Compounds with a Carbonyl Group

23-5 Polymers

THE FOOD OF THE GODS

There is a tree that grows in the tropics called *Theobroma cacao,* a name given to it in 1735 by the Swedish biologist Linnæus. The root of the name comes from the Greek language, meaning "food of the gods."

What could be the "food of the gods"? Chocolate, of course.

The history of chocolate can be traced back to Central America. When the Spanish came to the New World, they discovered cocoa beans were highly prized by the natives—100 beans would purchase a slave in 1500 AD—and that a drink made from the beans was quite delicious. The Spanish explorers first took cocoa to Spain in the late 1500s, and by the 17th century chocolate was popular with the Spanish court.

The appeal of chocolate soon spread to the rest of Europe, and, in the late 1800s two Swiss, Henri Nestlé and Daniel Peter, added dried milk to produce the first milk chocolate.

Chapter Goals

See Chapter Goals Revisited (page 942) for Study Questions keyed to these goals.

UNDERSTAND

- General principles of structure and bonding applied to organic compounds.
- Why carbon forms a vast array of diverse chemical compounds.

DO

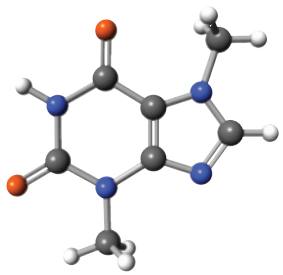
- Classify organic compounds based on formula and structure.
- Recognize and draw structures of structural isomers and stereoisomers for carbon compounds.
- Draw structures of molecules, given the name and/or the formula, and name organic compounds using standard nomenclature rules.
- Predict the products of common organic reactions.
- Identify common polymers.
- Relate properties to molecular structure.

REMEMBER

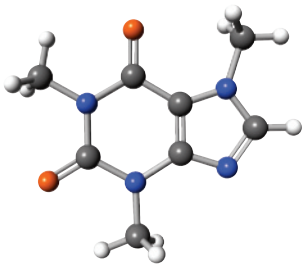
- Common chemical and physical properties of organic compounds.
- Names, structures, and properties of common organic polymers.

This chapter is about organic chemistry, the branch of chemistry that studies molecules based on carbon. Carbon compounds are the basis of all living species on this planet. Chocolate certainly fits into a chapter on organic chemistry, as there are almost 400 organic compounds in chocolate.

A key compound in chocolate is the organic compound theobromine, a bitter alkaloid from the cocoa plant. In spite of the name, there is no bromine in the molecule; its name is derived from the genus of the cocoa plant, *Theobroma*. In medicine, theobromine can be used as a vasodilator, a diuretic, and a heart stimulator. It has even been reputed to be an aphrodisiac! But it can also cause restlessness, tremors, sleeplessness, and anxiety.



Theobromine, $C_7H_8N_4O_2$, one of many molecules in chocolate and a smooth muscle stimulator.



Caffeine, $C_8H_{10}N_4O_2$, like theobromine is a member of a class of compounds called *xanthines*.

Chocolate products usually contain only a few milligrams of theobromine per gram and are quite safe to consume. However, chocolate can be toxic to dogs, and they should not be given chocolate even if they have a sweet tooth.

Theobromine is one of a class of molecules called *xanthines*, a class that includes caffeine. In fact, caffeine is metabolized in the body to theobromine, among other xanthine derivatives.

A Study Question related to this story is: 23.93.

The vast majority of the millions of chemical compounds currently known are organic; that is, they are compounds built on a carbon framework. Organic compounds vary greatly in size and complexity, from the simplest hydrocarbon, methane (CH_4), to molecules made up of many thousands of atoms. As you read this chapter, you will see why the range of possible compounds is huge and why they are so interesting and very often useful.

23-1 Why Carbon?

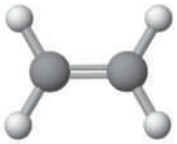
We begin this discussion of organic chemistry with a question: What features of carbon lead to both the abundance and the complexity of organic compounds? The answers to this question revolve around two main issues: structural diversity and stability.

Structural Diversity

With four electrons in its outer shell, carbon will form four bonds to reach an octet configuration. In contrast, the elements boron and nitrogen generally form three bonds in molecular compounds; oxygen forms two bonds; and hydrogen and the halogens form one bond. With a larger number of bonds comes the opportunity to create more complex structures. This will become increasingly evident in this brief tour of organic chemistry.

A carbon atom can reach an octet of electrons in various ways (Figure 23.1):

- *By forming four single bonds*. A carbon atom can bond to four other atoms, which can be either atoms of other elements (often H, N, or O) or other carbon atoms.
- *By forming a double bond and two single bonds*. The carbon atoms in ethylene, $H_2C{=}CH_2$, are linked in this way.
- *By forming two double bonds*, as in carbon dioxide (O=C=O).
- *By forming a triple bond and a single bond*, an arrangement seen in acetylene, HC≡CH.

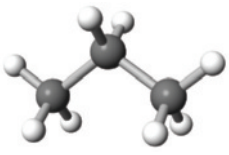


ethene (ethylene), $H_2C{=}CH_2$

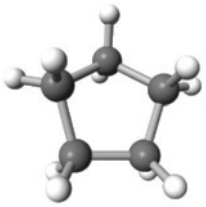
ethyne (acetylene), HC≡CH

Ethylene and acetylene. These two-carbon hydrocarbons can be the building blocks of more complex molecules. These are their common names; their systematic names are ethene and ethyne, respectively.

Recognize, with each of these arrangements, the various possible geometries around carbon: tetrahedral, trigonal-planar, and linear. Carbon's tetrahedral geometry is of special significance because it leads to three-dimensional chains and rings of carbon atoms, as in propane and cyclopentane.



propane, C_3H_8



cyclopentane, C_5H_{10}

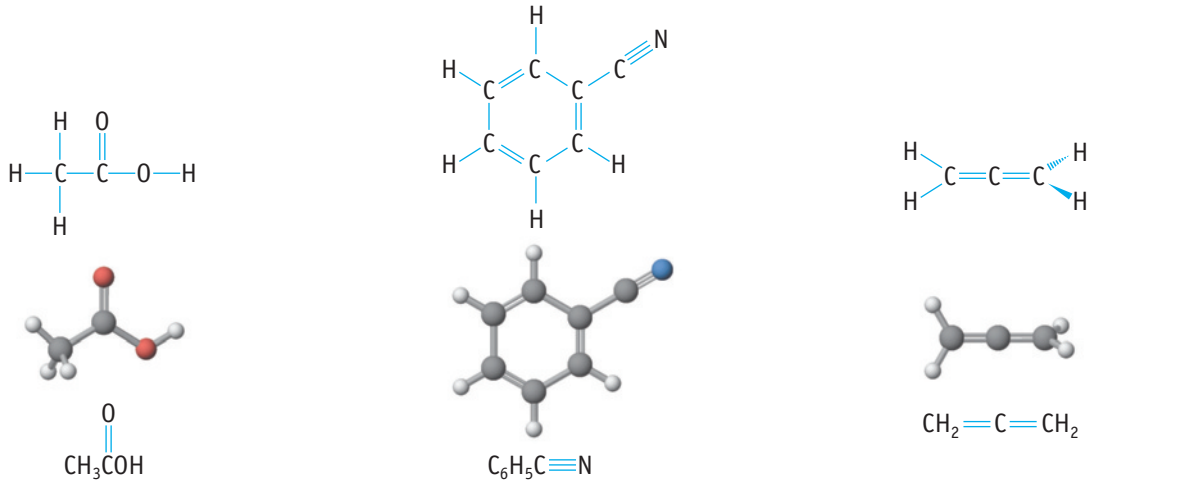
The ability to form multiple bonds leads to families of compounds with double and triple bonds.

Isomers

Isomers are molecules that have the same molecular formula but that have different atom-to-atom connections or that fill space in different ways. A hallmark of carbon chemistry is that there is a remarkable array of isomers, two major groups being structural isomers and stereoisomers.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



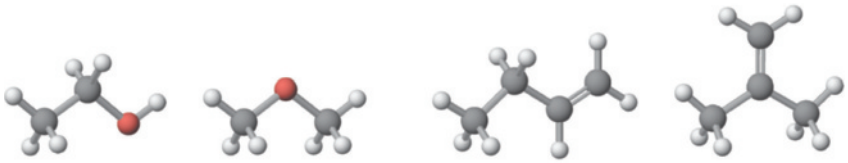
(a) Acetic acid. One carbon atom in this compound is attached to four other atoms by single bonds and has tetrahedral geometry. The second carbon atom, connected by a double bond to one oxygen and by single bonds to the other oxygen and to the first carbon, has trigonal-planar geometry.

(b) Benzonitrile. Six trigonal-planar carbon atoms make up the benzene ring. The seventh C atom, bonded by a single bond to carbon and a triple bond to nitrogen, has a linear geometry.

(c) Carbon is linked by double bonds to two other carbon atoms in C_3H_4, a linear molecule commonly called allene.

FIGURE 23.1 Ways that carbon atoms bond.

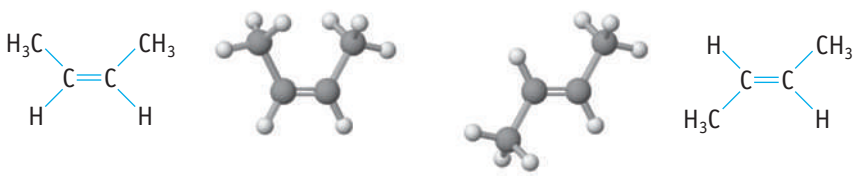
Structural isomers are species with the same elemental composition but the atoms are linked together in different ways. For example, ethanol and dimethyl ether are structural isomers, as are 1-butene and 2-methylpropene.



ethanol	dimethyl ether	1-butene	2-methylpropene
C_2H_6O	C_2H_6O	C_4H_8	C_4H_8
CH_3CH_2OH	CH_3OCH_3	$CH_3CH_2CH{=}CH_2$	$CH_2{=}C(CH_3)CH_3$

Stereoisomers are compounds with the same attachment of atoms but different orientation in space. There are two types of stereoisomers: geometric isomers and optical isomers.

Cis- and *trans*-2-butene are **geometric isomers**. Geometric isomerism in these compounds occurs as a result of the C═C double bond. *Recall that the carbon atom and the attached groups cannot rotate around a double bond* (page 352). Thus, the geometry around the C═C double bond is fixed in space. *Cis–trans* isomerism occurs if each carbon atom involved in the double bond has two different groups attached. If, on the adjacent carbons, it turns out that identical groups are on the same side of the double bond, then it is a *cis* isomer. If those groups appear on opposite sides, a *trans* isomer is produced.



cis-2-butene, C_4H_8 *trans*-2-butene, C_4H_8

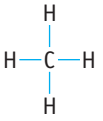
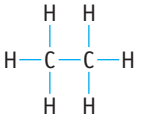
A CLOSER LOOK — Writing Formulas and Drawing Structures

In Chapter 2, you learned that there are various ways of presenting structures (page 65). It is appropriate to return to this topic as we look at organic compounds. Consider methane and ethane, for example. We can represent these molecules in several ways:

1. *Molecular formula:* CH_4 or C_2H_6. This type of formula gives information on composition only.
2. *Condensed formula:* For ethane, this would typically be written CH_3CH_3. This method of writing the formula gives some information on the way atoms are connected.
3. *Structural formula:* You will recognize this formula as the Lewis structure. An elaboration on the condensed formula in (2), this representation defines more clearly how the atoms are connected, but it fails to describe the shapes of molecules.

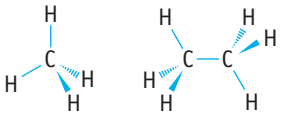


methane, CH_4



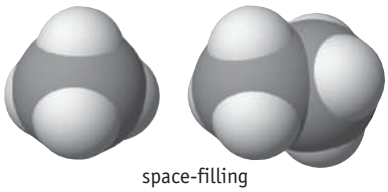
ethane, C_2H_6

4. *Perspective drawings:* These drawings are used to convey the three-dimensional nature of molecules. Bonds extending out of the plane of the paper are drawn with wedges, and bonds behind the plane of the paper are represented as dashed wedges (page 65). Using these guidelines, the structures of methane and ethane could be drawn as follows:



5. *Computer-drawn ball-and-stick and space-filling models.*

ball-and-stick

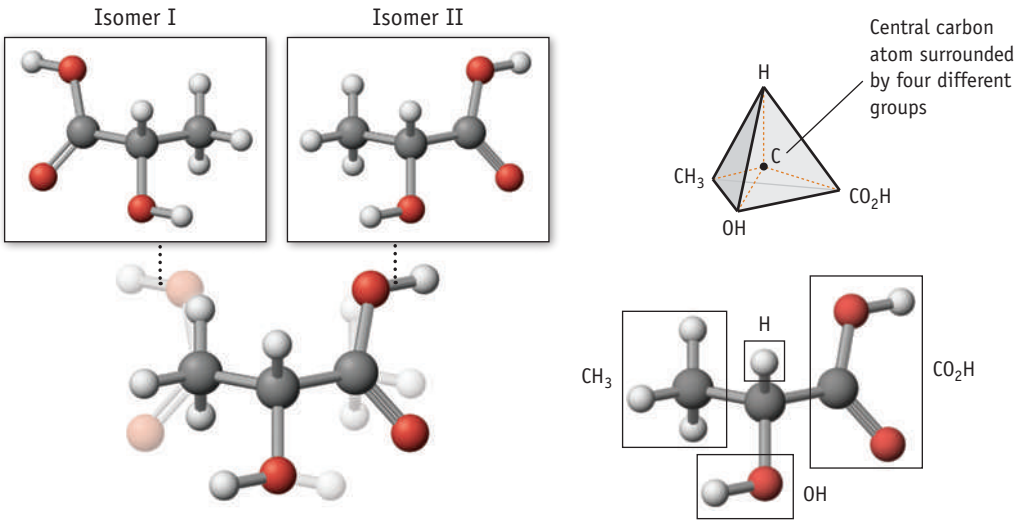


space-filling

Optical isomers are molecules that have nonsuperimposable mirror images (Figure 23.2). Molecules (and other objects) that have nonsuperimposable mirror images are termed **chiral**. Pairs of nonsuperimposable, mirror-image molecules are called **enantiomers**.

Pure samples of enantiomers have the same physical properties, such as melting point, boiling point, density, and solubility in common solvents. They differ in one significant way, however: When a beam of plane-polarized light passes through a solution of a pure enantiomer, the plane of polarization rotates. The two enantiomers rotate polarized light to an equal extent, but in opposite directions (◀ Figure 22.18).

The most common examples of chiral organic compounds are those in which four different atoms (or groups of atoms) are attached to a tetrahedral carbon atom. Lactic acid, found in milk and a product of normal human metabolism, is an example of a chiral compound (Figure 23.2). Optical isomerism is particularly important in



(a) Lactic acid enantiomers are nonsuperimposable, just as your right hand is not superimposable on your left hand.

(b) lactic acid, $CH_3CH(OH)CO_2H$

FIGURE 23.2 Optical isomers. Lactic acid, $CH_3CH(OH)CO_2H$, is produced when milk is fermented to make cheese. It is also found in other sour foods such as sauerkraut and is a preservative in pickled foods such as onions and olives. In our bodies, it is produced by muscle activity and normal metabolism.

One enantiomer of frontalin.

John C. Kotz

An African elephant. Fluid containing the enantiomers of frontalin flows from a gland between the elephant's eye and ear.

FIGURE 23.3 Chirality and elephants. During musth, a time of heightened sexual activity, male elephants produce a secretion containing the enantiomers of frontalin, $C_8H_{14}O_2$. Young males produce more of one enantiomer than the other, whereas older elephants produce a more balanced and more concentrated mixture. The secretion from older elephants repels other males while attracting ovulating female elephants.

amino acids and other biologically important molecules. Among the many interesting examples of optically active compounds is frontalin, produced naturally by male elephants (Figure 23.3).

Chirality and Death Virtually all naturally occurring amino acids, the basis of proteins, are left-handed (see Chapter 24), but right-handed amino acids exist. One such right-handed amino acid has been found to be the toxin in a strain of mushrooms in southern China, and the venom from a bite by a duck-billed platypus is based on a right-handed amino acid. See S. Everts, *Scientific American,* May 2013, pages 78–81.

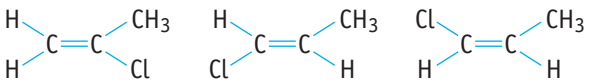
Stability of Carbon Compounds

Carbon compounds are notable for their resistance to chemical change. This resistance is a result of two things: strong bonds and slow reactions.

Strong bonds are needed for molecules to survive in their environment. Energetic collisions between molecules in gases, liquids, and solutions can provide enough energy to break some bonds, and bonds can be broken if the energy associated with photons of visible and ultraviolet light exceeds the bond energy. Carbon–carbon bonds are relatively strong, however, as are the bonds between carbon and most other atoms. The average C—C bond energy is 346 kJ/mol; the C—H bond energy is 413 kJ/mol; and carbon–carbon double and triple bond energies are even higher (◀ Section 8-9). Contrast these values with bond energies for the Si—Si bond (222 kJ/mol) and the Si—H bond (328 kJ/mol). The consequence of high bond energies for bonds to carbon is that, for the most part, organic compounds do not decompose thermally under normal conditions.

Oxidation of most organic compounds is strongly product-favored, but most organic compounds survive continual and prolonged contact with O_2. The reason is that reactions of most organic compounds with oxygen are very slow. Typically, organic compounds burn only if their combustion is initiated by heat or by a spark. As a consequence, oxidative degradation is not a barrier to the existence of organic compounds.

REVIEW & CHECK FOR SECTION 23-1



1. Which pair of the three compounds pictured above are stereoisomers?

   (a) a and b (b) a and c (c) b and c

2. Which pair of compounds are structural isomers?

   (a) a and b (b) b and c

3. How many chiral carbon atoms are there in frontalin (Figure 23.3)?

   (a) 0 (b) 1 (c) 2 (d) 3

Table 23.1 Some Types of Hydrocarbons

Type of Hydrocarbon	Characteristic Features	General Formula	Example
Alkanes	C—C single bonds and all C atoms have four single bonds	C_nH_{2n+2}	CH_4, methane C_2H_6, ethane
Cycloalkanes	C—C single bonds, C atoms arranged in a ring	C_nH_{2n}	C_6H_{12}, cyclohexane
Alkenes	C═C double bond	C_nH_{2n}	$H_2C{=}CH_2$, ethylene
Alkynes	C≡C triple bond	C_nH_{2n-2}	HC≡CH, acetylene
Aromatics	Rings with π bonding extending over several C atoms	—	Benzene, C_6H_6

23-2 Hydrocarbons

Hydrocarbons, compounds made only of carbon and hydrogen, are divided into several subgroups: alkanes, cycloalkanes, alkenes, alkynes, and aromatic compounds (Table 23.1). We begin our discussion by considering alkanes and cycloalkanes, compounds in which each carbon atom is linked with four single bonds to other carbon atoms or to hydrogen.

Alkanes

Petroleum Petroleum is a mixture of alkanes and other hydrocarbons. The petroleum industry is described briefly in Section 20-4.

Alkanes have the general formula C_nH_{2n+2}, with n having integer values (Table 23.2). Formulas of specific compounds can be generated from this formula, the first four of which are CH_4 (methane), C_2H_6 (ethane), C_3H_8 (propane), and C_4H_{10} (butane) (Figure 23.4). Methane has four hydrogen atoms arranged tetrahedrally around a single carbon atom. Replacing a hydrogen atom in methane by a $—CH_3$ group gives ethane. If an H atom of ethane is replaced by yet another $—CH_3$ group, propane results. Butane is derived from propane by replacing an H atom of one of the chain-ending carbon atoms with a $—CH_3$ group. In all of these compounds, each C atom is attached to four other atoms, either C or H, so alkanes are often called **saturated compounds**.

Table 23.2 Selected Hydrocarbons of the Alkane Family, C_nH_{2n+2}*

Name	Molecular Formula	State at Room Temperature
Methane	CH_4	Gas
Ethane	C_2H_6	
Propane	C_3H_8	
Butane	C_4H_{10}	
Pentane	C_5H_{12} (pent- = 5)	Liquid
Hexane	C_6H_{14} (hex- = 6)	
Heptane	C_7H_{16} (hept- = 7)	
Octane	C_8H_{18} (oct- = 8)	
Nonane	C_9H_{20} (non- = 9)	
Decane	$C_{10}H_{22}$ (dec- = 10)	
Octadecane	$C_{18}H_{38}$ (octadec- = 18)	Solid
Eicosane	$C_{20}H_{42}$ (eicos- = 20)	

*This table lists only selected alkanes. At 25 °C straight-chain alkanes with 11–17 C atoms are liquid. Those with more than 17 C atoms are solid.

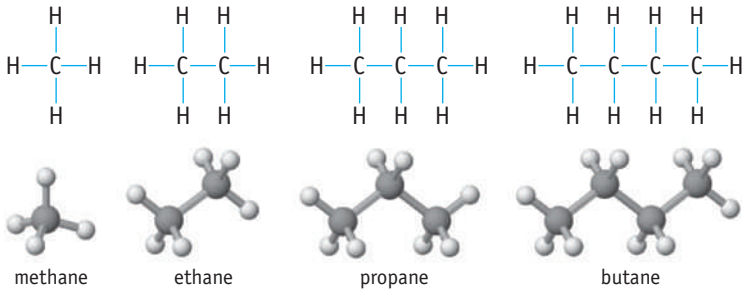

FIGURE 23.4 Alkanes. The lowest–molar-mass alkanes, all gases under normal conditions, are methane, ethane, propane, and butane.

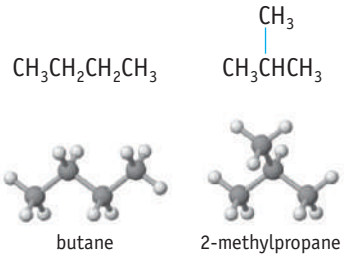
Structural Isomers

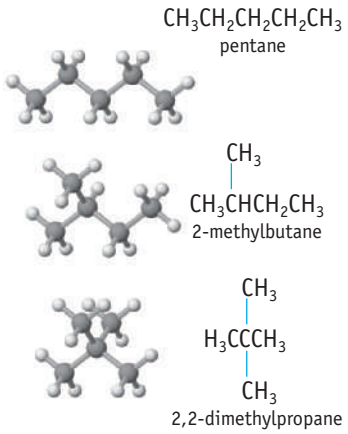
Structural isomers are possible for all alkanes larger than propane. For example, there are two structural isomers for C_4H_{10} and three for C_5H_{12}. As the number of carbon atoms in an alkane increases, the number of possible structural isomers greatly increases; there are five isomers possible for C_6H_{14}, nine isomers for C_7H_{16}, 18 for C_8H_{18}, 75 for $C_{10}H_{22}$, and 1858 for $C_{14}H_{30}$.

To recognize the isomers corresponding to a given formula, keep in mind the following points:

- Each alkane has a framework of tetrahedral carbon atoms, and each carbon has four single bonds.
- An effective approach to deriving isomer structures is to create a framework of carbon atoms and then fill the remaining positions around carbon with H atoms so that each C atom has four bonds.
- Nearly free rotation occurs around carbon–carbon single bonds. Therefore, when atoms are assembled to form the skeleton of an alkane, the emphasis is on how carbon atoms are attached to one another and not on how they might lie relative to one another in the plane of the paper.



Structural isomers of butane, C_4H_{10}



Structural isomers of pentane, C_5H_{12}

EXAMPLE 23.1

Drawing Structural Isomers of Alkanes

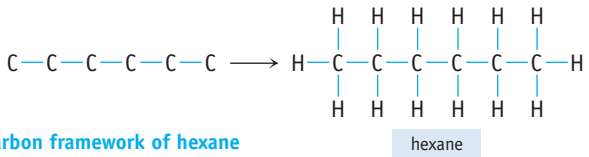
Problem Draw structures of the five isomers of C_6H_{14}. Are any of these isomers chiral?

What Do You Know? Each structure must have six carbon and 14 hydrogen atoms. There must be four single bonds to each carbon atom, and each hydrogen will form one bond.

Strategy Focus first on the different frameworks that can be built from six carbon atoms. Having created a carbon framework, fill hydrogen atoms into the structure so that each carbon has four bonds.

Solution

Step 1. Placing six carbon atoms in a chain gives the framework for the first isomer. Now fill in hydrogen atoms: three on the carbons on the ends of the chain and two on each of the carbons in the middle. You have created the first isomer, hexane.



Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Strategy Map 23.1

PROBLEM

Draw ***structural isomers*** of an **alkane**.

DATA/INFORMATION

- The **formula** is known, so the *longest possible* **C atom chain** is known.

STEP 1. Draw the ***longest*** **C atom chain** possible.

Simplest **straight-chain alkane**

STEP 2. Draw C atom chain ***one atom shorter*** and place a C atom at other places on the chain. Fill in **H** atoms.

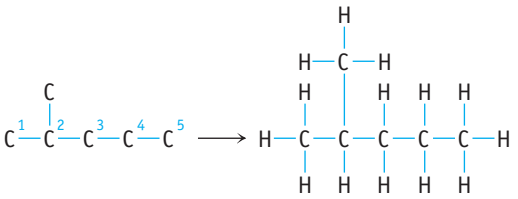
Alkane with **one less C atom** but with ***substituent group*** with **one C atom**

STEP 3. Draw ***shorter chains*** and place remaining C atoms at various positions on the chain.

Remaining isomers

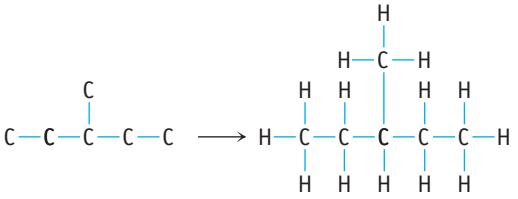
Naming Guidelines For more details on naming organic compounds, see Appendix E.

Step 2. Draw a chain of five carbon atoms, then add the sixth carbon atom to one of the carbon atoms in the middle of this chain. (Adding it to a carbon at the end of the chain gives a six-carbon chain, the same framework drawn in Step 1.) Two different carbon frameworks can be built from the five-carbon chain, depending on whether the sixth carbon is linked to the 2 or 3 position. For each of these frameworks, fill in the hydrogens.



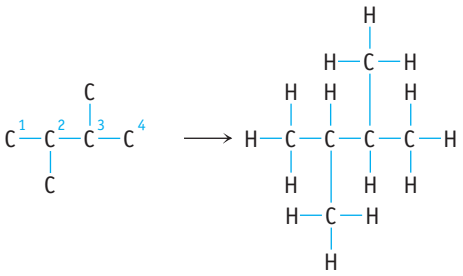
carbon framework of methylpentane isomers

2-methylpentane



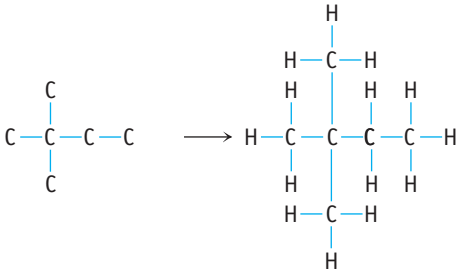
3-methylpentane

Step 3. Draw a chain of four carbon atoms. Add in the two remaining carbons, again being careful not to extend the chain length. Two different structures are possible: one with the remaining carbon atoms in the 2 and 3 positions, and another with both extra carbon atoms attached at the 2 position. Fill in the 14 hydrogens. You have now drawn the fourth and fifth isomers.



carbon atom frameworks for dimethylbutane isomers

2,3-dimethylbutane



2,2-dimethylbutane

None of the isomers of C_6H_{14} is chiral. *To be chiral, a compound must have at least one C atom with four different groups attached.* This condition is not met in any of these isomers.

Think about Your Answer Should we look for structures in which the longest chain is three carbon atoms? Try it, but you will see that it is not possible to add the three remaining carbons to a three-carbon chain without creating one of the carbon chains

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

already drawn in a previous step. Thus, we have completed the analysis, with five isomers of this compound being identified.

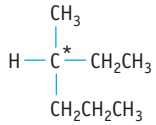
Names have been given to each of these compounds. See the text that follows this Example, and see Appendix E for guidelines on nomenclature.

Check Your Understanding

(a) Draw the nine isomers having the formula C_7H_{16}. (*Hint:* There is one structure with a seven-carbon chain, two structures with six-carbon chains, five structures with a five-carbon chain [one is illustrated in the margin], and one structure with a four-carbon chain.)

(b) Identify the isomers of C_7H_{16} that are chiral.

Chirality in Alkanes To be chiral, *a compound must have at least one C atom attached to four* ***different*** *groups*. Thus, the C_7H_{16} isomer here is chiral.



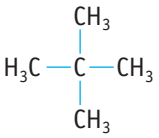
The center of chirality is often indicated with an asterisk.

Naming Alkanes

With so many possible isomers for a given alkane, chemists need a systematic way of naming them. The guidelines for naming alkanes and their derivatives follow:

- The names of alkanes end in "-ane."
- When naming a specific alkane, the root of the name corresponds to the longest carbon chain in the compound. (The names of alkanes with chains of 1 to 10 carbon atoms are given in Table 23.2. After the first four compounds, the names are derived from Greek and Latin numbers—pentane, hexane, heptane, octane, nonane, decane—and this regular naming continues for higher alkanes.)
- Substituent groups on a hydrocarbon chain are identified by a name and the position of substitution in the carbon chain; this information precedes the root of the name. The position is indicated by a number that refers to the carbon atom to which the substituent is attached. Numbering of the carbon atoms in a chain should begin at the end of the carbon chain that allows the first substituent encountered to have the lowest possible number. (If there is no distinction at this point, then number the carbon atoms so that the second substituent group has the lowest number.)
- Names of hydrocarbon substituents, called **alkyl groups**, are derived from the name of the hydrocarbon. The group $—CH_3$, derived by taking a hydrogen from methane, is called the *methyl* group; the $—C_2H_5$ group is the *ethyl* group.
- If two or more of the same substituent groups are present in the molecule, the prefixes di-, tri-, and tetra- are added. When different substituent groups are present, they are generally listed in alphabetical order.

Systematic and Common Names The IUPAC (International Union of Pure and Applied Chemistry) has formulated rules for systematic names, which are generally used in this book (see Appendix). However, many organic compounds are known by common names. For example, 2,2-dimethylpropane is also called neopentane.



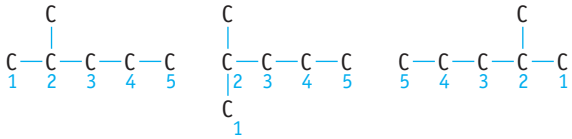
2,2-dimethylpropane

This isomer of C_5H_{12} has a three-carbon chain with two $—CH_3$ groups on the second C atom of the chain. Thus, its name is based on propane, and both $—CH_3$ groups are located at the 2 position.

PROBLEM SOLVING TIP 23.1

Drawing Structural Formulas

An error students sometimes make is to suggest that the three carbon skeletons drawn here are different. They are, in fact, the same. All are five-carbon chains with another C atom in the 2 position.



Remember that Lewis structures do not indicate the geometry of molecules.

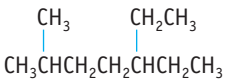
EXAMPLE 23.2

Naming Alkanes

Problem Give the systematic name for



What Do You Know? You know the condensed formula and can recognize that the compound is an alkane. You also know the rules for naming alkanes.

Strategy (a) Identify the longest carbon chain and base the name of the compound on that alkane. (b) Identify the substituent groups on the chain and their locations. (c) When there are two or more substituents (the groups attached to the chain), number the parent chain from the end that gives the lower number to the substituent encountered first. (d) If the substituents are different, list them in alphabetical order.

Solution Here, the longest chain has seven C atoms, so the root of the name is *heptane*. There is a methyl group (—CH_3) on C-2 and an ethyl group (—C_2H_5) on C-5. Giving the substituents in alphabetical order and numbering the chain from the end having the methyl group, the systematic name is 5-ethyl-2-methylheptane.

Think about Your Answer Notice that the carbon atoms in the longest chain are numbered so that the lower number is given to the substituent encountered first.

Check Your Understanding

Name the nine isomers of C_7H_{16} in "Check Your Understanding" in Example 23.1.

FIGURE 23.5 Paraffin wax and mineral oil. These common consumer products are mixtures of alkanes.

Properties of Alkanes

Methane, ethane, propane, and butane are gases at room temperature and pressure, whereas the higher-molar-mass compounds are liquids or solids (see Table 23.2). An increase in melting point and boiling point with molar mass in a series of similar compounds is a general observation (◀ Sections 11-4 and 11-6).

You already know about alkanes in a nonscientific context because several are common fuels. Natural gas, gasoline, kerosene, fuel oils, and lubricating oils are all mixtures of various alkanes. White mineral oil is also a mixture of alkanes, as is paraffin wax (Figure 23.5).

Pure alkanes are colorless and odorless. All are insoluble in water, a property typical of nonpolar compounds. Low polarity is expected for alkanes because the electronegativities of carbon ($\chi = 2.5$) and hydrogen ($\chi = 2.2$) are not greatly different (◀ Section 8-8).

All alkanes burn readily in air to give CO_2 and H_2O in very exothermic reactions. This is, of course, the reason they are widely used as fuels.

$$CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell) \qquad \Delta_r H° = -890.3\ \text{kJ/mol-rxn}$$

Other than in combustion reactions, alkanes exhibit relatively low chemical reactivity. One reaction that does occur, however, is the replacement of the hydrogen atoms of an alkane by chlorine atoms on reaction with Cl_2. It is formally an oxidation because Cl_2, like O_2, is a strong oxidizing agent. These reactions, which can be initiated by ultraviolet radiation, are free radical reactions (◀ Section 14-6). Highly reactive Cl atoms are formed from Cl_2 under ultraviolet (UV) radiation. Reaction of methane with Cl_2 under these conditions proceeds in a series of steps, eventually

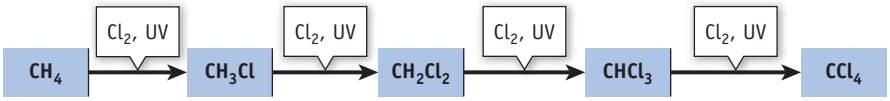
yielding CCl_4, commonly known as carbon tetrachloride. (HCl is the other product of these reactions.)



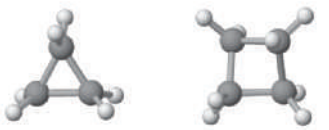
Systematic name:	chloromethane	dichloromethane	trichloromethane	tetrachloromethane
Common name:	methyl chloride	methylene chloride	chloroform	carbon tetrachloride

The last three compounds are used as solvents, albeit infrequently because of their toxicity.

Cycloalkanes, C_nH_{2n}

Cycloalkanes are constructed with tetrahedral carbon atoms joined together to form a ring. Cyclopropane and cyclobutane are the simplest cycloalkanes, although the bond angles in these species are much less than 109.5°. Chemists refer to these compounds as *strained hydrocarbons* because an unfavorable geometry is imposed around carbon. One of the features of strained hydrocarbons is that the C—C bonds are weaker and the molecules readily undergo ring-opening reactions that relieve the bond angle strain.

The most common cycloalkane is cyclohexane, C_6H_{12}, which has a nonplanar ring with six $—CH_2$ groups. If the carbon atoms in this compound were in the form of a regular hexagon with all carbon atoms in one plane, the C—C—C bond angles would be 120°. To have tetrahedral bond angles of 109.5° around each C atom, the ring has to pucker. The C_6 ring is flexible and exists in two interconverting forms (see *A Closer Look: Flexible Molecules*).



cyclopropane, C_3H_6 cyclobutane, C_4H_8

Cyclopropane and cyclobutane. Cyclopropane was at one time used as a general anesthetic in surgery. However, its explosive nature when mixed with oxygen soon eliminated this application.

Alkenes and Alkynes

The diversity seen for alkanes is repeated with **alkenes**, hydrocarbons with one or more C═C double bonds. The presence of a double bond adds two features missing in alkanes: the possibility of geometric isomerism and a higher degree of reactivity.

A CLOSER LOOK — Flexible Molecules

Most organic molecules are flexible; that is, they can twist and bend in various ways. Few molecules better illustrate this behavior than cyclohexane. Two structures are possible: "chair" and "boat" forms, which can interconvert by partial rotation of several bonds.

The more stable structure is the chair form, which allows the hydrogen atoms to remain as far apart as possible. A side view of this form of cyclohexane reveals two sets of hydrogen atoms in this molecule. Six hydrogen atoms, called the *equatorial hydrogens*, lie in a plane around the carbon ring. The other six hydrogens are positioned above and below the plane and are called *axial hydrogens*. Flexing the ring (a rotation around the C—C single bonds) moves the hydrogen atoms between axial and equatorial environments.

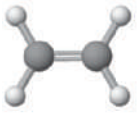
Table 23.3 Properties of Butene Isomers

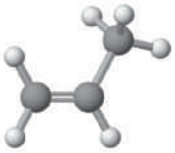
Name	Boiling Point	Melting Point	Dipole Moment (D)	$\Delta_f H°$ (gas) (kJ/mol)
1-Butene	−6.26 °C	−185.4 °C	—	−0.63
2-Methylpropene	−6.95 °C	−140.4 °C	0.503	−17.9
Cis-2-butene	3.71 °C	−138.9 °C	0.253	−7.7
Trans-2-butene	0.88 °C	−105.5 °C	0	−10.8

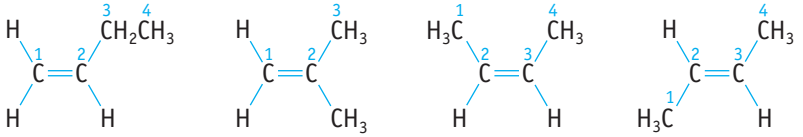
The general formula for alkenes with one double bond is C_nH_{2n}. The first two members of the series are ethene, C_2H_4 (common name, ethylene), and propene, C_3H_6 (common name, propylene). Only a single structure can be drawn for these compounds. As with alkanes, the occurrence of isomers begins with species containing four carbon atoms. Four alkene isomers have the formula C_4H_8, and each has distinct chemical and physical properties (Table 23.3). There are three structural isomers, one of which (2-butene, $CH_3CH{=}CHCH_3$) exists as stereoisomers.

C_2H_4
Systematic name: ethene
Common name: ethylene



C_3H_6
Systematic name: propene
Common name: propylene





Alkene names end in "-ene." As with alkanes, the root for the name of an alkene is determined by the longest carbon chain that contains the double bond. The position of the double bond is indicated with a number, and, when appropriate, the prefix *cis* or *trans* is added.

Three of the C_4H_8 isomers have four-carbon chains and so are butenes. One has a three-carbon chain and is a propene. Notice that the carbon chain is numbered from the end that gives the double bond the lowest number. In the first isomer at the left, the double bond is between C atoms 1 and 2, so the name is 1-butene and not 3-butene.

EXAMPLE 23.3

Determining Isomers of Alkenes from a Formula

Problem Draw structures for the six possible alkene isomers with the formula C_5H_{10}. Give the systematic name of each.

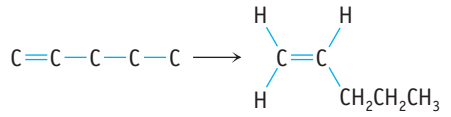
What Do You Know? When linking the five carbon atoms, two will be joined with a double bond. Each carbon must have four bonds, and hydrogen atoms will fill the remaining positions.

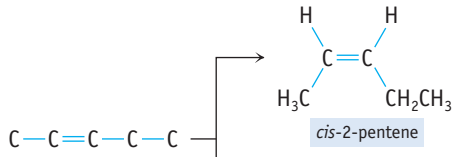
Strategy A procedure that involved drawing the carbon skeleton and then adding hydrogen atoms served well when drawing structures of alkanes (Example 23.1), and a similar approach can be used here. It will be necessary to put one double bond into the framework and to be alert for *cis-trans* isomerism.

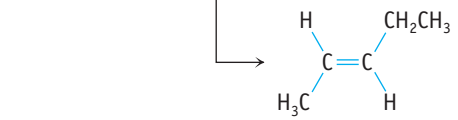
Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Solution

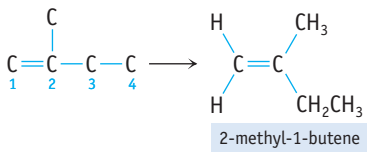
Step 1. A five-carbon chain with one double bond can be constructed in two ways. *Cis–trans* isomers are possible for 2-pentene.

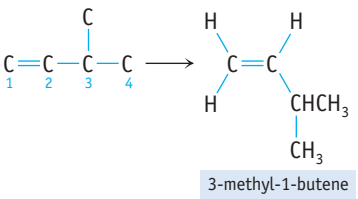


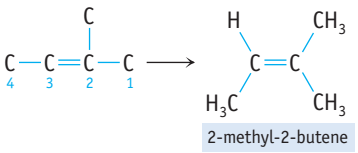




Step 2. Draw the possible four-carbon chains containing a double bond. Add the fifth carbon atom to either the 2 or 3 position. When all the possible combinations are found, fill in the hydrogen atoms. This results in three more structures:







Think about Your Answer It is important to be very organized in your approach when drawing isomers. You should look carefully to see that each structure is unique, that is, that no two are the same.

Check Your Understanding

There are 17 possible alkene isomers with the formula C_6H_{12}. Draw structures of the five isomers in which the longest chain has six carbon atoms, and give the name of each. Are any of these isomers chiral? (There are also eight isomers in which the longest chain has five carbon atoms, and four isomers in which the longest chain has four carbon atoms. How many can you find?)

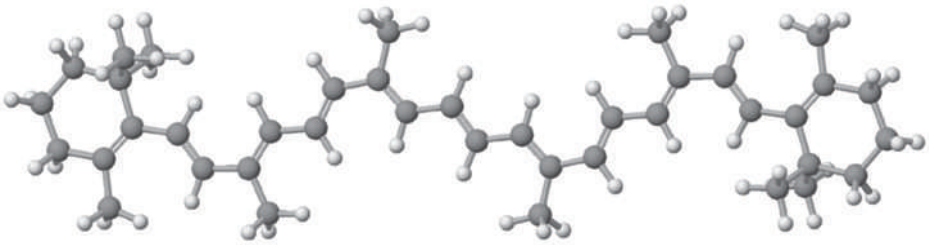

FIGURE 23.6 Carotene, a naturally occurring compound with 11 C═C bonds. The π electrons can be excited by visible light in the blue-violet region of the spectrum. As a result, carotene appears orange-yellow to the observer. Carotene or carotene-like molecules are partnered with chlorophyll in nature in the role of assisting in harvesting sunlight. Green leaves have a high concentration of carotene. In autumn, green chlorophyll molecules are destroyed, and the yellows and reds of carotene and related molecules are seen. The red color of tomatoes, for example, comes from a molecule very closely related to carotene. As a tomato ripens, its chlorophyll disintegrates, and the green color is replaced by the red of the carotene-like molecule.

Hydrocarbons exist that have two or more double bonds. Butadiene, for example, has two double bonds and is known as a *diene*. Many natural products have numerous double bonds (Figure 23.6). There are also cyclic hydrocarbons, such as cyclohexene, with double bonds.

Alkynes, compounds with a carbon–carbon triple bond, have the general formula (C_nH_{2n-2}). Table 23.4 lists alkynes that have four or fewer carbon atoms. The first member of this family is ethyne (common name, acetylene), a gas used as a fuel in metal cutting torches.

Properties of Alkenes and Alkynes

Like alkanes, alkenes and alkynes are colorless. Low–molar-mass compounds are gases, whereas compounds with higher molar masses are liquids or solids. Alkenes and alkynes are also oxidized by O_2 to give CO_2 and H_2O.

Alkenes and alkynes have an elaborate chemistry. We get some insight into their chemical behavior by knowing they are called **unsaturated compounds**. Carbon atoms are capable of bonding to a maximum of four other atoms, and they do so in alkanes and cycloalkanes. In alkenes, however, each carbon atom linked by a double bond is bonded to a total of only three atoms. In alkynes, each carbon atom linked by a triple bond is bonded to a total of only two atoms. It is possible to increase the number of groups attached to a carbon atom in an alkene or alkyne by **addition reactions**, in which molecules with the general formula X—Y (such as hydrogen, halogens, hydrogen halides, and water) add across the carbon–carbon double or

© Cengage Learning/Charles D. Winters

An oxy-acetylene torch. The reaction of ethyne (acetylene) with oxygen produces a very high temperature. Oxy-acetylene torches, used in welding, take advantage of this fact.

Table 23.4 Some Simple Alkynes C_nH_{2n-2}

STRUCTURE	SYSTEMATIC NAME	COMMON NAME	BP (°C)
HC≡CH	ethyne	acetylene	−85
$CH_3C{\equiv}CH$	propyne	methylacetylene	−23
$CH_3CH_2C{\equiv}CH$	1-butyne	ethylacetylene	9
$CH_3C{\equiv}CCH_3$	2-butyne	dimethylacetylene	27

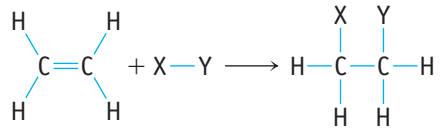
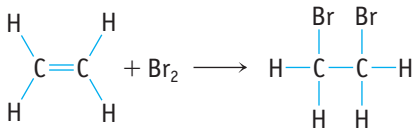
FIGURE 23.7 Bacon fat and addition reactions. The fat in bacon is partially unsaturated. Like other unsaturated compounds, bacon fat reacts with Br_2 in an addition reaction. Here, you see the color of Br_2 vapor fade when a strip of bacon is introduced.

triple bond (Figure 23.7). For an alkene the result is a compound with four groups bonded to each carbon.



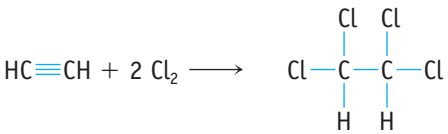
X—Y = H_2, Cl_2, Br_2; H—Cl, H—Br, H—OH, HO—Cl

The products of some addition reactions are substituted alkanes. For example, the addition of bromine to ethene (ethylene) forms 1,2-dibromoethane.



1,2-dibromoethane

The addition of 2 mol of chlorine to ethyne (acetylene) gives 1,1,2,2-tetrachloroethane.

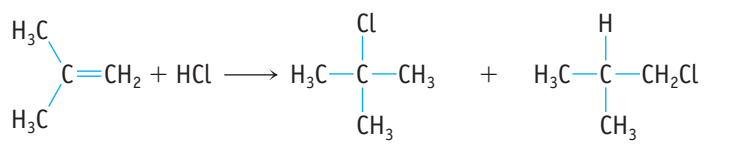


1,1,2,2-tetrachloroethane

Nomenclature of Substituted Alkanes The substituent groups in substituted alkanes are identified by the name and position of the substituent on the alkane chain.

During the 1860s, the Russian chemist Vladimir Markovnikov examined a large number of alkene addition reactions. In cases in which two isomeric products were possible, he found that one was more likely to predominate. Based on these results, Markovnikov formulated a rule (now called *Markovnikov's rule*) stating that, when a reagent HX adds to an unsymmetrical alkene, the hydrogen atom in the reagent becomes attached to the carbon that already has the largest number of hydrogens. An example of Markovnikov's rule is the reaction of 2-methylpropene with HCl that results in formation of 2-chloro-2-methylpropane rather than 1-chloro-2-methylpropane.

Remembering Markovnikov's Rule One of the authors of this book was taught the sentence "Hydrogen goes where hydrogen is." For example, in the reaction of 2-methylpropene, H attaches to the carbon of the $=CH_2$ group.



2-methylpropene

2-chloro-2-methylpropane
sole product

1-chloro-2-methylpropane
not formed

Catalysts A catalyst is a substance that causes a reaction to occur at a faster rate without itself being permanently changed in the reaction (see Section 14-5).

If the reagent added to a double bond is hydrogen (X—Y = H_2), the reaction is called **hydrogenation**. Hydrogenation is usually a very slow reaction, but it can be speeded up by adding a catalyst, often a specially prepared form of a metal, such as platinum, palladium, and rhodium. You may have heard the term *hydrogenation* because certain foods contain "hydrogenated" or "partially hydrogenated" ingredients. One brand of crackers has a label that says, "Made with 100% pure vegetable shortening . . . (partially hydrogenated soybean oil with hydrogenated cottonseed oil)." One reason for hydrogenating an oil is to make it less susceptible to spoilage; another is to convert it from a liquid to a solid.

EXAMPLE 23.4

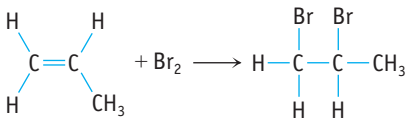
Reaction of an Alkene

Problem Draw the structure of the compound obtained from the reaction of Br_2 with propene, and name the compound.

What Do You Know? Propene is the three-carbon alkene. Addition reactions are among the most common reactions of alkenes, and bromine is one of several common reagents that adds to double bonds.

Strategy Bromine adds across the C═C double bond (Figure 23.7). The name of the product is based on the name of the carbon chain and indicates the positions of the Br atoms.

Solution



propene 1,2-dibromopropane

Think about Your Answer This reaction converts an unsaturated hydrocarbon to a substituted alkane. The reaction product is named as an alkane (propane) with substituents (Br atoms) identified by name and position on the three-carbon chain.

Check Your Understanding

(a) Draw the structure of the compound obtained from the reaction of HBr with ethylene, and name the compound.

(b) Draw the structure of the product of the reaction of Br_2 with *cis*-2-butene, and name this compound.

Aromatic Compounds

Benzene, C_6H_6, is a key molecule in chemistry. It is the simplest **aromatic compound**, a class of compounds so named because they have significant, and usually not unpleasant, odors. Other members of this class, which are all based on benzene, include toluene and naphthalene. A source of many aromatic compounds is coal.

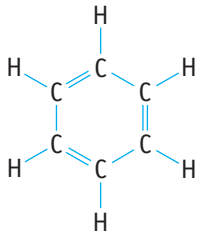
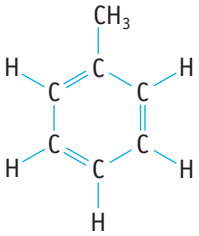
Table 23.5 Some Aromatic Compounds from Coal Tar

Common Name	Formula	Boiling Point (°C)	Melting Point (°C)
Benzene	C_6H_6	80	+6
Toluene	$C_6H_5CH_3$	111	−95
o-Xylene	$1,2\text{-}C_6H_4(CH_3)_2$	144	−25
m-Xylene	$1,3\text{-}C_6H_4(CH_3)_2$	139	−48
p-Xylene	$1,4\text{-}C_6H_4(CH_3)_2$	138	+13
Naphthalene	$C_{10}H_8$	218	+80

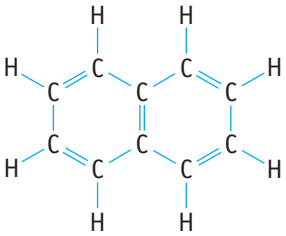
These compounds, along with other volatile substances, are released when coal is heated to a high temperature in the absence of air (Table 23.5).



benzene



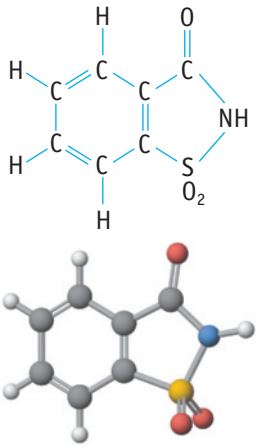
toluene



naphthalene

Benzene occupies a pivotal place in the history and practice of chemistry. Michael Faraday discovered this compound in 1825 as a by-product in the formation of illuminating gas, a fuel produced by heating coal. Today, benzene is an important industrial chemical, usually ranking among the top 25 chemicals in production annually in the United States. It is used as a solvent and is also the starting point for making thousands of different compounds by replacing the H atoms of the ring.

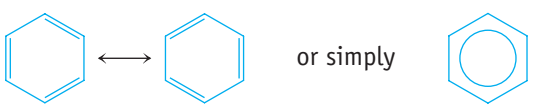
Toluene was originally obtained from tolu balsam, the pleasant-smelling gum of a South American tree, *Toluifera balsamum*. This balsam has been used in cough syrups and perfumes. Naphthalene is an ingredient in "moth balls," although 1,4-dichlorobenzene is now more commonly used. Aspartame and another artificial sweetener, saccharin, are also benzene derivatives.



Saccharin ($C_7H_5NO_3S$). This compound, an artificial sweetener, contains an aromatic ring.

The Structure of Benzene

The formula of benzene suggested to 19th-century chemists that this compound should be unsaturated, but, if viewed this way, its chemistry was perplexing. Whereas alkenes readily undergo addition reactions, benzene does not do so under similar conditions. We now recognize that benzene's different reactivity relates to its structure and bonding, both of which are quite different from the structure and bonding in alkenes. Benzene has six equivalent carbon–carbon bonds, 139 pm in length, intermediate between a C—C single bond (154 pm) and a C=C double bond (134 pm). The π bonds are formed by the continuous overlap of the p orbitals on the six carbon atoms (◀ Section 9-2). Using valence bond terminology, the structure is represented by two resonance structures.



representations of benzene, C_6H_6

Drawing Aromatic Rings When drawing benzene rings chemists often allow the vertices of the hexagon to represent the carbon atoms and do not show the H atoms attached to those carbon atoms. The circle inside the ring indicates the two resonance structures.

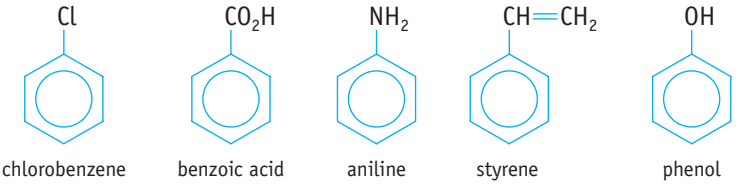
© INTERFOTO/Alamy

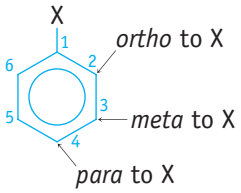
August Kekulé and the Structure of Benzene The structural question was solved by August Kekulé (1829–1896). Kekulé, one of the most prominent organic chemists in Europe in the late 19th century, argued for the ring structure with alternating double bonds based on the number of isomers possible for the structure. The legend in chemistry is that Kekulé proposed the ring structure after dreaming of a snake biting its tail.

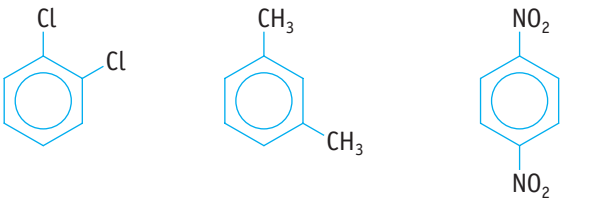
Benzene Derivatives

Toluene, chlorobenzene, benzoic acid, aniline, styrene, and phenol are common examples of benzene derivatives.



The systematic nomenclature for benzene derivatives with two or more substituent groups involves naming these groups and identifying their positions on the ring by numbering the six carbon atoms (▶ Appendix E). Some common names, which are based on an older naming scheme, are also used. This scheme identified isomers of disubstituted benzenes with the prefixes *ortho* (*o*-, substituent groups on adjacent carbons in the benzene ring), *meta* (*m*-, substituents separated by one carbon atom), and *para* (*p*-, substituent groups on carbons on opposite sides of the ring).





Systematic name:	1,2-dichlorobenzene	1,3-dimethylbenzene	1,4-dinitrobenzene
Common name:	*o*-dichlorobenzene	*m*-xylene	*p*-dinitrobenzene

EXAMPLE 23.5

Isomers of Substituted Benzenes

Problem Draw and name the isomers of $C_6H_3Cl_3$.

What Do You Know? From the formula you can infer that $C_6H_3Cl_3$ is a substituted benzene with three hydrogen atoms replaced by chlorine atoms.

Strategy Begin by drawing the carbon framework of benzene, and attach a chlorine atom to one of the carbon atoms. Place a second Cl atom on the ring in the *ortho, meta,* and *para* positions. Add the third Cl in one of the remaining positions, being careful not to repeat a structure already drawn.

Solution The three isomers of $C_6H_3Cl_3$ are shown here. They are named as derivatives of benzene by specifying the number of substituent groups with the prefix "tri-," the name of the substituent, and the positions of the three groups around the six-member ring.

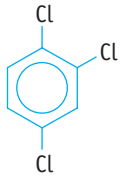
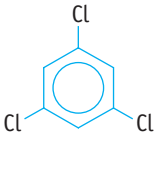
1,2,3-trichlorobenzene



1,2,4-trichlorobenzene



1,3,5-trichlorobenzene

Think about Your Answer Are there other possibilities? Try moving the chlorine atoms around in each isomer. In every case, you will find that moving one Cl atom to a different position generates one of these three isomers. For example, in the first structure, moving the Cl atom at position 1 to either position 5 or 6 leads to the second structure.

Check Your Understanding

Aniline, $C_6H_5NH_2$, is the common name for aminobenzene. Draw a structure for *p*-diaminobenzene, a compound used in dye manufacture. What is the systematic name for *p*-diaminobenzene?

Properties of Aromatic Compounds

Benzene is a colorless liquid, and simple substituted benzenes are liquids or solids under normal conditions. The properties of aromatic hydrocarbons are typical of hydrocarbons in general: They are insoluble in water, soluble in nonpolar solvents, and are oxidized by O_2 to form CO_2 and H_2O.

One of the most important properties of benzene and other aromatic compounds is an unusual stability that is associated with the unique π bonding in this molecule (◀ Section 9-2 and Figure 9.12). Because the π bonding in benzene is typically described using resonance structures, the extra stability is termed **resonance stabilization**. The extent of resonance stabilization in benzene is evaluated by comparing the energy evolved in the hydrogenation of benzene to form cyclohexane

$$C_6H_6(\ell) + 3\ H_2(g) \xrightarrow{\text{catalyst}} C_6H_{12}(\ell) \qquad \Delta_r H° = -206.7\ \text{kJ/mol-rxn}$$

with the energy evolved in hydrogenation of three isolated double bonds.

$$3\ H_2C{=}CH_2(g) + 3\ H_2(g) \rightarrow 3\ C_2H_6(g) \qquad \Delta_r H° = -410.8\ \text{kJ/mol-rxn}$$

The hydrogenation of benzene is about 200 kJ/mol less exothermic than the hydrogenation of three moles of ethene, a difference attributable to the added stability associated with π bonding in benzene.

Although aromatic compounds are unsaturated hydrocarbons, they do not undergo the addition reactions typical of alkenes and alkynes. Instead, *substitution reactions* occur, in which one or more hydrogen atoms are replaced by other groups. Such reactions require higher temperatures and a strong Brønsted acid such as H_2SO_4 or a Lewis acid such as $AlCl_3$ or $FeBr_3$.

$$\textit{Nitration:}\quad C_6H_6(\ell) + HNO_3(\ell) \xrightarrow{H_2SO_4} C_6H_5NO_2(\ell) + H_2O(\ell)$$

$$\textit{Alkylation:}\quad C_6H_6(\ell) + CH_3Cl(\ell) \xrightarrow{AlCl_3} C_6H_5CH_3(\ell) + HCl(g)$$

$$\textit{Halogenation:}\quad C_6H_6(\ell) + Br_2(\ell) \xrightarrow{FeBr_3} C_6H_5Br(\ell) + HBr(g)$$

Lewis Acids G. N. Lewis (page 285) defined an acid as an electron-pair acceptor (such as $AlCl_3$ and BF_3) (see Section 16-10).

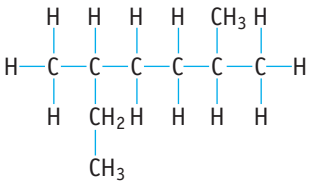
REVIEW & CHECK FOR SECTION 23-2

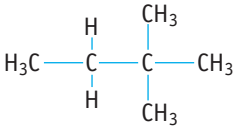
1. What is the systematic name for this alkane?



(a) nonane (c) 2, 5-dimethylheptane

(b) 2-ethyl-5-methylhexane (d) dimethyloctane

2. Which statement below correctly describes the following compound?



(a) The compound is an isomer of pentane, is chiral, and is named 2,3-dimethylbutane.

(b) The compound is an isomer of octane, is not chiral, and is named 2,2-dimethylbutane.

(c) The compound is an isomer of hexane, is not chiral, and is named 2,2-dimethylbutane.

(d) The compound is an isomer of hexane, is not chiral, and is named 3,3-dimethylbutane.

3. Consider the following list of compounds:

1. C_2H_4 2. C_5H_{10} 3. $C_{14}H_{30}$ 4. C_7H_8

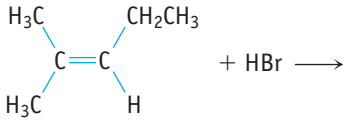
(i) Which compound or compounds in the list can be an (non-cyclic) alkane?

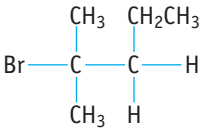
(a) only 1 (b) 2 and 3 (c) only 3 (d) 3 and 4

(ii) Which compound or compounds in the list can be an alkene?

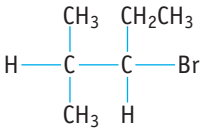
(a) only 1 (b) only 2 (c) 1 and 2 (d) 3 and 4

4. What is the product of the following reaction?





(a)



(b)

5. How many isomers are possible for $C_6H_4(CH_3)Cl$, a benzene derivative?

(a) 1 (b) 2 (c) 3

Table 23.6 Common Functional Groups and Derivatives of Alkanes

Functional Group*	General Formula*	Class of Compound	Examples
F, Cl, Br, I	RF, RCl, RBr, RI	Haloalkane	CH_3CH_2Cl, chloroethane
OH	ROH	Alcohol	CH_3CH_2OH, ethanol
OR′	ROR′	Ether	$(CH_3CH_2)_2O$, diethyl ether
NH_2†	RNH_2	(Primary) Amine	$CH_3CH_2NH_2$, ethylamine
$-\overset{\overset{O}{\|}}{C}H$	RCHO	Aldehyde	CH_3CHO, ethanal (acetaldehyde)
$-\overset{\overset{O}{\|}}{C}-R'$	RCOR′	Ketone	CH_3COCH_3, propanone (acetone)
$-\overset{\overset{O}{\|}}{C}-OH$	RCO_2H	Carboxylic acid	CH_3CO_2H, ethanoic acid (acetic acid)
$-\overset{\overset{O}{\|}}{C}-OR'$	RCO_2R'	Ester	$CH_3CO_2CH_3$, methyl acetate
$-\overset{\overset{O}{\|}}{C}-NH_2$	$RCONH_2$	Amide	CH_3CONH_2, acetamide

*R and R′ can be the same or different hydrocarbon groups.
†Secondary amines (R_2NH) and tertiary amines (R_3N) are also possible, see discussion in the text.

23-3 Alcohols, Ethers, and Amines

Organic compounds often contain other elements in addition to carbon and hydrogen. Two elements in particular, oxygen and nitrogen, add a rich dimension to carbon chemistry.

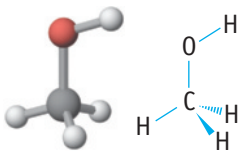
Organic chemistry organizes compounds containing elements other than carbon and hydrogen as derivatives of hydrocarbons. Formulas (and structures) are represented by substituting one or more hydrogens in a hydrocarbon molecule by a **functional group**. A functional group is an atom or group of atoms attached to a carbon atom in the hydrocarbon. Formulas of hydrocarbon derivatives are then written as R—X, in which R is a hydrocarbon lacking a hydrogen atom, and X is the functional group (such as —OH, $—NH_2$, a halogen atom, or $—CO_2H$) that has replaced the hydrogen. The chemical and physical properties of the hydrocarbon derivatives are a blend of the properties associated with hydrocarbons and the group that has been substituted for hydrogen.

Table 23.6 identifies some common functional groups and the families of organic compounds resulting from their attachment to a hydrocarbon.

Alcohols and Ethers

If one of the hydrogen atoms of an alkane is replaced by a hydroxyl (—OH) group, the result is an **alcohol**, ROH. Methanol, CH_3OH, and ethanol, CH_3CH_2OH, are the most important alcohols, but others are also commercially important (Table 23.7). Notice that several have more than one OH functional group.

More than 5×10^8 kg of methanol is produced in the United States annually. Most of this is used to make formaldehyde (CH_2O) and acetic acid (CH_3CO_2H), both important chemicals in their own right. Methanol is also used as a solvent, as a de-icer in gasoline, and as a fuel in high-powered racing cars. It is found in low concentration in new wine, where it contributes to the odor, or "bouquet." Like



Methanol, CH_3OH, the simplest alcohol. Methanol is often called *wood alcohol* because it was originally produced by heating wood in the absence of air.

Rubbing alcohol. Common rubbing alcohol is 2-propanol, also called *isopropyl alcohol.*

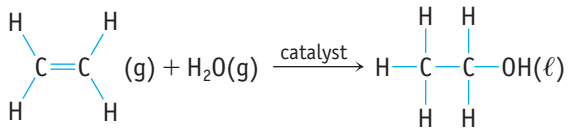
Table 23.7 Some Important Alcohols

Condensed Formula	BP (°C)	Systematic Name	Common Name	Use
CH_3OH	65.0	Methanol	Methyl alcohol	Fuel, gasoline additive, making formaldehyde
CH_3CH_2OH	78.5	Ethanol	Ethyl alcohol	Beverages, gasoline additive, solvent
$CH_3CH_2CH_2OH$	97.4	1-Propanol	Propyl alcohol	Industrial solvent
$CH_3CH(OH)CH_3$	82.4	2-Propanol	Isopropyl alcohol	Rubbing alcohol
$HOCH_2CH_2OH$	198	1,2-Ethanediol	Ethylene glycol	Antifreeze
$HOCH_2CH(OH)CH_2OH$	290	1,2,3-Propanetriol	Glycerol (glycerin)	Moisturizer in consumer products

ethanol, methanol causes intoxication, but methanol differs in being more poisonous, largely because the human body converts it to formic acid (HCO_2H) and formaldehyde (CH_2O). These compounds attack the cells of the retina in the eye, leading to permanent blindness.

Ethanol is the "alcohol" of alcoholic beverages, in which it is formed by the anaerobic (without air) fermentation of sugar. On a much larger scale, ethanol for use as a fuel is made by fermentation of corn and other plant materials. Some ethanol (about 5%) is made from petroleum, by the reaction of ethylene and water.

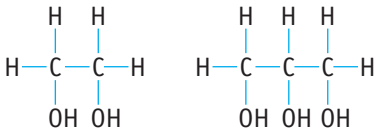
Naming Alcohols Substitute "-ol" for the final "-e" in the name of the hydrocarbon, and designate the position of the —OH group by the number of the carbon atom. For example, $CH_3CH_2CHOHCH_3$ is named as a derivative of butane. The —OH group is attached to the second carbon, so the name is 2-butanol.



ethylene ethanol

Beginning with three-carbon alcohols, structural isomers are possible. For example, 1-propanol and 2-propanol (common names, propyl alcohol and isopropyl alcohol) are different compounds (Table 23.7).

Ethylene glycol and glycerol are common alcohols having two and three —OH groups, respectively. Ethylene glycol is used as antifreeze in automobiles. Glycerol's most common use is as a softener in soaps and lotions. It is also a raw material for the preparation of nitroglycerin (Figure 23.8).



Systematic name: 1,2-ethanediol 1,2,3-propanetriol
Common name: ethylene glycol glycerol or glycerin

Ethers have the general formula ROR′. The best-known ether is diethyl ether, $CH_3CH_2OCH_2CH_3$. Lacking an —OH group, the properties of ethers are in sharp contrast to those of alcohols. Diethyl ether, for example, has a lower boiling point (34.5 °C) than ethanol, CH_3CH_2OH (78.3 °C), and is only slightly soluble in water.

EXAMPLE 23.6

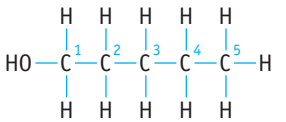
Structural Isomers of Alcohols

Problem How many different alcohols with one —OH group are derivatives of pentane? Draw their structures, and name each alcohol.

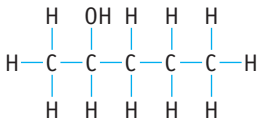
What Do You Know? The formula for pentane is C_5H_{12}. In an alcohol an —OH group will replace one H atom.

Strategy Pentane, C_5H_{12}, has a five-carbon chain. An —OH group can replace a hydrogen atom on one of the carbon atoms. Alcohols are named as derivatives of the alkane (pentane) by replacing the "-e" at the end with "-ol" and indicating the position of the —OH group by a numerical prefix (Appendix E).

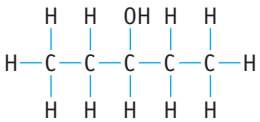
Solution Three different alcohols are possible, depending on whether the —OH group is placed on the first, second, or third carbon atom in the chain. (The fourth and fifth positions are identical to the second and first positions in the chain, respectively.)



1-pentanol



2-pentanol



3-pentanol

Think about Your Answer Additional structural isomers with the formula $C_5H_{11}OH$ are possible in which the longest carbon chain has three C atoms (one isomer) or four C atoms (four isomers).

Check Your Understanding

Draw the structure of 1-butanol and alcohols that are structural isomers of the compound.

Properties of Alcohols

Methane, CH_4, is a gas (boiling point, −161 °C) with low solubility in water. Methanol, CH_3OH, by contrast, is a liquid that is *miscible* with water in all proportions. The boiling point of methanol, 65 °C, is 226 °C higher than the boiling point of methane. What a difference the addition of a single atom into the structure can make in the properties of simple molecules!

Alcohols are related to water, with one of the H atoms of H_2O being replaced by an organic group. If a methyl group is substituted for one of the hydrogens of water, methanol results. Ethanol has a $—C_2H_5$ (ethyl) group, and propanol has a $—C_3H_7$ (propyl) group in place of one of the hydrogens of water. Viewing alcohols as related to water also helps in understanding their properties.

The two parts of methanol, the $—CH_3$ group and the —OH group, contribute to its properties. For example, methanol will burn, a property associated with hydrocarbons. On the other hand, its boiling point is more like that of water. The temperature at which a substance boils is related to the forces of attraction between molecules, called *intermolecular forces:* The stronger the attractive, intermolecular forces in a sample, the higher the boiling point (◀ Section 11-3). These forces are particularly strong in water, a result of the polarity of the —OH group in this molecule (◀ Section 8-8). Methanol is also a polar molecule, and it is the polar —OH group that leads to a high boiling point. In contrast, methane is nonpolar and its low boiling point is the result of weak intermolecular forces.

It is also possible to explain the differences in the solubility of methane, methanol, and other alcohols in water (Figure 23.9). The solubility of methanol and ethylene glycol is conferred by the polar —OH portion of the molecule. Methane, which is nonpolar, has low water solubility.

As the size of the alkyl group in an alcohol increases, the alcohol boiling point rises, a general trend seen in families of similar compounds and related to molar mass (see Table 23.7). The solubility in water in this series decreases. Methanol and ethanol are completely miscible in water, whereas 1-propanol is moderately water soluble; 1-butanol is less soluble than 1-propanol. With an increase in the size of the hydrocarbon group, the organic group (the nonpolar part of the molecule) has become a larger fraction of the molecule, and properties associated with nonpolarity begin to dominate. Space-filling models show that in methanol, the polar and

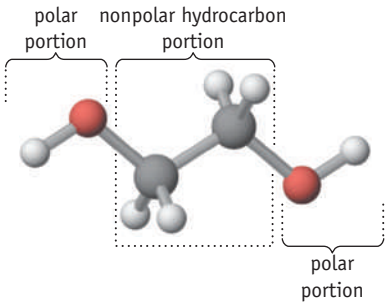
Methanol is often added to automobile gasoline tanks in the winter to prevent water in the fuel lines from freezing. It is soluble in water and lowers the water's freezing point.



Ethylene glycol is used in automobile radiators. It is soluble in water, and lowers the freezing point and raises the boiling point of the water in the cooling system. (▶ Section 14-4.)

Ethylene glycol, a major component of automobile antifreeze, is completely miscible with water.

FIGURE 23.9 Properties and uses of two alcohols, methanol and ethylene glycol.

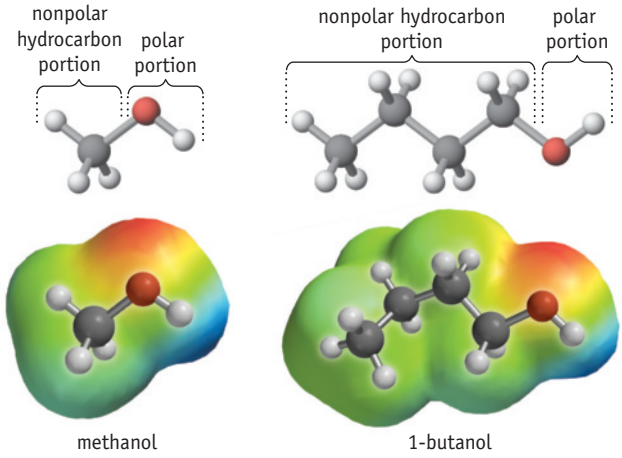
nonpolar parts of the molecule are approximately similar in size, but in 1-butanol the —OH group is less than 20% of the molecule. The molecule is less like water and more "organic." Electrostatic potential surfaces amplify this point.

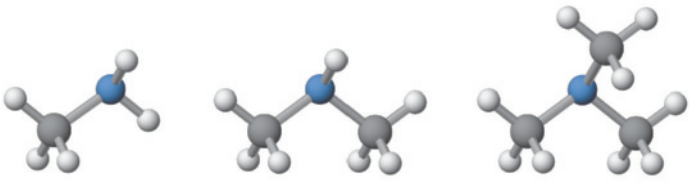


Amines

It is often convenient to think about water and ammonia as being similar molecules: They are the simplest hydrogen compounds of adjacent second-period elements. Both are polar and exhibit some similar chemistry, such as protonation (to give H_3O^+ and NH_4^+) and deprotonation (to give OH^- and NH_2^-).

This comparison of water and ammonia can be extended to alcohols and amines. Alcohols have formulas related to water in which one hydrogen in H_2O is replaced with an organic group (R—OH). In organic **amines**, one or more hydrogen atoms of NH_3 are replaced with an organic group. Amine structures are similar to ammonia's structure; that is, the geometry about the N atom is trigonal pyramidal.

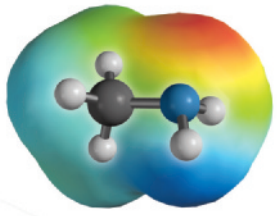
Amines are categorized based on the number of organic substituents as *primary* (one organic group), *secondary* (two organic groups), or *tertiary* (three organic groups). As examples, consider the three amines with methyl groups: CH_3NH_2, $(CH_3)_2NH$, and $(CH_3)_3N$.



CH_3NH_2
primary amine
methylamine

$(CH_3)_2NH$
secondary amine
dimethylamine

$(CH_3)_3N$
tertiary amine
trimethylamine



Electrostatic potential surface for methylamine. The surface for methyl-amine shows that this water-soluble amine is polar with the partial negative charge on the N atom.

Properties of Amines

Amines usually have offensive odors. You know what the odor is if you have ever smelled decaying fish. Two appropriately named amines, putrescine and cadaverine, add to the odor of urine, rotten meat, and bad breath.

$H_2NCH_2CH_2CH_2CH_2NH_2$
putrescine
1,4-butanediamine

$H_2NCH_2CH_2CH_2CH_2CH_2NH_2$
cadaverine
1,5-pentanediamine

The smallest amines are water soluble, but most amines are not. All amines are bases, however, and they react with acids to give salts, many of which are water

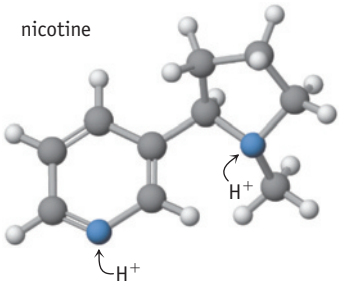
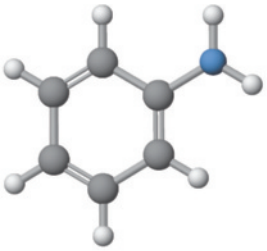
nicotine



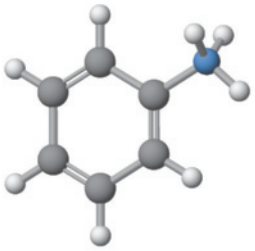
Nicotine, an amine. Two nitrogen atoms in the nicotine molecule can be protonated, which is the form in which nicotine is normally found. The protons can be removed, by treating it with a base. This "free-base" form is much more poisonous and addictive.

soluble. As with ammonia, the reactions involve adding H^+ to the lone pair of electrons on the N atom. This is illustrated by the reaction of aniline (aminobenzene) with H_2SO_4 to give anilinium hydrogen sulfate.

$$C_6H_5NH_2(aq) + H_2SO_4(aq) \longrightarrow C_6H_5NH_3^+(aq) + HSO_4^-(aq)$$



aniline



anilinium ion

The facts that an amine can be protonated and that the proton can be removed again by treating the compound with a base have practical and physiological importance. Nicotine in cigarettes is normally found in the protonated form. (This water-soluble form is also used often in insecticides.) Adding a base such as ammonia removes the H^+ ion to leave nicotine in its "free-base" form.

$$NicH_2^{2+}(aq) + 2\ NH_3(aq) \rightarrow Nic(aq) + 2\ NH_4^+(aq)$$

In this form, nicotine is much more readily absorbed by the skin and mucous membranes, so the compound is a much more potent poison.

REVIEW & CHECK FOR SECTION 23-3

1. How many different compounds (alcohols and ethers) exist with the molecular formula $C_4H_{10}O$?

   (a) 2 (b) 3 (c) 4 (d) more than 4

2. Which of the following compounds is not chiral, that is, which does not possess a carbon atom attached to four different groups?

   (a) 2-propanol (c) 2-methyl-3-pentanol

   (b) 2-butanol (d) 1,2-propanediol

3. What is the hybridization of nitrogen in dimethylamine?

   (a) sp^3 (c) sp

   (b) sp^2 (d) nitrogen is not hybridized

CASE STUDY An Awakening with L-DOPA

From about 1917 to 1928, millions of people worldwide were affected by a condition known as *encephalitis lethargica*, a form of sleeping sickness. Those who suffered from the condition were in a state of semi-consciousness that lasted for decades. In his book *Awakenings*, Oliver Sacks wrote about treating a patient with the compound L-DOPA, which "was started in early March 1969 and raised by degrees to 5.0 g a day. Little effect was seen for two weeks, and then a sudden 'conversion' took place. . . . Mr. L enjoyed a mobility, a health, and a happiness which he had not known in thirty years. Everything about him filled with delight: he was like a man who had awoken from a nightmare or a serious illness. . . ."

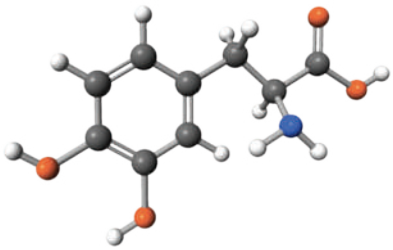
COLUMBIA/THE KOBAL COLLECTION/ GOLDMAN, LOUIS

Robert DeNiro as Leonard Lowe and Robin Williams as Malcolm Sayer, a fictionalized portrayal of Oliver Sacks, in the movie version of *Awakenings*.

If you have read the book or have seen the movie of the same name, you know that Mr. L eventually could not tolerate the treatment, but that Sacks treated many others who benefitted from it. L-DOPA is now widely used in the treatment of another condition, Parkinson's disease, a degenerative disorder of the central nervous system.

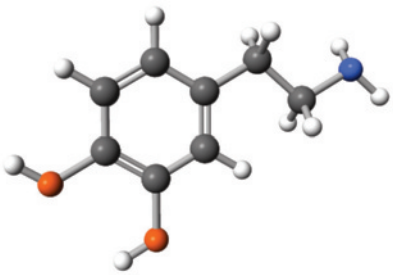
L-DOPA or L-dopamine (L-3,4-dihydroxy–phenylalanine) is chiral. The symbol L stands for "levo," which means a solution of the compound rotates polarized light to the left. The compound is also a derivative of phenylalanine, one of many naturally occurring alpha-amino acids that play such an important role in protein formation and other natural processes.

L-DOPA also illustrates why chiral molecules are so interesting to chemists: Only the "levo" enantiomer is physiologically active. The enantiomer that rotates polarized light in the opposite direction has no biological function.



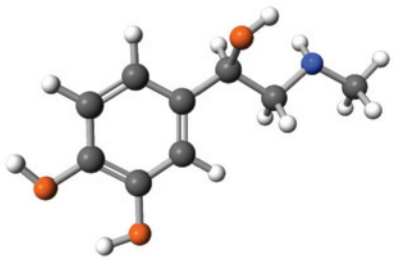
L-DOPA, $C_9H_{11}NO_4$,
a treatment for Parkinson's disease

When L-DOPA is ingested, it is metabolized to dopamine in a process that removes the carboxylic acid group, $—CO_2H$, and it is dopamine that is physiologically active. Dopamine is a neurotransmitter that occurs in a wide variety of animals.



dopamine, $C_8H_{11}NO_2$, a neurotransmitter

Interestingly, both L-DOPA and dopamine are closely related to another amine, epinephrine. This is sometimes referred to as adrenaline, the hormone that is released from the adrenal glands when there is an emergency or danger threatens.



epinephrine or adrenaline, $C_9H_{13}NO_3$

Questions:

1. L-DOPA is chiral. What is the center of chirality in the molecule?
2. Is either dopamine or epinephrine chiral? If so, what is the center of chirality?
3. If you are treated with 5.0 g of L-DOPA, what amount (in moles) is this?

Answers to these questions are available in Appendix N.

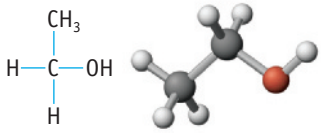
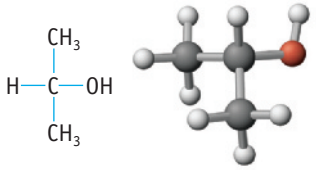
In this section, we will examine five groups of carbonyl compounds (see Table 23.6):

- *Aldehydes* (RCHO) have an organic group (—R) and an H atom attached to a carbonyl group.
- *Ketones* (RCOR′) have two —R groups attached to the carbonyl carbon; they may be the same groups, as in acetone, or different groups.
- *Carboxylic acids* (RCO_2H) have an —R group and an —OH group attached to the carbonyl carbon.
- *Esters* (RCO_2R') have —R and —OR′ groups attached to the carbonyl carbon.
- *Amides* ($RCONR_2'$, RCONHR′, and $RCONH_2$) have an —R group and an amino group ($—NH_2$, —NHR, $—NR_2$) bonded to the carbonyl carbon.

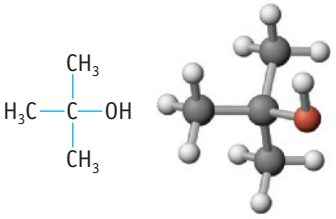
Primary alcohol: ethanol



Secondary alcohol: 2-propanol

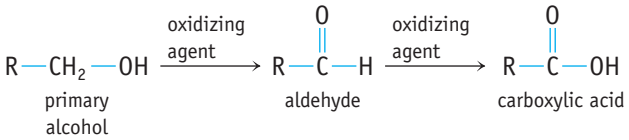


Tertiary alcohol: 2-methyl-2-propanol

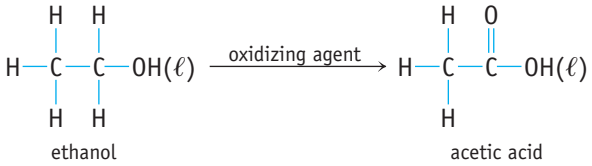


Aldehydes, ketones, and carboxylic acids are oxidation products of alcohols and, indeed, are commonly made by this route. The product obtained through oxidation of an alcohol depends on the alcohol's structure, which is classified according to the number of carbon atoms bonded to the C atom bearing the —OH group. *Primary alcohols* have one carbon and two hydrogen atoms attached, whereas *secondary alcohols* have two carbon atoms and one hydrogen atom attached. *Tertiary alcohols* have three carbon atoms attached to the C atom bearing the —OH group.

A *primary alcohol* is oxidized in two steps, first to an aldehyde and then to a carboxylic acid:



For example, the air oxidation of ethanol in wine produces wine vinegar, the most important ingredient of which is acetic acid.

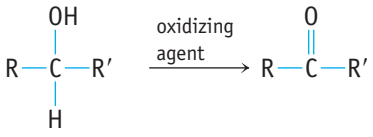


Acids have a sour taste. The word "vinegar" (from the French *vin aigre*) means sour wine. A device to test one's breath for alcohol relies on the oxidation of ethanol (Figure 23.10).

© Cengage Learning/Charles D. Winters

FIGURE 23.10 Alcohol tester. This device for testing a person's breath for the presence of ethanol relies on the oxidation of the alcohol. If present, ethanol is oxidized by potassium dichromate, $K_2Cr_2O_7$, to acetaldehyde and then to acetic acid. The yellow-orange dichromate ion is reduced to green $Cr^{3+}(aq)$, with the color change indicating that ethanol was present.

Oxidation of a *secondary alcohol* produces a ketone:



(—R and —R′ are organic groups. They may be the same or different.)

Common oxidizing agents used for these reactions are reagents such as $KMnO_4$ and $K_2Cr_2O_7$ (◀ Table 3.3).

Finally, tertiary alcohols do *not* react with the usual oxidizing agents.

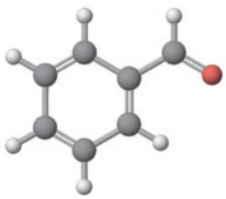
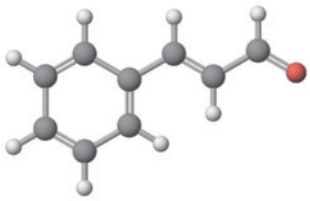
Aldehydes and Ketones

Aldehydes and **ketones** can have pleasant odors and are often used in fragrances. Benzaldehyde is responsible for the odor of almonds and cherries; cinnamaldehyde is found in the bark of the cinnamon tree; and the ketone 4-(*p*-hydroxyphenyl)-2-butanone is responsible for the odor of ripe raspberries (a favorite of the authors of this book). Table 23.8 lists several simple aldehydes and ketones.



benzaldehyde, C_6H_5CHO

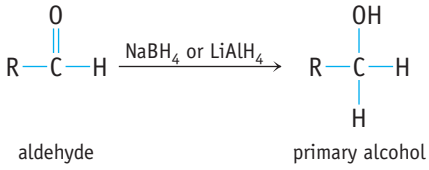


trans-cinnamaldehyde, $C_6H_5CH{=}CHCHO$

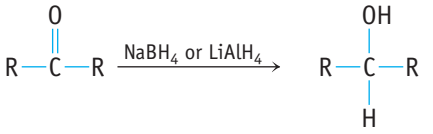
© Cengage Learning/Charles D. Winters

Aldehydes and odors. The odors of almonds and cinnamon are due to aldehydes, whereas the odor of fresh raspberries comes from a ketone.

Aldehydes and ketones are the oxidation products of primary and secondary alcohols, respectively. The reverse reactions—reduction of aldehydes to primary alcohols and reduction of ketones to secondary alcohols—are also known. Commonly used reagents for such reductions are $NaBH_4$ and $LiAlH_4$, although H_2 is used on an industrial scale.



aldehyde primary alcohol



ketone secondary alcohol

Table 23.8 Simple Aldehydes and Ketones

Structure	Common Name	Systematic Name	BP (°C)
$HCH{=}O$	Formaldehyde	Methanal	−19
$CH_3CH{=}O$	Acetaldehyde	Ethanal	20
$CH_3CCH_3{=}O$	Acetone	Propanone	56

PROBLEM SOLVING TIP 23.2
Naming Aldehydes, Ketones, and Carboxylic Acids

Aldehydes: Substitute "-al" for the final "-e" in the name of the hydrocarbon. The carbon atom of an aldehyde is, by definition, carbon-1 in the hydrocarbon chain. For example, the compound $CH_3CH(CH_3)CH_2CH_2CHO$ contains a 5-carbon chain with the aldehyde functional group being carbon-1 and the $-CH_3$ group at position 4; thus, the name is *4-methylpentanal*.

Ketones: Substitute "-one" for the final "-e" in the name of the hydrocarbon. The position of the ketone functional group (the carbonyl group) is indicated by the number of the carbon atom. For example, the compound $CH_3COCH_2CH(C_2H_5)CH_2CH_3$ has the carbonyl group at the 2 position and an ethyl group at the 4 position of a 6-carbon chain; its name is *4-ethyl-2-hexanone*.

Carboxylic acids (organic acids): Substitute "-oic" for the final "-e" in the name of the hydrocarbon. The carbon atoms in the longest chain are counted beginning with the carboxylic carbon atom. For example, *trans*-$CH_3CH{=}CHCH_2CO_2H$ is named as a derivative of *trans*-3-pentene, that is, *trans-3-pentenoic acid*.

Carboxylic Acids

Acetic acid is the most common and most important **carboxylic acid**. For many years, acetic acid was made by oxidizing ethanol produced by fermentation. Now, however, most of the acetic acid is made by combining carbon monoxide and methanol in the presence of a catalyst:

$$\underset{\text{methanol}}{CH_3OH(\ell)} + CO(g) \xrightarrow{\text{catalyst}} \underset{\text{acetic acid}}{CH_3CO_2H(\ell)}$$

About 1 billion kilograms of acetic acid are produced annually in the United States for use in plastics, synthetic fibers, and fungicides.

Many organic acids are found naturally (Table 23.9). Acids are recognizable by their sour taste (Figure 23.11) and are found in common foods: Citric acid in fruits, acetic acid in vinegar, and tartaric acid in grapes are just three examples.

© Cengage Learning/Charles D. Winters

FIGURE 23.11 Acetic acid in bread. Acetic acid is produced in bread leavened with the yeast *Saccharomyces exiguus*. Another group of bacteria, *Lactobacillus sanfrancisco,* contributes to the flavor of sourdough bread. These bacteria metabolize the sugar maltose, excreting acetic acid and lactic acid, $CH_3CH(OH)CO_2H$, thereby giving the bread its unique sour taste.

Table 23.9 Some Naturally Occurring Carboxylic Acids

Name	Structure	Natural Source
Benzoic acid		Berries
Citric acid		Citrus fruits
Lactic acid		Sour milk
Malic acid		Apples
Oleic acid		Vegetable oils
Oxalic acid		Rhubarb, spinach, cabbage, tomatoes
Stearic acid		Animal fats
Tartaric acid		Grape juice, wine

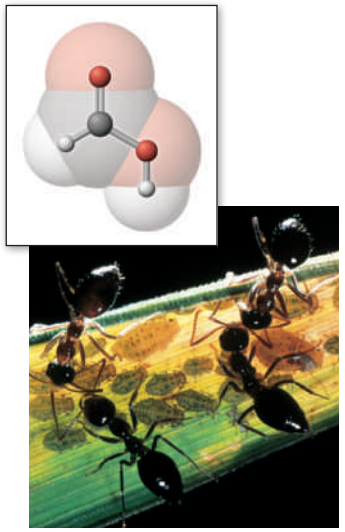
$CH_3(CH_2)_3COH$ (O)	Valeric acid	Pentanoic acid	187



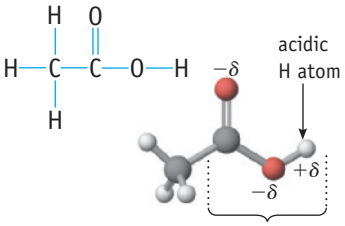
© Cengage Learning/Charles D. Winters

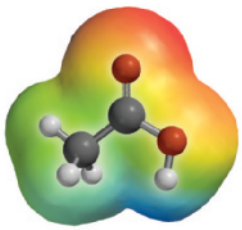
Formic acid, HCO_2H. This acid puts the sting in ant bites.

Some carboxylic acids have common names derived from the source of the acid (Tables 23.9 and 23.10). Because formic acid is found in ants, its name comes from the Latin word for ant (*formica*). Butyric acid gives rancid butter its unpleasant odor, and the name is related to the Latin word for butter (*butyrum*). The systematic names of acids (Table 23.10) are formed by dropping the "-e" on the name of the corresponding alkane and adding "-oic" (and the word "acid").

Because of the substantial electronegativity of oxygen, the two O atoms of the carboxylic acid group are slightly negatively charged, and the H atom of the —OH group is partially positively charged. This charge distribution has several important implications:

- The polar acetic acid molecule dissolves readily in water, which you already know because vinegar is an aqueous solution of acetic acid. (Acids with larger organic groups are less soluble, however.)
- The hydrogen of the —OH group is the acidic hydrogen. As noted in Table 3.1, acetic acid is a weak acid in water, as are most other organic acids.





Acetic acid. The H atom of the carboxylic acid group (—CO_2H) is the acidic proton of this and other carboxylic acids.

Carboxylic acids undergo a number of reactions. Among these is the reduction of the acid (with reagents such as $LiAlH_4$ or $NaBH_4$) first to an aldehyde and then to an alcohol. For example, acetic acid is reduced first to acetaldehyde and then to ethanol.

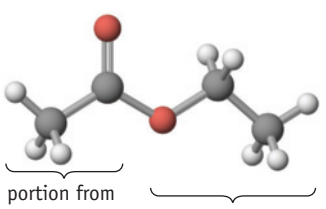
$$\underset{\text{acetic acid}}{CH_3CO_2H} \xrightarrow{LiAlH_4} \underset{\text{acetaldehyde}}{CH_3CHO} \xrightarrow{LiAlH_4} \underset{\text{ethanol}}{CH_3CH_2OH}$$

Yet another important aspect of carboxylic acid chemistry is the reaction with bases to give carboxylate anions. For example, acetic acid reacts with hydroxide ions to give acetate ions and water.

$$CH_3CO_2H(aq) + OH^-(aq) \rightarrow CH_3CO_2^-(aq) + H_2O(\ell)$$

Esters

Esters are the product of the reaction of an acid with an alcohol. Such reactions, called **esterification** reactions, are usually carried out with an acid catalyst (such as HCl). These reactions do not go to completion, however; instead, they proceed to form an equilibrium mixture of the reactants and products. To obtain the ester in good yield, the reaction can be forced to completion. One way to do this is to remove



ethyl acetate, an ester
$CH_3CO_2CH_2CH_3$

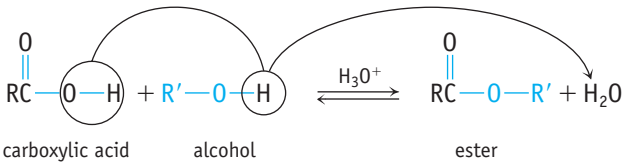
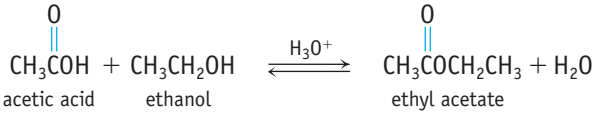
Aspirin, a commonly used analgesic. It is based on benzoic acid with an acetate group, $—O_2CCH_3$, in the *ortho* position. Aspirin has both carboxylic acid and ester functional groups.

water from the system (for example, by distilling it from the reaction mixture); this causes the equilibrium to shift to the right, thus forming more of the ester.

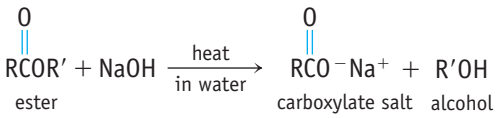


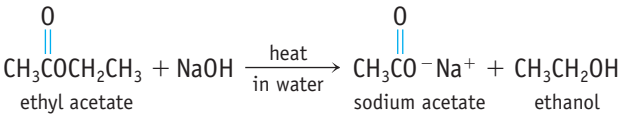


In these reactions the O atom of the alcohol ends up as part of the ester. This is known from isotope labeling experiments. If the reaction is run using an alcohol in which the alcohol oxygen is ^{18}O, all of the ^{18}O ends up in the ester molecule.

Table 23.11 lists a few common esters and the acid and alcohol from which they are formed. The two-part name of an ester is given by (1) the name of the hydrocarbon group from the alcohol and (2) the name of the carboxylate group derived from the acid name by replacing "-ic" with "-ate." For example, ethanol (commonly called ethyl alcohol) and acetic acid combine to give the ester ethyl acetate.

An important reaction of esters is *hydrolysis* (literally, reaction with water), a reaction that is the reverse of the reaction forming the ester. In a neutral solution, this reaction also gives an equilibrium mixture of acid and ester. In order for this reaction to reach completion, however, it is carried out in a basic solution. The base, NaOH for example, reacts with the acid, thus shifting the equilibrium toward the product.





©Cengage Learning/ Charles D. Winters

Esters. Many fruits such as bananas and strawberries as well as consumer products (here, perfume and oil of wintergreen) contain esters.

Table 23.1 1 Some Acids, Alcohols, and Their Esters

Acid	Alcohol	Ester	Odor of Ester
CH_3CO_2H acetic acid	$CH_3CHCH_2CH_2OH$ 3-methyl-1-butanol	$CH_3COCH_2CH_2CHCH_3$ 3-methylbutyl acetate	Banana
$CH_3CH_2CH_2CO_2H$ butanoic acid	$CH_3CH_2CH_2CH_2OH$ 1-butanol	$CH_3CH_2CH_2COCH_2CH_2CH_2CH_3$ butyl butanoate	Pineapple
$CH_3CH_2CH_2CO_2H$ butanoic acid	$C_6H_5CH_2OH$ benzyl alcohol	$CH_3CH_2CH_2COCH_2C_6H_5$ benzyl butanoate	Rose

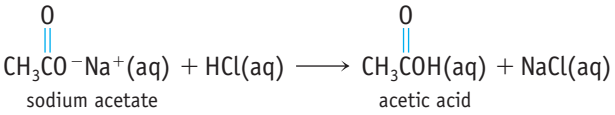
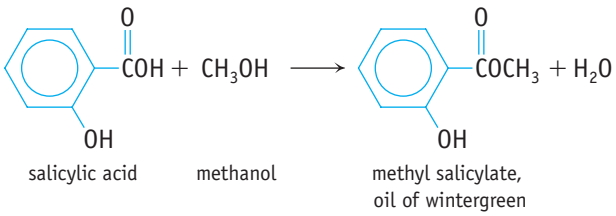
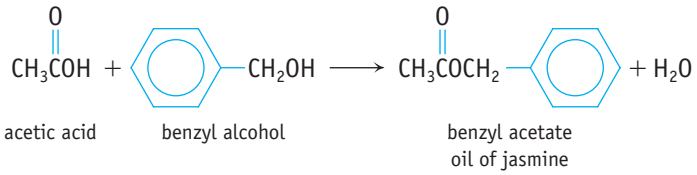
The carboxylic acid can be recovered if the sodium salt is treated with a strong acid such as HCl:



Unlike the acids from which they are derived, esters often have pleasant odors (Table 23.11). Typical examples are methyl salicylate, or "oil of wintergreen," and benzyl acetate. Methyl salicylate is derived from salicylic acid, the parent compound of aspirin.

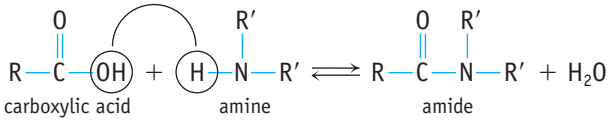


Benzyl acetate, the active component of "oil of jasmine," is formed from benzyl alcohol ($C_6H_5CH_2OH$) and acetic acid. The chemicals are inexpensive, so synthetic jasmine is used as a fragrance in less-expensive perfumes and toiletries.



Amides

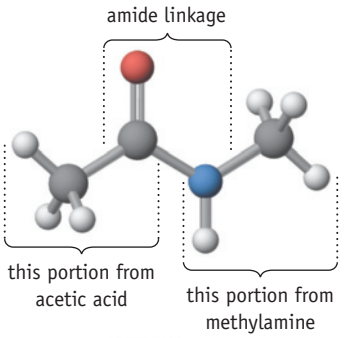
A carboxylic acid and an alcohol react by loss of water to form an ester. In a similar manner, another class of organic compounds—amides—form when a carboxylic acid reacts with an amine, again with loss of water.

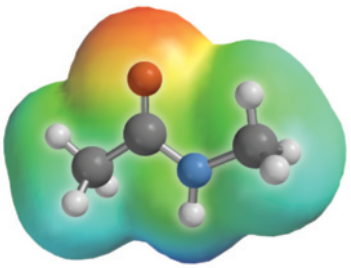


Amides have an organic group and an amino group (—NH_2, —NHR′, or —NR′R) attached to the carbonyl group.

The C atom involved in the amide bond has three bonded groups and no lone pairs around it. We would predict it should be sp^2 hybridized with trigonal-planar geometry and bond angles of approximately 120°—and this is what is found. However, the structure of the amide group offers a surprise. The N atom is also observed to have trigonal-planar geometry with bonds to three attached atoms at 120°. Because the amide nitrogen is surrounded by four pairs of electrons, we would have predicted the N atom would have sp^3 hybridization and bond angles of about 109°.

Based on the observed geometry of the amide N atom, the atom is assigned sp^2 hybridization. To rationalize the observed angle and sp^2 hybridization, we can introduce a second resonance form of the amide.





An amide, *N*-methylacetamide. The *N*-methyl portion of the name derives from the amine portion of the molecule, where the *N* indicates that the methyl group is attached to the nitrogen atom. The "-acet" portion of the name indicates the acid on which the amide is based. The electrostatic potential surface and model show the polarity and planarity of the amide linkage.

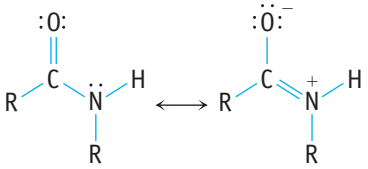
Acetaminophen, *N*-acetyl-*p*-aminophenol. This analgesic is an amide. It is used in over-the-counter painkillers such as Tylenol.



(A) (B)

Form B contains a C═N double bond, and the O and N atoms have negative and positive charges, respectively. The N atom can be assigned sp^2 hybridization, and the π bond in B arises from overlap of p orbitals on C and N.

The second resonance structure for an amide link also explains why the carbon–nitrogen bond is relatively short, about 132 pm, a value between that of a C—N single bond (149 pm) and a C═N double bond (127 pm). In addition, restricted rotation occurs around the C═N bond, making it possible for isomeric species to exist if the two groups bonded to N are different.

The amide grouping is particularly important in some synthetic polymers (▶ Section 23-5) and in proteins, where it is referred to as a *peptide* link. The compound *N*-acetyl-*p*-aminophenol, an analgesic known by the generic name acetaminophen, is another amide. Use of this compound as an analgesic was apparently discovered by accident when a common organic compound called acetanilide (like acetaminophen but without the —OH group) was mistakenly put into a prescription for a patient. Acetanilide acts as an analgesic, but it can be toxic. An —OH group *para* to the amide group makes the compound nontoxic, an interesting example of how a seemingly small structural difference affects chemical function.

EXAMPLE 23.7

Functional Group Chemistry

Problem

(a) Draw the structure of the product of the reaction between propanoic acid and 1-propanol. What is the systematic name of the reaction product, and what functional group does it contain?

(b) What is the result of reacting 2-butanol with an oxidizing agent? Give the name, and draw the structure of the reaction product.

What Do You Know? From the material covered in this chapter, you should know the names, structures, and common chemical reactions of organic compounds mentioned in this question.

Strategy Determine the products of these reactions, based on the discussion in the text. Propanoic acid is a carboxylic acid, and 1-propanol and 2-butanol are both alcohols.

Solution

(a) Carboxylic acids such as propanoic acid react with alcohols to give esters.

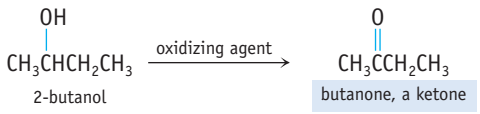
(b) 2-Butanol is a secondary alcohol. Such alcohols are oxidized to ketones.



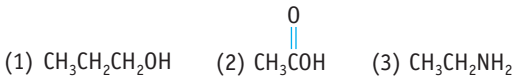
2-butanol

butanone, a ketone

Think about Your Answer Students sometimes find themselves overwhelmed by the large amount of information presented in organic chemistry. Your study of this material will be more successful if you carefully organize information based on the type of compound.

Check Your Understanding

(a) Name each of the following compounds and its functional group.



(b) Name the product from the reaction of compounds 1 and 2 above.

(c) What is the name and structure of the product from the oxidation of 1 with an excess of oxidizing agent?

(d) Give the name and structure of the compound that results from combining 2 and 3.

(e) What is the result of adding an acid (say HCl) to compound 3?

REVIEW & CHECK FOR SECTION 23-4

1. How many aldehydes and ketones are possible that have the formula $C_5H_{10}O$ and that have a five-carbon chain?

   (a) 2 aldehydes and 1 ketone

   (b) 1 aldehyde and 3 ketones

   (c) 1 aldehyde and 1 ketone

   (d) 1 aldehyde and 2 ketones

A CLOSER LOOK Omega-3-Fatty Acids

There is considerable interest today in incorporating omega-3-fatty acids in the diet. Although potential health benefits are not fully defined, proponents say there is some evidence that they lower blood pressure and reduce the chances of heart attacks and strokes. Sources of omega-3-fatty acids include fish and plant oils.

These compounds are polyunsaturated, long-chain carboxylic acids, and there are a number of different, naturally occurring compounds in this class.

The word "omega" in the name refers to the last carbon atom in the carbon chain of the acid, and the number 3 indicates that there is a double bond between carbon atoms 3 and 4 when counted from that end of the molecule.

An example of an omega-3-fatty acid is all-*cis*-7,10,13-hexadecatrienoic acid, whose structure is shown here. Naming large complicated molecules is challenging, but it is possible to decipher the structure from the name. *Hexadeca* identifies this as a 16-carbon atom compound, *triene* tells us there are 3 double bonds (all with *cis* geometry), and the *oic* ending defines it as a carboxylic acid. The numbers 7, 10, and 13 indicate the positions of the double bonds relative to the carboxylic carbon atom.

2. Addition of water to 2-butene gives a single product. Oxidation of this product with $K_2Cr_2O_7$ gives a single compound. What is its name?

   (a) butanal (c) 2-butanol

   (b) 2-butanone (d) butane

3. What is the bond angle of the O—C—O group of atoms in benzoic acid and what is the hybridization of the carbonyl carbon atom?

   (a) 90°, not hybridized (c) 180°, *sp* hybridized

   (b) 109.5°, sp^3 hybridized (d) 120°, sp^2 hybridized

4. A sample of ethanol is divided into two portions. One portion is oxidized with excess oxidizing agent to give an acid. The acid and the remaining alcohol react to give an ester. What is the name of the ester?

   (a) ethyl propanoate (c) ethyl ethanoate

   (b) ethanoic acid (d) methyl propanoate

23-5 Polymers

We turn now to the very large molecules known as *polymers*. These can be either synthetic materials or naturally occurring substances such as proteins or nucleic acids. Although many different types of polymers are known and they have widely different compositions and structures, their properties are understandable, based on the principles developed for small molecules.

Classifying Polymers

The word *polymer* means "many parts" (from the Greek, *poly* and *meros*). Thus, **polymers** are giant molecules made by chemically joining many small molecules called **monomers**. Polymer molar masses can range from thousands to millions.

Extensive use of synthetic polymers is a fairly recent development. A few synthetic polymers (Bakelite, rayon, and celluloid) were made early in the 20th century, but most of the products with which you are likely to be familiar originated in the last 75 years. By 1976, synthetic polymers outstripped steel as the most widely used materials in the United States. The average production of synthetic polymers in the United States is now 150 kg or more per person annually.

The polymer industry classifies polymers in several different ways. One is their response to heating. **Thermoplastics** (such as polyethylene) soften and flow when they are heated and harden when they are cooled. **Thermosetting plastics** (such as Formica) are initially soft but set to a solid when heated and cannot be resoftened. Another classification scheme depends on the end use of the polymer—for example, plastics, fibers, elastomers, coatings, and adhesives.

A more chemically oriented approach to polymer classification is based on the method of synthesis. **Addition polymers** are made by directly adding monomer units together. **Condensation polymers** are made by combining monomer units and splitting out a small molecule, often water.

Addition Polymers

Polyethylene, polystyrene, and polyvinyl chloride (PVC) are common addition polymers (Figure 23.12). They are built by "adding together" simple alkenes such as ethylene ($CH_2{=}CH_2$), styrene ($C_6H_5CH{=}CH_2$), and vinyl chloride ($CH_2{=}CHCl$). These and other addition polymers (Table 23.12), all derived from alkenes, have widely varying properties and uses.

FIGURE 23.12 Common polymer-based consumer products. Recycling information is provided on most plastics (often molded into the bottom of bottles). High-density polyethylene is designated with a "2" inside a triangular symbol and the letters "HDPE." Polystyrene is designated by "6" with the symbol PS, and polyvinyl chloride, PVC, is designated with a "3" inside a triangular symbol with the symbol "V" or "PVC" below.

Table 23.12 Ethylene Derivatives That Undergo Addition

Formula	Monomer Common Name	Polymer Name (Trade Names)	Uses
	Ethylene	Polyethylene (polythene)	Squeeze bottles, bags, films, toys and molded objects, electric insulation
	Propylene	Polypropylene (Vectra, Herculon)	Bottles, films, indoor-outdoor carpets
	Vinyl chloride	Polyvinyl chloride (PVC)	Floor tile, raincoats, pipe
	Acrylonitrile	Polyacrylonitrile (Orlon, Acrilan)	Rugs, fabrics
	Styrene	Polystyrene (Styrofoam, Styron)	Food and drink coolers, building material, insulation
	Vinyl acetate	Polyvinyl acetate (PVA)	Latex paint, adhesives, textile coatings
	Methyl methacrylate	Polymethyl methacrylate (Plexiglas, Lucite)	High-quality transparent objects, latex paints, contact lenses
	Tetrafluoroethylene	Polytetrafluoroethylene (Teflon)	Gaskets, insulation, bearings, pan coatings

Polyethylene film. The polymer film is produced by extruding the molten plastic through a ring-like gap and inflating the film like a balloon.

Polyethylene and Other Polyolefins

Polyethylene is by far the leader in amount of polymer produced. Ethylene (C_2H_4), the monomer from which polyethylene is made, is a product of petroleum refining and one of the top five chemicals produced in the United States. When ethylene is heated to between 100 and 250 °C at a pressure of 1000 to 3000 atm in the presence of a catalyst, polymers with molar masses up to several million are formed. The reaction can be expressed as the chemical equation:

$$n\ H_2C{=}CH_2 \longrightarrow \left(\begin{array}{cc} H & H \\ | & | \\ C & C \\ | & | \\ H & H \end{array}\right)_n$$

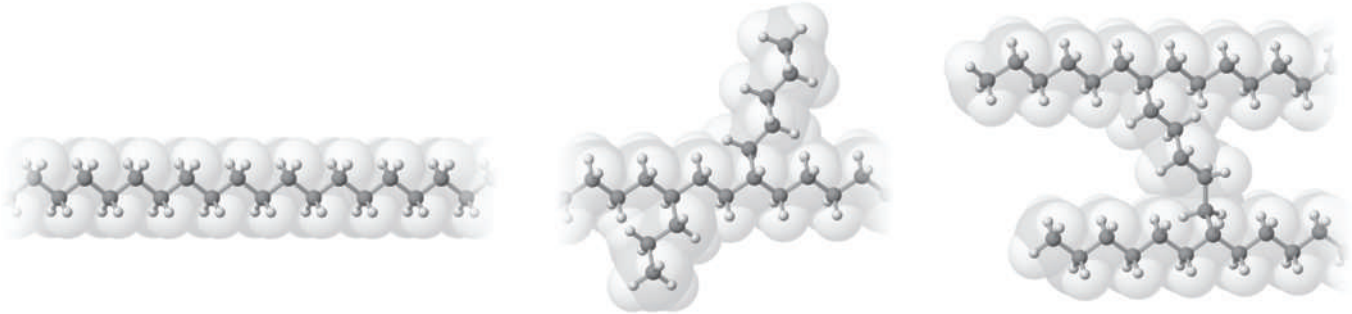
ethylene polyethylene

The abbreviated formula of the reaction product, $\text{—}CH_2CH_2\text{—}_n$, shows that polyethylene is a chain of carbon atoms, each bearing two hydrogens. The chain length for polyethylene can be very long. A polymer with a molar mass of 1 million would contain almost 36,000 ethylene molecules linked together.

Samples of polyethylene formed under various pressures and catalytic conditions have different properties, as a result of different molecular structures. For example, when chromium(III) oxide is used as a catalyst, the product is almost exclusively a linear chain (Figure 23.13a). If ethylene is heated to 230 °C at high pressure, however, irregular branching occurs (Figure 23.13b). Still other conditions lead to cross-linked polyethylene, in which different chains are linked together (Figure 23.13c).

The high molar mass chains of linear polyethylene pack closely together and result in a material with a density of 0.97 g/cm^3. This material, referred to as high-density polyethylene (HDPE), is hard and tough, which makes it suitable for items such as milk bottles. If the polyethylene chain contains branches, however, the chains cannot pack as closely, and a lower-density material (0.92 g/cm^3) known as low-density polyethylene (LDPE) results. This material is softer and more flexible than HDPE. It is used in plastic wrap and sandwich bags, among other things. Linking up the polymer chains in cross-linked polyethylene (CLPE) causes the material to be even more rigid and inflexible. Plastic bottle caps are often made of CLPE.

Polymers formed from substituted ethylenes ($CH_2{=}CHX$) have a range of properties and uses (see Table 23.12). Sometimes, the properties are predictable based on the molecule's structure. Polymers without polar substituent groups, such



(a) The linear form, high-density polyethylene (HDPE).

(b) Branched chains occur in low-density polyethylene (LDPE).

(c) Cross-linked polyethylene (CLPE).

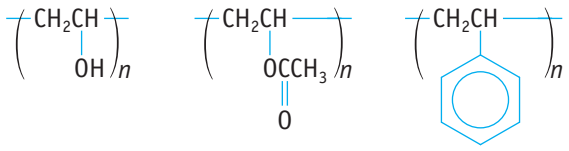
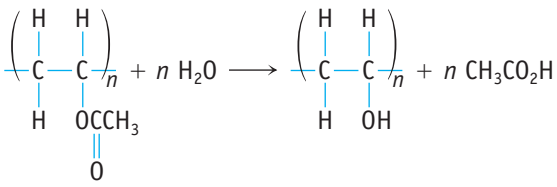
as polystyrene, often dissolve in organic solvents, a property useful for some types of fabrication.

polymers based on substituted ethylenes, $H_2C{=}CHX$



polyvinyl alcohol polyvinyl acetate polystyrene

Polyvinyl alcohol is a polymer with little affinity for nonpolar solvents but an affinity for water, which is not surprising, based on the large number of polar OH groups (Figure 23.14). Vinyl alcohol ($CH_2{=}CHOH$) is not a stable compound (it isomerizes to acetaldehyde CH_3CHO), so polyvinyl alcohol cannot be made from this compound. Instead, it is made by hydrolyzing the ester groups in polyvinyl acetate.



Solubility in water or organic solvents can be a liability for polymers. The many uses of polytetrafluoroethylene [Teflon, $\text{—}(CF_2CF_2)_n\text{—}$] stem from the fact that it does not interact with water or organic solvents.

Polystyrene, with $n = 5700$, is a clear, hard, colorless solid that can be molded easily at 250 °C. However, you are probably more familiar with the very light, foamlike material known as Styrofoam that is used widely for food and beverage containers and for home insulation (see Figure 23.12). Styrofoam is produced by a process called "expansion molding." Polystyrene beads containing 4% to 7% of a low-boiling liquid like pentane are placed in a mold and heated with steam or hot air. Heat causes the solvent to vaporize, creating a foam in the molten polymer that expands to fill the shape of the mold.

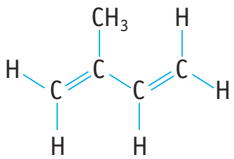
FIGURE 23.14 Slime from polyvinyl alcohol. When boric acid, $B(OH)_3$, is added to an aqueous suspension of polyvinyl alcohol, $(CH_2CHOH)_n$, the mixture becomes very viscous because boric acid reacts with the —OH groups on the polymer chain, causing cross-linking to occur. (The model shows an idealized structure of a portion of the polymer.)

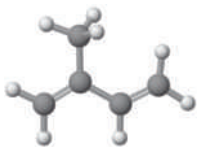
Natural and Synthetic Rubber

Natural rubber was first introduced in Europe in 1740, but it remained a curiosity until 1823, when Charles Macintosh invented a way of using it to waterproof cotton cloth. The macintosh, as rain coats are still sometimes called, became popular despite major problems: Natural rubber is notably weak and is soft and tacky when warm, but it is brittle at low temperatures. In 1839, after 5 years of research on natural rubber, the American inventor Charles Goodyear (1800–1860) discovered that heating gum rubber with sulfur produces a material that is elastic, water-repellent, resilient, and no longer sticky.

Rubber is a naturally occurring polymer, the monomers of which are molecules of 2-methyl-1,3-butadiene, commonly called *isoprene*. In natural rubber, isoprene monomers are linked together through carbon atoms 1 and 4—that is, through the end carbon atoms of the C_4 chain (Figure 23.15). This leaves a double bond between carbon atoms 2 and 3. In natural rubber, these double bonds have a *cis* configuration.

In vulcanized rubber, the material that Goodyear discovered, the polymer chains of natural rubber are cross-linked by short chains of sulfur atoms. Cross-linking helps to align the polymer chains, so the material does not undergo a permanent change when stretched and it springs back when the stress is removed. Substances that behave this way are called **elastomers**.





isoprene, 2-methyl-1,3-butadiene

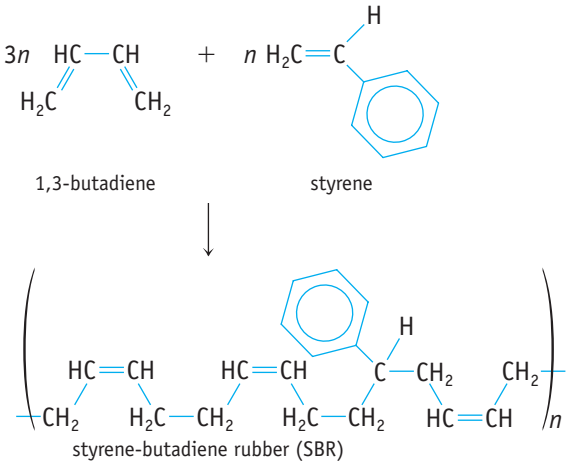
FIGURE 23.15 Natural rubber. The sap that comes from the rubber tree is a natural polymer of isoprene. All the linkages in the carbon chain are *cis*. When natural rubber is heated strongly in the absence of air, it smells of isoprene. This observation provided a clue that rubber is composed of this building block.

With a knowledge of the composition and structure of natural rubber, chemists began searching for ways to make synthetic rubber. When they first tried to make the polymer by linking isoprene monomers together, however, what they made was sticky and useless. The problem was that synthesis procedures gave a mixture of *cis*- and *trans*-polyisoprene. In 1955, however, chemists at the Goodyear and Firestone companies discovered special catalysts to prepare the all-*cis* polymer. This synthetic material, which was structurally identical to natural rubber, is now manufactured cheaply. In fact, more than 8.0×10^8 kg of synthetic polyisoprene is produced annually in the United States. Other kinds of polymers have further expanded the repertoire of elastomeric materials now available. Polybutadiene, for example, is currently used in the production of tires, hoses, and belts.

Some elastomers, called **copolymers**, are formed by polymerization of two (or more) different monomers. A copolymer of butadiene and styrene, made with a 3:1 ratio of these raw materials, is the most important synthetic rubber now made; more than 1 billion kilograms of styrene-butadiene rubber (SBR) is produced each year in the United States for making tires. And a little is left over each year to make bubble gum. The stretchiness of bubble gum once came from natural rubber, but SBR is now used to help you blow bubbles.



A CLOSER LOOK Copolymers and Engineering Plastics for Lego Bricks and Tattoos

Many commonly used products are not made of a single monomer but are copolymers or a combination of polymers. One example is ABS plastic. This is a copolymer of acrylonitrile (A) and styrene (S), which is made in the presence of polybutadiene (B).

The result is a thermoplastic that holds color well and has a shiny, impervious surface. It is used to make many consumer items: toys (such as Lego bricks), automobile body parts, and pressure tubing for water and other fluids. There is evidence that some tattoo inks with vivid colors also contain ABS plastic.

When acrylonitrile and styrene are polymerized in the presence of polybutadiene, short chains of the acrylonitrile-styrene polymer are mingled with longer polybutadiene chains. The polar —CN groups from neighboring ABS chains interact with each other and bind the chains together. The result is a stronger plastic than polystyrene.

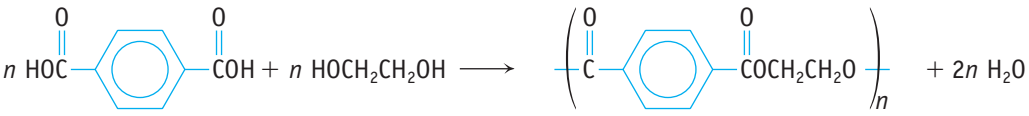
Condensation Polymers

A chemical reaction in which two molecules react by splitting out, or eliminating, a small molecule is called a **condensation reaction**. The reaction of an alcohol with a carboxylic acid to give an ester is an example of a condensation reaction. One way to form a condensation polymer uses *two* different reactant molecules, each containing *two* functional groups. Another route uses a single molecule with two different functional groups. Commercial polyesters are made using both types of reactions.

Polyesters

Terephthalic acid contains two carboxylic acid groups, and ethylene glycol contains two alcohol groups. When mixed, the acid and alcohol functional groups at both ends of these molecules can react to form ester linkages, splitting out water. The result is a condensation polymer called polyethylene terephthalate (PET). The multiple ester linkages make this substance a **polyester** (Figure 23.16).



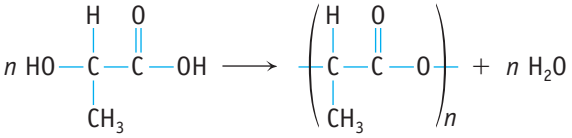
terephthalic acid ethylene glycol polyethylene terephthalate (PET), a polyester

PET is also made by a reaction between methyl terephthalate and ethylene glycol, a reaction called **transesterification**. In this reaction one ester is converted to another, and removal of methanol by distillation allows the reaction to reach completion.

$$n\ CH_3O_2CC_6H_4CO_2CH_3 + n\ HOCH_2CH_2OH \rightleftharpoons —(O_2CC_6H_4CO_2CH_2CH_2)_n— + 2n\ CH_3OH$$

Polyester textile fibers made from PET are marketed as Dacron and Terylene. The inert, nontoxic, nonflammable, and non-blood-clotting properties of Dacron polymers make Dacron tubing an excellent substitute for human blood vessels in heart bypass operations, and Dacron sheets are sometimes used as temporary skin for burn victims. A polyester film, Mylar, has unusual strength and can be rolled into sheets one-thirtieth the thickness of a human hair.

There is considerable interest in another polyester, polylactic acid (PLA). Lactic acid contains both carboxylic acid and alcohol functional groups, so condensation between molecules of this monomer gives a polymer.



The interest in polylactic acid arises because it is "green" for several reasons. First, the monomer used to make this polymer is obtained by biological fermentation of plant materials. As a result, formation of this polymer is carbon-neutral. All of the carbon in this polymer came from CO_2 in the atmosphere, and degradation at some future time will return the same quantity of CO_2 to the environment. In addition, this polymer, which is currently being used in packaging material, is biodegradable, which has the potential to alleviate landfill disposal problems.

Polyamides

In 1928, the DuPont Company embarked on a basic research program headed by Wallace Carothers (1896–1937). Carothers was interested in high molar mass compounds, such as rubbers, proteins, and resins. In 1935, his research yielded nylon-6,6

A CLOSER LOOK Green Chemistry: Recycling PET

In 2009, the world production of polyethylene terephthalate amounted to 49.2 billion kg. Most of this was used to produce fibers and packaging materials; the remainder was used for automobile parts, luggage, filters, and much more. Currently, much of the PET used to make beverage containers is recycled.

The recycling process uses some familiar chemistry. Scrap PET is dissolved at over 220 °C in dimethyl phthalate (DMT) and then treated with methanol at 260–300 °C and 340–650 kPa. In this process, the methanol reacts with the polymer to break down the chains forming more DMT and ethylene glycol. DMT and ethylene glycol are separated, purified, and used to make more PET.

The recovery of DMT and ethylene glycol means that increasingly scarce petroleum is not needed to make the starting materials for the manufacture of billions of kilograms of new PET!

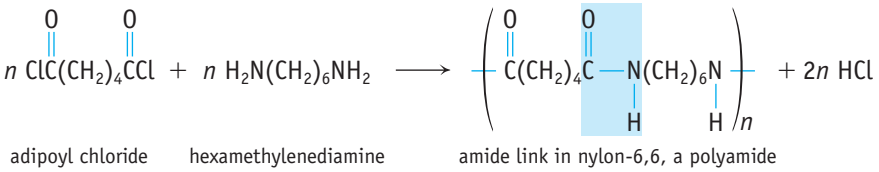
FIGURE 23.17 Nylon-6,6. Hexamethylenediamine is dissolved in water *(bottom layer),* and adipoyl chloride (a derivative of adipic acid) is dissolved in hexane *(top layer).* The two compounds react at the interface between the layers to form nylon-6,6, which is being wound onto a stirring rod.

(Figure 23.17), a **polyamide** prepared from adipoyl chloride, a derivative of adipic acid (a diacid) and hexamethylenediamine (a diamine):



Nylon can be extruded easily into fibers that are stronger than natural fibers and chemically more inert, and this fact jolted the American textile industry at a critical time. Natural fibers were not meeting 20th-century needs. Silk was expensive and not durable, wool was scratchy, linen crushed easily, and cotton did not have a high-fashion image. Perhaps the most identifiable use for the new fiber was in nylon stockings. The first public sale of nylon hosiery took place on October 24, 1939, in Wilmington, Delaware (the site of DuPont's main office). This use of nylon in commercial products ended shortly thereafter, however, with the start of World War II. All nylon was diverted to making parachutes and other military gear. It was not until about 1952 that nylon reappeared in the consumer marketplace.

Figure 23.18 illustrates why nylon makes such a good fiber. To have good tensile strength (the ability to resist tearing), the polymer chains should be able to attract one another, albeit not so strongly that the plastic cannot be drawn into fibers. Ordinary covalent bonds between the chains (cross-linking) would be too strong. Instead, cross-linking occurs by the somewhat weaker intermolecular force called *hydrogen bonding* (◀ Section 11-3) between the hydrogens of N—H groups on one chain and the carbonyl oxygens on another chain. The polarities of the $N^{\delta-}$—$H^{\delta+}$ group and the $C^{\delta+}$=$O^{\delta-}$ group lead to attractive forces between the polymer chains of the desired magnitude.

EXAMPLE 23.8

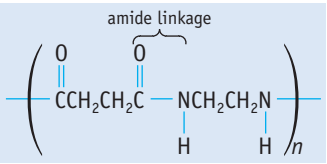
Condensation Polymers

Problem What is the repeating unit of the condensation polymer obtained by combining $HO_2CCH_2CH_2CO_2H$ (succinic acid) and $H_2NCH_2CH_2NH_2$ (1,2-ethylenediamine)?

What Do You Know? Carboxylic acids and amines react to form amides, splitting out water. Here we have a diacid and diamine that will react. The repeating unit will be the shortest sequence that when repeated gives a long polymer chain.

Strategy Recognize that the polymer will link the two monomer units through the amide linkage. The smallest repeating unit of the chain will contain two parts, one from the diacid and the other from the diamine.

Solution The repeating unit of this polyamide is



Think about Your Answer Alternating fragments of the diacid and diamine appear in the polymer chain. The fragments are linked by amide bonds making this a polyamide.

Check Your Understanding

Kevlar is a well-known polymer that is now used to make sports equipment and bullet-proof vests. The basic structure of the polymer is shown below. Is this a condensation polymer or an addition polymer? What chemicals could be used to make this polymer? Write a balanced equation for the formation of Kevlar.

CASE STUDY Green Adhesives

Chemist Kaichang Li was trained in the chemistry of wood and is now doing research at Oregon State University. Oregon has a beautiful and rugged coast, and Li went there in search of mussels to make a special dish. As the waves pounded onshore, he was struck by the fact that the mussels could cling stubbornly to the rocks in spite of the force of the waves and tides. What glue enabled them to do this?

Back in his lab Li found that the strands of glue were largely protein-based. Proteins are simply polymers of amino acids with an amide link between units (see Chapter 24). Li realized that such polymers could have enormous application in the wood industry.

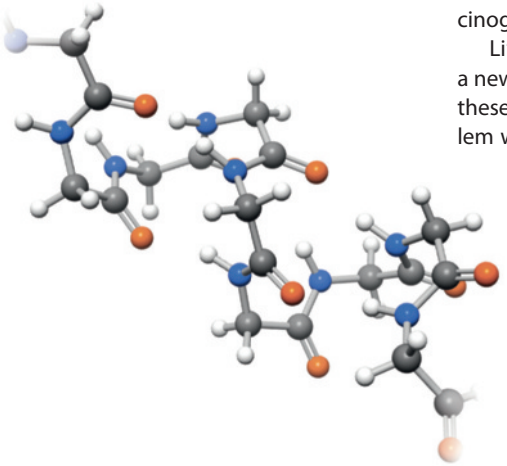

FIGURE A A portion of a protein chain made of repeating glycine molecules ($H_2NCH_2CO_2H$).

Adhesives, or glues in common terminology, have been known and used for thousands of years. Early glues were based on animal or plant products. Now, however, adhesives are largely synthetic, among them are condensation polymers based on the combination of phenol or urea with formaldehyde. These have been used for well over a half-century in the manufacture of plywood and particle board, and your home or dormitory likely contains a significant amount of these building materials. Unfortunately, they have a disadvantage. In their manufacture and use, formaldehyde, a suspected carcinogen, can be released into the air.

Li's work with mussels eventually led to a new, safer adhesive that could be used in these same wood products. His first problem was how to make a protein-based adhesive in the laboratory. The idea came to him one day at lunch when he was eating tofu, a soy-based food very high in protein. Why not modify soy protein to make a new adhesive? Using mussels as his model, Li did exactly that, and, as he said, "We turned soy proteins into mussel adhesive proteins."

Scientists at Hercules Chemical Company provided expertise to cure (or harden) the new "green" adhesive, and the Columbia Forest Products Company adopted the environmentally friendly adhesive for use in plywood and particle board.

Courtesy of Oregon State University

Professor K. Li, a discoverer of "green" adhesives.

In 2007 Li and his coworkers, as well as Columbia Forest Products and Hercules, shared a Presidential Green Chemistry Challenge Award.

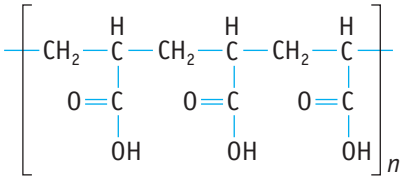
Questions:

1. Draw structures of phenol, urea, and formaldehyde.
2. Describe the bonding in formaldehyde.
3. It has been said that nylon is similar to a protein. Compare and contrast the structures of nylon-6,6 and a protein (for more information on the structure of proteins, see Chapter 24).

Answers to these questions are available in Appendix N.

REVIEW & CHECK FOR SECTION 23-5

1. Polyacrylic acid, shown below, is made from which of the following monomers? (The sodium salt of this polymer, sodium polyacrylate, and cellulose are the important ingredients in disposable baby diapers.)



(a) $CH_2=CH_2$ **(b)** $CH_2=CH(CN)$ **(c)** $CH_2=CH(CO_2H)$ **(d)** $CH_2=CH(OH)$

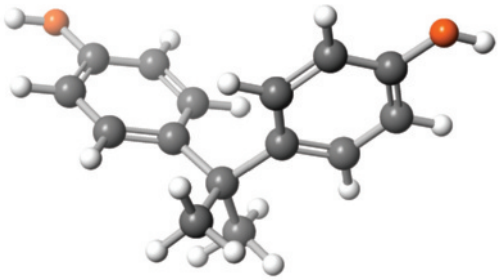
APPLYING CHEMICAL PRINCIPLES

Bisphenol A (BPA)

Bisphenol A (BPA) is an organic compound consisting of two phenol groups linked through a carbon atom. It was first synthesized around 1900 but only recently has it become commercially important. And even more recently it has been very much in the news because of its much-debated possible toxicity.

Bisphenol A is a white solid, slightly water soluble (300 mg/L), and a weak acid (pK_a of 9.9). In 2011 the total world demand for BPA was about 5.4×10^9 kg.



bisphenol-A

If BPA is treated with phosgene (Cl_2CO), the product is the polymer polycarbonate, and approximately 74% of the BPA is used to make this polymer. Because polycarbonate is lightweight, durable, clear, and nearly shatterproof, it is used to make, among other things, bottles, eyeglass lenses, football helmets, and CDs and DVDs.

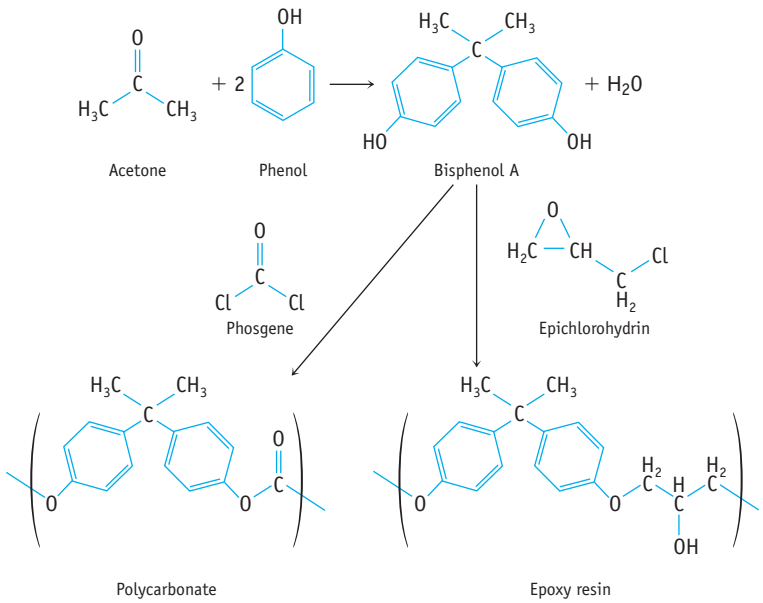
Another 20% of BPA is converted into epoxy resins by reacting BPA with epichlorohydrin. Until recently epoxy resins were used to coat the inside of some food cans, but they still find use in paints and coatings, adhesives, and composite materials.

Some of the remaining 6% of BPA is used in thermal paper. When you get a cash register receipt in a restaurant or store, the coating on the paper may contain BPA.

BPA is such a useful material. What could go wrong? The problem is that BPA has estrogenic activity, the ability to simulate the activity of primary female sex hormones. But this is also true for some compounds found naturally in beans, olive oil, and some fruits and vegetables. Nonetheless, there has been a vigorous debate on the biological effects of BPA and its polymers.

Because of this debate the use of BPA polymers has been virtually eliminated in making bottles (especially baby bottles) and for coating food cans. Substitutes are also being found for BPA in cash register receipts.

The Environmental Protection Agency (EPA) currently states that it is safe to ingest up to 50 μg per kilogram of body weight per day. However, many scientists believe the safe limit should be much lower, or that BPA should be eliminated entirely. To put this in context, some studies have indicated that infants fed from polycarbonate bottles may ingest up to 13 μg/kg/day. A normal adult may take in about 1.5 μg/kg/day.



Synthesis of BPA and polycarbonate and epoxy resin from BPA

Most drinking bottles are no longer made of BPA-based polymers.

In a series of articles on BPA and its effects in *Chemical & Engineering News*, the authors wrote, "Given mounting knowledge of BPA's estrogen-mimicking properties and possible toxic effects, decisions have to be made on whether it should continue to be freely used, restricted for some uses, or banned completely. There are no simple answers."

QUESTIONS:

1. What is the atom economy for the reaction of acetone with phenol to make BPA? (See page 150; *Case Study: Green Chemistry and Atom Economy.*)
2. Are polycarbonate and epoxy resins addition polymers or condensation polymers?
3. Does an infant, who weighs about 15 lb, ingest over 50 μg per day? (1.00 lb = 454 g)
4. Assume you weigh 156 lb. How much BPA do you ingest per day?
5. What quantity of 0.050 M NaOH would be required to react with 300 mg of BPA in 1.00 L of water? (Assume both —OH groups react with NaOH.)

Chemical & Engineering News, June 6, 2011, pages 13–22.

CHAPTER GOALS REVISITED

Now that you have studied this chapter, you should ask whether you have met the chapter goals. In particular, you should be able to:

UNDERSTAND

- General principles of structure and bonding applied to organic compounds.
- Why carbon forms a vast array of diverse chemical compounds.

DO

- Classify organic compounds based on formula and structure.
- Recognize and draw structures of structural isomers and stereoisomers for carbon compounds.
  - **a.** Recognize and draw structures of geometric isomers and optical isomers (Section 23-1). Study Questions: 11, 12, 15, 19, 69.
- Draw structures of molecules, given the name and/or the formula, and name organic compounds using standard nomenclature rules.
  - **a.** Draw structural formulas, and name simple hydrocarbons, including alkanes, alkenes, alkynes, and aromatic compounds (Section 23-2). Study Questions: 1–16, 69, 70, 77.
  - **b.** Identify possible isomers for a given formula (Section 23-2). Study Questions: 6, 8, 11, 15, 16, 19–22, 28.
  - **c.** Name and draw structures of alcohols and amines (Section 23-3). Study Questions: 37–42.
  - **d.** Name and draw structures of carbonyl compounds—aldehydes, ketones, acids, esters, and amides (Section 23-4). Study Questions: 47–50.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Predict the products of common organic reactions.
  - **a.** Predict the products of the reactions of alkenes, aromatic compounds, alcohols, amines, aldehydes and ketones, and carboxylic acids. Study Questions: 23–26, 29, 30, 33–36, 43–46, 51–56, 59, 62, 71–74, 89, 91, 95.
- Identify common polymers.
  - **a.** Write equations for the formation of addition polymers and condensation polymers, and describe their structures (Section 23-5). Study Questions: 63–66.
  - **b.** Relate properties of polymers to their structures (Section 23-5). Study Question: 109.
- Relate properties to molecular structure.
  - **a.** Describe the physical and chemical properties of the various classes of hydrocarbon compounds (Section 23-2). Study Question: 17.
  - **b.** Recognize the connection between the structures and the properties of alcohols (Section 23-3). Study Questions: 45, 46, 72.
  - **c.** Know the structures and properties of some natural products (Section 23-4). Study Questions: 57, 58, 83, 84, 87.

REMEMBER

- Common chemical and physical properties of organic compounds.
- Names, structures, and properties of common organic polymers.

▲ denotes challenging questions.

Blue-numbered questions have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Alkanes and Cycloalkanes

(See Section 23-2 and Examples 23.1 and 23.2.)

1. What is the name of the straight (unbranched) chain alkane with the formula C_7H_{16}?

2. What is the molecular formula for an alkane with 12 carbon atoms?

3. Which of the following compounds can be an alkane?

(a) C_2H_4 (c) $C_{14}H_{30}$
(b) C_5H_{12} (d) C_7H_8

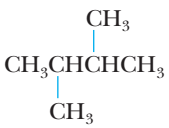
4. Which of the following compounds can be a cyclo-alkane?

(a) C_3H_5 (c) $C_{14}H_{30}$
(b) C_5H_{10} (d) C_8H_8

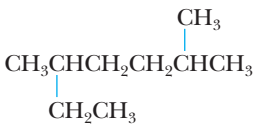
5. One of the structural isomers with the formula C_9H_{20} has the name 3-ethyl-2-methylhexane. Draw its structure. Draw and name another structural isomer of C_9H_{20} in which there is a five-carbon chain.

6. Isooctane, 2,2,4-trimethylpentane, is one of the possible structural isomers with the formula C_8H_{18}. Draw the structure of this isomer, and draw and name structures of two other isomers of C_8H_{18} in which the longest carbon chain is five atoms.

7. Give the systematic name for the following alkane:



8. Give the systematic name for the following alkane. Draw a structural isomer of the compound, and give its name.



9. Draw the structure of each of the following compounds:

(a) 2,3-dimethylhexane
(b) 2,3-dimethyloctane
(c) 3-ethylheptane
(d) 3-ethyl-2-methylhexane

10. Draw structures for the following compounds.

(a) 3-ethylpentane (c) 2,4-dimethylpentane
(b) 2,3-dimethylpentane (d) 2,2-dimethylpentane

11. Draw Lewis structures and name all possible alkanes that have a seven-carbon chain with one methyl substituent group. Which of these isomers has a chiral carbon center?

12. Four (of six possible) dimethylhexanes are named below. Draw the structures of each, and determine which of these isomers has a chiral carbon center.

(a) 2,2-dimethylhexane (c) 2,4-dimethylhexane
(b) 2,3-dimethylhexane (d) 2,5-dimethylhexane

13. Draw the structure of the chair form of cyclohexane. Identify the axial and equatorial hydrogen atoms in this drawing.

14. Draw a structure for cycloheptane. Is the seven-member ring planar? Explain your answer.

15. There are two ethylheptanes (compounds with a seven-carbon chain and one ethyl substituent). Draw the structures, and name these compounds. Is either isomer chiral?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

16. Among the 18 structural isomers with the formula C_8H_{18} are two with a five-carbon chain having one ethyl and one methyl substituent group. Draw their structures, and name these two isomers.

17. List several typical physical properties of C_4H_{10}. Predict the following physical properties of dodecane, $C_{12}H_{26}$: color, state (s, ℓ, g), solubility in water, solubility in a nonpolar solvent.

18. Write balanced equations for the following reactions of alkanes.

(a) The reaction of methane with excess chlorine.
(b) Complete combustion of cyclohexane, C_6H_{12}, with excess oxygen.

Alkenes and Alkynes

(See Section 23-2 and Examples 23.3 and 23.4.)

19. Draw structures for the *cis* and *trans* isomers of 4-methyl-2-hexene.

20. What structural requirement is necessary for an alkene to have *cis* and *trans* isomers? Can *cis* and *trans* isomers exist for an alkane? For an alkyne?

21. A hydrocarbon with the formula C_5H_{10} can be either an alkene or a cycloalkane.

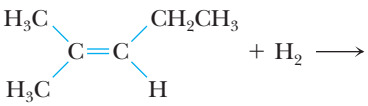
(a) Draw a structure for each of the six isomers possible for C_5H_{10}, assuming it is an alkene. Give the systematic name of each isomer.
(b) Draw a structure for a cycloalkane having the formula C_5H_{10}.

22. Five alkenes have the formula C_7H_{14} and a seven-carbon chain. Draw their structures and name them.

23. Draw the structure and give the systematic name for the products of the following reactions:

(a) $CH_3CH{=}CH_2 + Br_2 \rightarrow$
(b) $CH_3CH_2CH{=}CHCH_3 + H_2 \rightarrow$

24. Draw the structure and give the systematic name for the products of the following reactions:



(a) H_3C, CH_2CH_3, $C{=}C$, H_3C, H, $+ H_2 \longrightarrow$

(b) $CH_3C{\equiv}CCH_2CH_3 + 2\ Br_2 \longrightarrow$

25. The compound 2-bromobutane is a product of addition of HBr to three different alkenes. Identify the alkenes and write an equation for the reaction of HBr with one of the alkenes.

26. The compound 2,3-dibromo-2-methylhexane is formed by addition of Br_2 to an alkene. Identify the alkene, and write an equation for this reaction.

27. Draw structures for the four alkenes that have the formula C_3H_5Cl, and name each compound. (These are derivatives of propene in which a chlorine atom replaces one hydrogen atom.)

28. There are seven possible dichloropropene isomers (molecular formula $C_3H_4Cl_2$). Draw their structures and name each isomer. (Hint: Don't overlook *cis-trans* isomers.)

29. Hydrogenation is an important chemical reaction of compounds that contain double bonds. Write a chemical equation for the hydrogenation of 1-hexene. Hydrogenation reactions are used extensively in the food industry. Describe this reaction and explain its use and importance.

30. Elemental analysis of a colorless liquid has given its formula as C_5H_{10}. You recognize that this could be either a cycloalkane or an alkene. A chemical test to determine the class to which this compound belongs involves adding bromine. Explain how this would allow you to distinguish between the two classes.

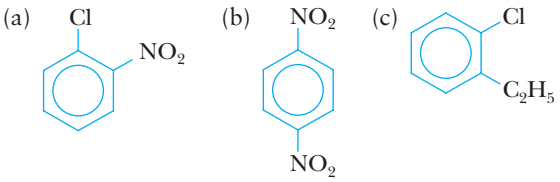
Aromatic Compounds

(See Section 23-2 and Example 23.5.)

31. Draw structural formulas for the following compounds:

(a) 1,3-dichlorobenzene (alternatively called *m*-dichlorobenzene)
(b) 1-bromo-4-methylbenzene (alternatively called *p*-bromotoluene)

32. Give the systematic name for each of the following compounds:



33. Write the equation for the reaction of 1,4-dimethylbenzene with CH_3Cl and $AlCl_3$. What is the structure and name of the single organic compound produced?

34. Write an equation for the preparation of hexylbenzene from benzene and other appropriate reagents.

35. Aromatic compounds react with a mixture of nitric and sulfuric acid to form aromatic compounds containing a nitro ($-NO_2$) group. Two isomeric compounds are formed by nitration of 1,2-dimethylbenzene. Draw the structures and name these compounds.

36. Nitration of toluene gives a mixture of two products, one with the nitro group ($-NO_2$) in the *ortho* position and one with the nitro group in the *para* position. Draw structures of the two products.

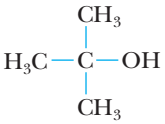
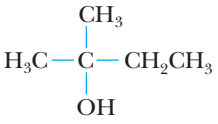
Alcohols, Ethers, and Amines

(See Section 23-3 and Example 23.6.)

37. Give the systematic name for each of the following alcohols, and tell if each is a primary, secondary, or tertiary alcohol:

(a) $CH_3CH_2CH_2OH$
(b) $CH_3CH_2CH_2CH_2OH$
(c)


(d)



38. Draw structural formulas for the following alcohols, and tell if each is primary, secondary, or tertiary:

(a) 1-butanol
(b) 2-butanol
(c) 3,3-dimethyl-2-butanol
(d) 3,3-dimethyl-1-butanol

39. Write the formula, and draw the structure, for each of the following amines:

(a) ethylamine
(b) dipropylamine
(c) butyldimethylamine
(d) triethylamine

40. Name the following amines:

(a) $CH_3CH_2CH_2NH_2$
(b) $(CH_3)_3N$
(c) $(CH_3)(C_2H_5)NH$
(d) $C_6H_{13}NH_2$

41. Draw structural formulas for the four possible alcohols with the formula $C_4H_{10}O$. Give the systematic name of each.

42. Draw structural formulas for all primary amines with the formula $C_4H_9NH_2$.

43. Complete and balance the following equations:

(a) $C_6H_5NH_2(\ell) + HCl(aq) \rightarrow$
(b) $(CH_3)_3N(aq) + H_2SO_4(aq) \rightarrow$

44. The structure of dopamine, a neurotransmitter, is given on page 923. Predict its reaction with aqueous hydrochloric acid.

45. Draw structures of the product formed by oxidation of the following alcohols. Assume an excess of oxidizing agent is used in each case.

(a) 2-methyl-1-pentanol
(b) 3-methyl-2-pentanol
(c) $HOCH_2CH_2CH_2CH_2OH$
(d) $H_2NCH_2CH_2CH_2OH$

46. Aldehydes and carboxylic acids are formed by oxidation of primary alcohols, and ketones are formed when secondary alcohols are oxidized. Give the name and formula for the alcohol that, when oxidized, gives the following products:

(a) $CH_3CH_2CH_2CHO$
(b) 2-hexanone

Compounds with a Carbonyl Group

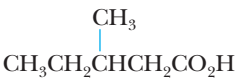
(See Section 23-4 and Example 23.7.)

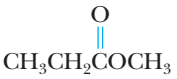
47. Draw structural formulas for (a) 2-pentanone, (b) hexanal, and (c) pentanoic acid.

48. Draw structural formulas for the following acids and esters:

(a) 2-methylhexanoic acid
(b) pentyl butanoate (which has the odor of apricots)
(c) octyl acetate (which has the odor of oranges)

49. Identify the class of each of the following compounds, and give the systematic name for each:

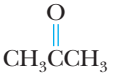
(a)


(b)


(c)

(d)

50. Identify the class of each of the following compounds, and give the systematic name for each:

(a)


(b)

(c)

51. Give the structural formula and systematic name for the organic product, if any, from each of the following reactions:

(a) pentanal and $KMnO_4$
(b) 2-octanone and $LiAlH_4$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

52. Give the structural formula and name for the organic product from the following reactions.

(a) $CH_3CH_2CH_2CH_2CHO + LiAlH_4$

(b) $CH_3CH_2CH_2CH_2OH + KMnO_4$

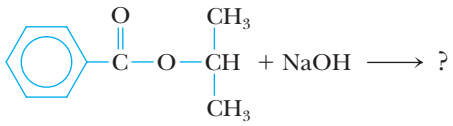
53. Describe how to prepare propyl propanoate beginning with 1-propanol as the only carbon-containing reagent.

54. Give the name and structure of the product of the reaction of benzoic acid and 2-propanol.

55. Draw structural formulas and give the names for the products of the following reaction:

$$CH_3\overset{\overset{O}{\|}}{C}OCH_2CH_2CH_2CH_3 + NaOH$$

56. Draw structural formulas, and give the names for the products of the following reaction:



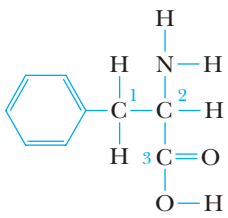
57. The structure of phenylalanine, one of the 20 amino acids that make up proteins, is drawn below (without lone pairs of electrons). The carbon atoms are numbered for the purpose of this question.

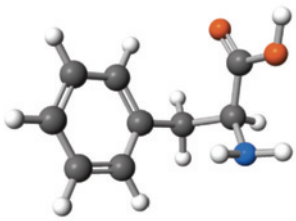
(a) What is the geometry of C_3?

(b) What is the O—C—O bond angle?

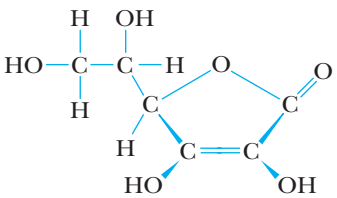
(c) Is this molecule chiral? If so, which carbon atom is chiral?

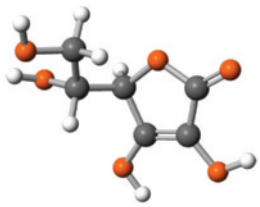
(d) Which hydrogen atom in this compound is acidic?





58. The structure of vitamin C, whose chemical name is ascorbic acid, is drawn below (without lone pairs of electrons).





(a) What is the approximate value for the O—C—O bond angle in the five-member ring?

(b) There are four OH groups in this structure. Estimate the C—O—H bond angles for these groups. Will they be the same value (more or less), or should there be significant differences in these bond angles?

(c) Is the molecule chiral? How many chiral carbon atoms can be identified in this structure?

(d) Identify the shortest bond in this molecule.

(e) What are the functional groups of the molecule?

59. What is the structure of the product from the reaction of butanoic acid and methylamine? To what class of compounds does this belong? Write a balanced chemical equation for the reaction.

60. The structure of acetaminophen is shown on page 930. Using structural formulas, write an equation for the reaction of an acid and an amine to form this compound.

Functional Groups

(See Section 23-4 and Example 23.7.)

61. Identify the functional groups in the following molecules.

(a) $CH_3CH_2CH_2OH$

(b) $H_3C\overset{\overset{O}{\|}}{C}NHCH_3$

(c) $CH_3CH_2\overset{\overset{O}{\|}}{C}OH$

(d) $CH_3CH_2\overset{\overset{O}{\|}}{C}OCH_3$

62. Consider the following molecules:

(1) $CH_3CH_2\overset{\overset{O}{\|}}{C}CH_3$

(2) $CH_3CH_2\overset{\overset{O}{\|}}{C}OH$

(3) $H_2C{=}CHCH_2OH$

(4) $CH_3CH_2\overset{\overset{OH}{|}}{C}HCH_3$

(a) What is the result of treating compound 1 with $NaBH_4$? What is the functional group in the product? Name the product.

(b) Draw the structure of the reaction product from compounds 2 and 4. What is the functional group in the product?

(c) What compound results from adding H_2 to compound 3? Name the reaction product.

(d) What compound results from adding NaOH to compound 2?

Polymers

(See Section 23-5 and Example 23.8.)

63. Polyvinyl acetate is the binder in water-based paints.
(a) Write an equation for its formation from vinyl acetate.
(b) Show a portion of this polymer with three monomer units.
(c) Describe how to make polyvinyl alcohol from polyvinyl acetate.

64. Neoprene (polychloroprene, a kind of rubber) is a polymer formed from the chlorinated butadiene $H_2C{=}CHCCl{=}CH_2$.
(a) Write an equation showing the formation of polychloroprene from the monomer.
(b) Show a portion of this polymer with three monomer units.

65. Polyacrylonitrile is a polymer of acrylonitrile, $CH_2{=}CHCN$. Write an equation for the synthesis of this polymer.

66. The structure of methyl methacrylate is given in Table 23.12. Draw the structure of a polymethyl methacrylate (PMMA) polymer that has four monomer units. (PMMA has excellent optical properties and is used to make hard contact lenses.)

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

67. Three different compounds with the formula $C_2H_2Cl_2$ are known.
(a) Two of these compounds are geometric isomers. Draw their structures.
(b) The third compound is a structural isomer of the other two. Draw its structure.

68. Draw the structure of 2-butanol. Identify the chiral carbon atom in this compound. Draw the mirror image of the structure you first drew. Are the two molecules superimposable?

69. An alkene having the formula C_6H_{12} is known to have a six-carbon chain. How many isomeric species can be drawn based on this description? List the names of these species.

70. Draw structures and name the four alkenes that have the formula C_4H_8.

71. Write equations for the reactions of *cis*-2-butene with the following reagents, representing the reactants and products using structural formulas.
(a) H_2O
(b) HBr
(c) Cl_2

72. Draw the structure and name the product formed if the following alcohols are oxidized. Assume an excess of the oxidizing agent is used. If the alcohol is not expected to react with a chemical oxidizing agent, write NR (no reaction).
(a) $CH_3CH_2CH_2CH_2OH$
(b) 2-butanol
(c) 2-methyl-2-propanol
(d) 2-methyl-1-propanol

73. Write equations for the following reactions, representing the reactants and products using structural formulas.
(a) The reaction of acetic acid and sodium hydroxide
(b) The reaction of methylamine with HCl

74. Write equations for the following reactions, representing the reactants and products using structural formulas.
(a) The formation of ethyl acetate from acetic acid and ethanol
(b) The hydrolysis of glyceryl tristearate (the triester of glycerol with stearic acid, a fatty acid; Table 23.9)

75. Write an equation for the formation of the following polymers.
(a) Polystyrene, from styrene ($C_6H_5CH{=}CH_2$)
(b) PET (polyethylene terephthalate), from ethylene glycol and terephthalic acid

76. Write equations for the following reactions, representing the reactants and products using structural formulas.
(a) The hydrolysis of the amide $C_6H_5CONHCH_3$ to form benzoic acid and methylamine
(b) The hydrolysis of $\text{+}CO(CH_2)_4CONH(CH_2)_6NH\text{+}_n$, (nylon-6,6, a polyamide) to give a carboxylic acid and an amine

77. Draw the structure of each of the following compounds:
(a) 2,2-dimethylpentane
(b) 3,3-diethylpentane
(c) 3-ethyl-2-methylpentane
(d) 3-ethylhexane

78. ▲ Structural isomers.
(a) Draw all of the isomers possible for C_3H_8O. Give the systematic name of each, and tell into which class of compound it fits.
(b) Draw the structural formulas for an aldehyde and a ketone with the molecular formula C_4H_8O. Give the systematic name of each.

79. ▲ Draw structural formulas for possible isomers of the dichlorinated propane, $C_3H_6Cl_2$. Name each compound.

80. Draw structural formulas for possible isomers with the formula C_3H_6ClBr, and name each isomer.

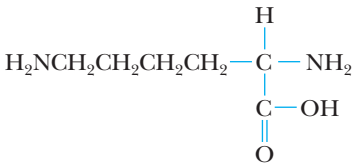
81. Give structural formulas and systematic names for the three structural isomers of trimethylbenzene, $C_6H_3(CH_3)_3$.

82. Give structural formulas and systematic names for possible isomers of dichlorobenzene, $C_6H_4Cl_2$.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

83. Voodoo lilies depend on carrion beetles for pollination. Carrion beetles are attracted to dead animals, and because dead and putrefying animals give off the horrible-smelling amine cadaverine, the lily likewise releases cadaverine (and the closely related compound putrescine, page 921). A biological catalyst, an enzyme, converts the naturally occurring amino acid lysine to cadaverine.



Lysine

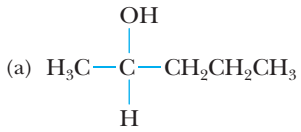
What group of atoms must be replaced in lysine to make cadaverine? (Lysine is essential to human nutrition but is not synthesized in the human body.)

84. Benzoic acid occurs in many berries. When humans eat berries, benzoic acid is converted to hippuric acid in the body by reaction with the amino acid glycine $H_2NCH_2CO_2H$. Draw the structure of hippuric acid, knowing it is an amide formed by reaction of the carboxylic acid group of benzoic acid and the amino group of glycine. Why is hippuric acid referred to as an acid?

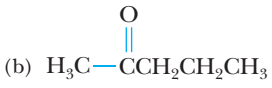
85. Consider the reaction of *cis*-2-butene with H_2 (in the presence of a catalyst).

(a) Draw the structure, and give the name of the reaction product. Is this reaction product chiral?
(b) Draw an isomer of the reaction product.

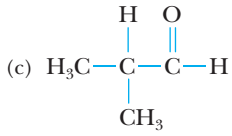
86. Give the name of each compound below, and name the functional group involved.



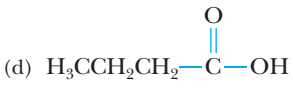
(a)



(b)



(c)



(d)

87. Draw the structure of glyceryl trilaurate, a fat. Lauric acid (page 789) has the formula $C_{11}H_{23}CO_2H$.

(a) Write an equation for the base hydrolysis of glyceryl trilaurate.
(b) Write an equation for the reaction that could be used to prepare biodiesel fuel from this fat.

88. A well-known company sells outdoor clothing made of recycled polyethylene terephthalate (PET), the principal material in many soft drink bottles. Another company makes PET fibers by treating recycled bottles with methanol to give the diester dimethyl terephthalate and ethylene glycol and then repolymerizes these compounds to give new PET. Write a chemical equation to show how the reaction of PET with methanol can give dimethyl terephthalate and ethylene glycol.

89. Identify the reaction products, and write an equation for the following reactions of $CH_2{=}CHCH_2OH$.

(a) H_2 (hydrogenation, in the presence of a catalyst)
(b) Oxidation (excess oxidizing agent)
(c) Addition polymerization
(d) Ester formation, using acetic acid

90. Write a chemical equation describing the reaction between glycerol and stearic acid (Table 23.9) to give glyceryl tristearate.

91. The product of an addition reaction of an alkene is often predicted by Markovnikov's rule.

(a) Draw the structure of the product of adding HBr to propene, and give the name of the product.
(b) Draw the structure and give the name of the compound that results from adding H_2O to 2-methyl-1-butene.
(c) If you add H_2O to 2-methyl-2-butene, is the product the same or different than the product from the reaction in part (b)?

92. There are three ethers with the formula $C_4H_{10}O$. Draw their structures.

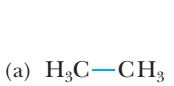
93. Review the introductory story about chocolate and then answer the following questions.

(a) How do theobromine and caffeine differ structurally?
(b) A 5.00-g sample of Hershey's cocoa contains 2.16% theobromine. What is the mass of the compound in the sample?

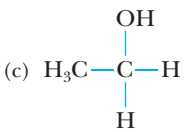
94. Nylon-6 is a polyamide formed by polymerizing $H_2NCH_2CH_2CH_2CH_2CH_2CO_2H$. Write an equation for this reaction.

In the Laboratory

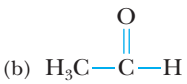
95. Which of the following compounds produces acetic acid when treated with an oxidizing agent such as $KMnO_4$?



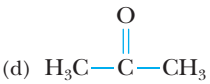
(a)



(c)



(b)

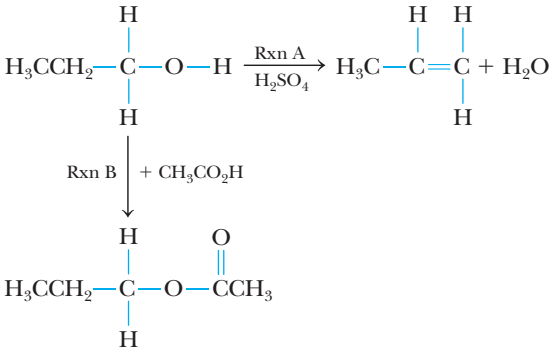


(d)

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

96. Consider the reactions of C_3H_7OH.



(a) Name the reactant C_3H_7OH.
(b) Draw a structural isomer of the reactant, and give its name.
(c) Name the product of reaction A.
(d) Name the product of reaction B.

97. You have a liquid that is either cyclohexene or benzene. When the liquid is exposed to dark-red bromine vapor, the vapor is immediately decolorized. What is the identity of the liquid? Write an equation for the chemical reaction that has occurred.

98. ▲ Hydrolysis of an unknown ester of butanoic acid, $CH_3CH_2CH_2CO_2R$, produces an alcohol A and butanoic acid. Oxidation of alcohol A forms an acid B that is a structural isomer of butanoic acid. Give the names and structures for alcohol A and acid B.

99. ▲ You are asked to identify an unknown colorless, liquid carbonyl compound. Analysis has determined that the formula for this unknown is C_3H_6O. Only two compounds match this formula.

(a) Draw structures for the two possible compounds.
(b) To decide which of the two structures is correct, you react the compound with an oxidizing agent and isolate from that reaction a compound that is found to give an acidic solution in water. Use this result to identify the structure of the unknown.
(c) Name the compound formed by oxidation of the unknown.

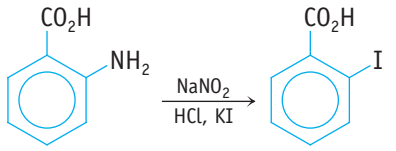
100. Describe a simple chemical test to tell the difference between $CH_3CH_2CH_2CH{=}CH_2$ and its isomer cyclopentane.

101. Describe a simple chemical test to tell the difference between 2-propanol and its isomer methyl ethyl ether.

102. ▲ An unknown ester has the formula $C_4H_8O_2$. Hydrolysis gives methanol as one product. Identify the ester, and write an equation for the hydrolysis reaction.

103. ▲ Addition of water to alkene X gives an alcohol Y. Oxidation of Y produces 3,3-dimethyl-2-pentanone. Identify X and Y, and write equations for the two reactions.

104. 2-Iodobenzoic acid, a tan, crystalline solid, can be prepared from 2-aminobenzoic acid. Other required reagents are $NaNO_2$ and KI (as well as HCl).

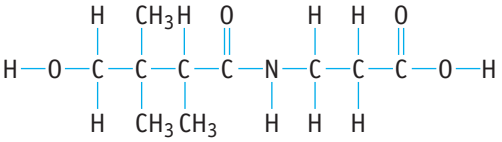


2-aminobenzoic acid **2-iodobenzoic acid**

(a) If you use 4.0 g of 2-aminobenzoic acid, 2.2 g of $NaNO_2$, and 5.3 g of KI, what is the theoretical yield of 2-iodobenzoic acid?
(b) Are other isomers of 2-iodobenzoic acid possible?
(c) You titrate the product in a mixture of water and ethanol. If you use 15.62 mL of 0.101 M NaOH to titrate 0.399 g of the product, what is its molar mass? Is it in reasonable agreement with the theoretical molar mass?

105. The transesterification reaction between PET and CH_3OH forms dimethyl terephthalate and ethylene glycol. If the methanol used in this reaction is labeled with oxygen-18 (^{18}O) in which of the products will the label be found?

106. Vitamin B-5, pantothenic acid, has the structure shown below. Base hydrolysis of this compound followed by acidification gives two compounds. Draw their structures.



Vitamin B-5, pantothenic acid

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

107. Carbon atoms appear in organic compounds in several different ways with single, double, and triple bonds combining to give an octet configuration. Describe the various ways that carbon can bond to reach an octet, and give the name and draw the structure of a compound that illustrates that mode of bonding.

108. There is a high barrier to rotation around a carbon–carbon double bond, whereas the barrier to rotation around a carbon–carbon single bond is considerably smaller. Use the orbital overlap model of bonding (Chapter 9) to explain why there is restricted rotation around a double bond.

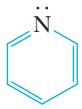
109. What important properties do the following characteristics impart to a polymer?

(a) Cross-linking in polyethylene
(b) The OH groups in polyvinyl alcohol
(c) Hydrogen bonding in a polyamide like nylon

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

110. One of the resonance structures for pyridine (C_5H_5N) is illustrated here. Draw another resonance structure for the molecule. Comment on the similarity between this compound and benzene.



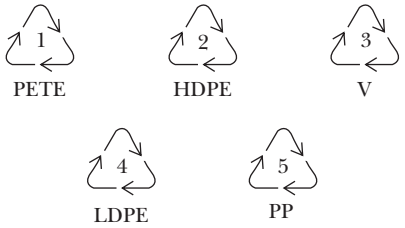
Pyridine

111. Write balanced equations for the combustion of ethane gas and liquid ethanol (to give gaseous products).

(a) Calculate the enthalpy of combustion of each compound. Which has the more negative enthalpy change for combustion per gram?

(b) If ethanol is assumed to be partially oxidized ethane, what effect does this have on the enthalpy of combustion?

112. Plastics make up about 20% of the volume of landfills. There is, therefore, considerable interest in reusing or recycling these materials. To identify common plastics, a set of universal symbols is now used, five of which are illustrated here. They symbolize low- and high-density polyethylene, polyvinyl chloride, polypropylene, and polyethylene terephthalate.



(a) Tell which symbol belongs to which type of plastic.

(b) Find an item in the grocery or drug store made from each of these plastics.

(c) Properties of several plastics are listed in the table. Based on this information, describe how to separate samples of these plastics from one another.

Plastic	Density (g/cm^3)	Melting Point (°C)
Polypropylene	0.92	170
High-density polyethylene	0.97	135
Polyethylene terephthalate	1.34–1.39	245

113. ▲ Maleic acid is prepared by the catalytic oxidation of benzene. It is a dicarboxylic acid; that is, it has two carboxylic acid groups.

(a) Combustion of 0.125 g of the acid gives 0.190 g of CO_2 and 0.0388 g of H_2O. Calculate the empirical formula of the acid.

(b) A 0.261-g sample of the acid requires 34.60 mL of 0.130 M NaOH for complete titration (so that the H ions from both carboxylic acid groups are used). What is the molecular formula of the acid?

(c) Draw a Lewis structure for the acid.

(d) Describe the hybridization used by the C atoms.

(e) What are the bond angles around each C atom?

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Najlah Feanny-Hicks/Corbis

Dolly the Sheep, the first cloned mammal.

Biochemistry

Chapter Outline

24-1 Proteins

24-2 Carbohydrates

24-3 Nucleic Acids

24-4 Lipids and Cell Membranes

24-5 Metabolism

ANIMAL CLONING The world was startled when it was announced that on July 5, 1996, a sheep named Dolly was born at the Roslin Institute at the University of Edinburgh in Scotland. What made Dolly so special was that she was not born in the normal way. Instead, she was the first clone, a genetically exact duplicate, of an adult mammal.

The process began when scientists led by Professor Ian Wilmut of the Roslin Institute took a mammary cell from a donor sheep and prepared its DNA so that it could be accepted by an egg from another sheep. The scientists then removed the DNA from the egg of the other sheep and replaced it with the DNA they had prepared. The egg developed and grew into an embryo. The embryo was then implanted into an adult female sheep who eventually gave birth to a normal lamb—Dolly. She went on to live a normal life, giving birth to lambs of her own. After living for six years, she eventually contracted a lung infection and had to be euthanized to prevent her from suffering further from this infection.

Chapter Goals

See Chapter Goals Revisited (page 973) for Study Questions keyed to these goals.

UNDERSTAND

- Structure determines the function of biological molecules.
- The process of protein synthesis.
- The RNA World hypothesis for the origin of life.
- The construction of a phospholipid bilayer and transport of materials across such a membrane.
- Coupling of ATP hydrolysis with a reactant-favored reaction can lead to a product-favored reaction.

DO

- Draw the structural formulas of common biochemical molecules.
- Predict the sequence of nucleotides complementary to a given strand of DNA.
- Predict the amino acid selected by a given sequence of three nucleotides in mRNA.

REMEMBER

- Proteins are condensation polymers of amino acids.
- The active site of an enzyme is the cleft or cavity where the substrate binds and the catalyzed chemical reaction takes place.
- DNA and RNA are condensation polymers of nucleotides.
- RNA undergoes hydrolysis much more quickly than DNA.
- The identity of some lipids.
- NAD^+ and NADH are involved in biochemical redox reactions.

Biotechnology has certainly progressed far since Watson and Crick first determined the structure of DNA in 1953. Though much remains to be discovered, we can now do things, such as cloning, that were only dreamed of in science fiction in the past. Such power, however, also brings with it ethical dilemmas. Even though it is currently banned by most countries, should cloning be expanded to humans? Unlike human cloning, animal cloning is permitted in the United States and the European Union as well as in many other countries in the world. Would farmers want clones of an animal well suited for food? Might researchers introduce a mutation into an animal so that it produces a particular compound in its blood or milk that could be used as a drug to treat a human illness and then clone the animal to get large quantities of the drug? Though currently unlikely due to practical limitations of present cloning technology, could we reintroduce a species that is extinct? Answering all of these questions and others will take the combined efforts of scientists, ethicists, politicians, and a well-informed populace.

This chapter will introduce you to the science behind some of the most important biological compounds and to some processes that occur in cells. This knowledge is essential to being able to understand the great strides being made in biotechnology today.

You are a marvelously complex biological organism, and so is every other living thing on Earth. What molecules are present in you, and what are their properties? How is genetic information passed from generation to generation? How does your body carry out the numerous reactions that are needed for life?

FIGURE 24.1 The human body with areas of interest to biologists, biochemists, and chemists.

These questions and many others fall into the realm of biochemistry, a rapidly expanding area of science. As the name implies, biochemistry exists at the interface of two scientific disciplines: biology and chemistry.

What separates a biochemist's perspective of biological phenomena from a biologist's perspective? The difference is becoming less distinct, but biochemists tend to concentrate on the specific molecules involved in biological processes and on how chemical reactions occur in an organism (Figure 24.1). They use the strategies of chemistry to understand processes in living things.

The goal of this chapter is to consider how chemistry is involved in answering important biological questions. To do so, we will examine four major classes of biological compounds: proteins, carbohydrates, nucleic acids, and lipids. We will also discuss chemical reactions that occur in living things, including some reactions involved in obtaining energy from food.

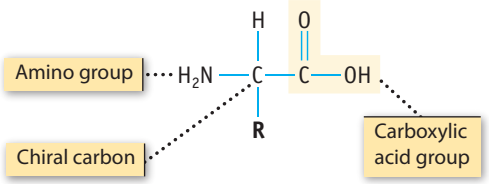
24-1 Proteins

Your body contains thousands of different proteins, and about 50% of the dry weight of your body consists of proteins. Proteins provide structural support (muscle, collagen), help organisms move (muscle), store and transport chemicals from one area to another (hemoglobin), regulate when certain chemical reactions will occur (hormones), and catalyze a host of chemical reactions (enzymes). All of these different functions and others are accomplished using this one class of compounds.

Amino Acids Are the Building Blocks of Proteins

Proteins are condensation polymers (◀ Section 23-5) formed from amino acids. **Amino acids** are organic compounds that contain an amino group ($—NH_2$) and a carboxylic acid group ($—CO_2H$)

Almost all amino acids that make up proteins are α-amino acids. In an α-amino acid, the amino group is at one end of the molecule, and the acid group is at the other end. In between these two groups, a single carbon atom (the α-carbon) has attached to it a hydrogen atom and either another hydrogen atom or an organic group, denoted R. Naturally occurring proteins are predominantly built using 20 amino acids, which differ only in the identity of the organic group, R. These organic groups can be nonpolar (groups derived from alkanes or aromatic hydrocarbons) or polar (with alcohol, acidic, basic, or other polar functional groups) (Figure 24.2). Depending on which amino acids are present, a region in a protein may be nonpolar, very polar, or anything in between.



All α-amino acids, except glycine, have four different groups attached to the α-carbon. The α-carbon is thus a chiral center (◀ Section 23-1), and two enantiomers exist. Interestingly, all of these amino acids occur in nature in a single

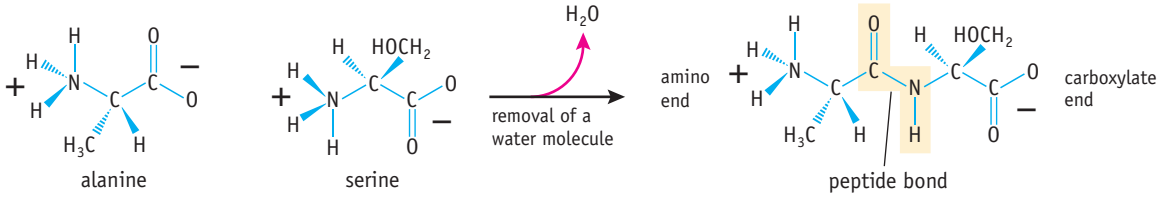

FIGURE 24.3 Formation of a peptide. Two α-amino acids condense to form an amide linkage, often called a *peptide bond*. Proteins are polypeptides, polymers consisting of many amino acid units linked through peptide bonds.

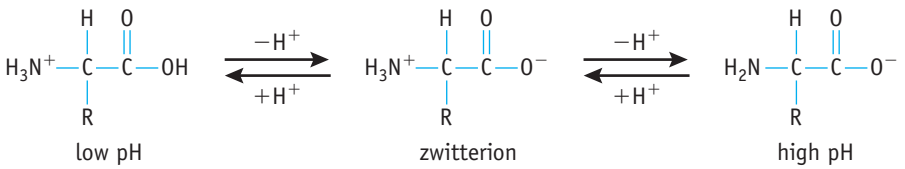
enantiomeric form—the form with the L-configuration (◀ *Case Study—An Awakening with L-DOPA*, p. 923).

Both the amino group and the carboxylic acid group can exist in two different states: an ionized form ($—NH_3^+$ and $—CO_2^-$) and an un-ionized form ($—NH_2$ and $—CO_2H$). At low pH, both groups will be in their protonated forms, that is, the amino group will be present as $—NH_3^+$ and the carboxylic acid group will be present as $—CO_2H$. As the pH is raised, the carboxylic acid group loses its proton and becomes the ionized form ($—CO_2^-$). The resulting species, which is the form prevalent in an aqueous environment at physiological pH (about 7.4), contains both a positive and a negative charge and is called a **zwitterion**. At higher pH values, the amino group loses its ionizable proton and becomes the un-ionized form ($—NH_2$).



The pH behavior of amino acids that have acidic or basic *R* groups is more complicated.

A condensation reaction between two amino acids results in the elimination of water and the formation of an amide linkage (Figure 24.3). The amide linkage in proteins is often referred to as a **peptide bond**, and the polymer (the protein) is called a **polypeptide**. The amide linkage is planar (◀ Section 23-4), and both the carbon and the nitrogen atoms are sp^2 hybridized. There is partial double-bond character in the C—O and C—N bonds, leading to restricted rotation about the carbon–nitrogen bond. As a consequence, each peptide bond in a protein is rigid and planar, a feature that plays a role in determining its structure.

Proteins consist of one or more polypeptide chains that are often hundreds of amino acids long. Their molar masses are thus often thousands of grams per mole.

EXAMPLE 24.1

Drawing Peptide Structures

Problem Peptide and protein structures are drawn starting with the free amino group on the left and ending with the free carboxylic acid group on the right. Draw the Lewis structure for the tripeptide alanine-glycine-serine.

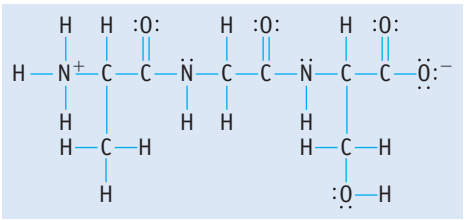
What Do You Know? You know the sequence of amino acids in the tripeptide, and that they are joined by amide linkages. The structures of the amino acids are listed in Figure 24.2.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Begin with the amino group of alanine on the left. Connect it via an amide linkage to glycine and then connect glycine to serine by another amide linkage.

Solution The Lewis structure for this tripeptide is



Think about Your Answer A tripeptide contains three amino acids and two peptide bonds. The zwitterionic form of the tripeptide was shown as this is the form present at physiological pH.

Check Your Understanding

Draw the Lewis structure for the tripeptide glycine-phenylalanine-valine.

Protein Structure and Hemoglobin

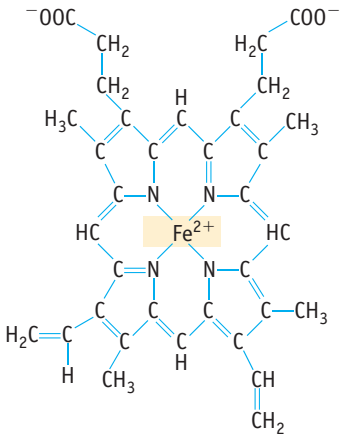
With this basic understanding of amino acids and peptide bonds, let us examine some larger issues related to protein structure. One of the central tenets of biochemistry is that "structure determines function." In other words, what a molecule can do is determined by which atoms or groups of atoms are present and how they are arranged in space. It is not surprising, therefore, that much effort has been devoted to determining the structures of proteins.

To simplify their discussions, biochemists describe proteins as having different structural levels. Each level of structure can be illustrated using hemoglobin.

Hemoglobin is the molecule in red blood cells that carries oxygen from the lungs to all of the body's other cells. It is a large iron-containing protein, made up of more than 10,000 atoms and having a molar mass of 64,500 g/mol. Hemoglobin consists of four polypeptide segments: two identical segments called the α subunits containing 141 amino acids each and two other segments called the β subunits containing 146 amino acids each. The β subunits are identical to each other but different from the α subunits. Each subunit contains an iron(II) ion locked inside an organic ion called a **heme** unit (Figure 24.4). The oxygen molecules transported by hemoglobin bind to these iron(II) ions.

Let us focus on the polypeptide part of hemoglobin (Figure 24.5). The first step in describing a structure is to identify how the atoms are covalently linked together. This is called the **primary structure** of a protein, which is simply the sequence of amino acids linked together by peptide bonds. For example, a glycine unit can be followed by an alanine, followed by a valine, and so on.

The remaining levels of structure all deal with noncovalent (nonbonding) interactions—that is, intermolecular forces—between amino acids in the protein. The **secondary structure** of a protein refers to hydrogen bonding networks formed between amide linkages in the protein backbone (◀ Figure 23.18 for an example of interchain hydrogen bonding). Specifically, the carbonyl group of one amide linkage interacts with the amino hydrogen of another amide. Some regular patterns, such as helices, sheets, and turns, often emerge as a result of hydrogen bonding. In hemoglobin, the amino acids in large portions of the polypeptide chains arrange themselves into many helical regions.



heme
(Fe-protoporphyrin IX)

FIGURE 24.4 Heme. The heme unit in hemoglobin (and in myoglobin, a related protein) consists of an iron ion in the center of a porphyrin ring system. (For more information about the iron-containing heme group, see *A Closer Look: Hemoglobin: A Molecule with a Tetradentate Ligand,* on page 872.)

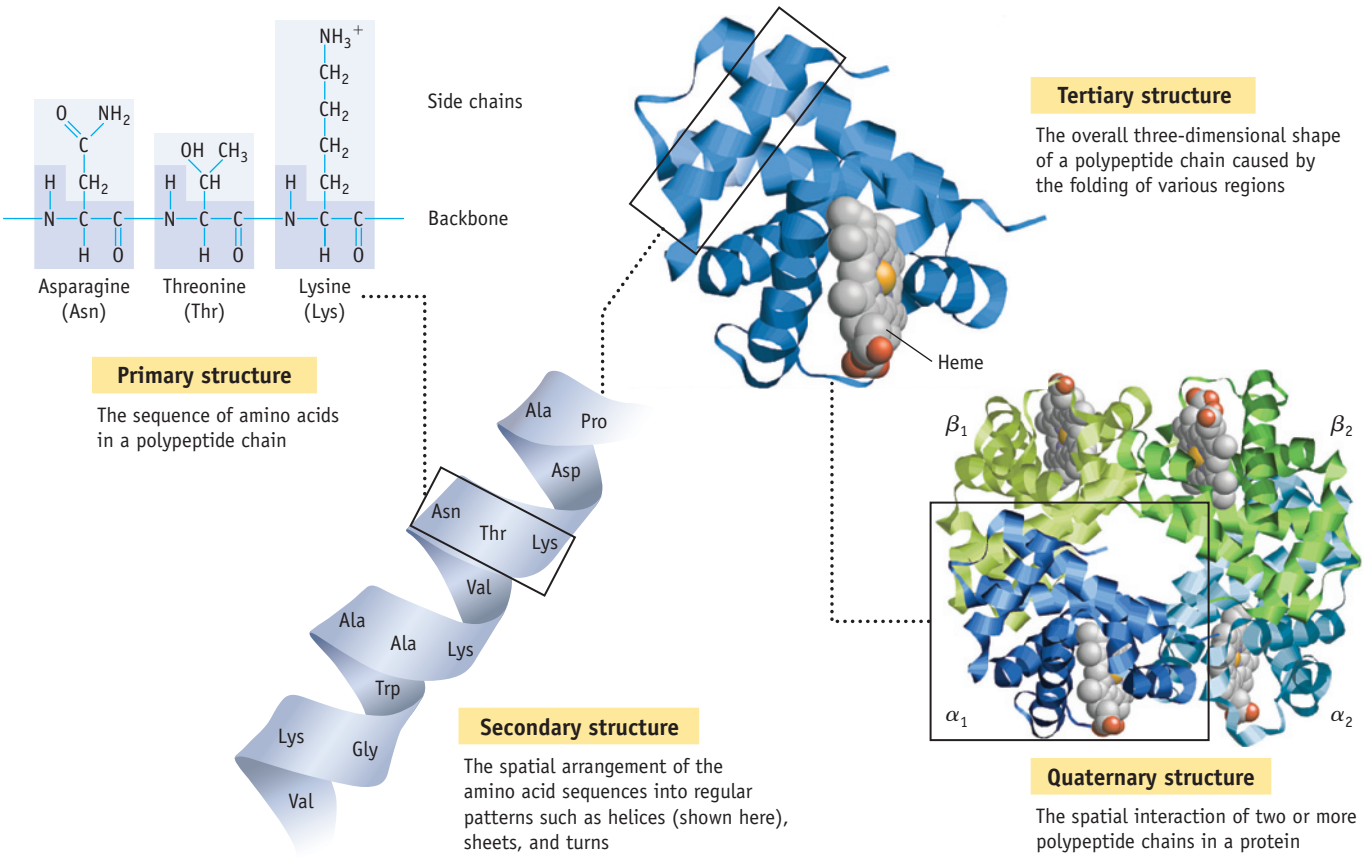

FIGURE 24.5 The primary, secondary, tertiary, and quaternary structures of hemoglobin.

The **tertiary structure** of a protein refers to how the chain is folded, including how amino acids far apart in the sequence interact with each other. In other words, this structure deals with how the regions of the polypeptide chain fold into the overall three-dimensional structure.

For proteins consisting of only one chain, the tertiary structure is the highest level of structure present. In proteins consisting of more than one polypeptide chain, such as hemoglobin, there is a fourth level of structure, called the **quaternary structure**. It is concerned with how the different chains interact. The quaternary structure of hemoglobin shows how the four subunits are related to one another in the overall protein.

The subtleties of sequence, structure, and function are dramatically illustrated in the case of hemoglobin. Seemingly small changes in the amino acid sequence of hemoglobin and other molecules can be important in determining function, as is illustrated by the disease called *sickle cell anemia*. This disease, which is sometimes fatal, affects some individuals of African descent. Persons affected by this disease are anemic; that is, they have low red blood cell counts. In addition, many of their red blood cells are elongated and curved like a sickle instead of being round disks (Figure 24.6a). These elongated red blood cells are more fragile than normal blood cells and thus often break, leading to the anemia that is observed. The elongated cells also do not fit through the capillaries properly and so block the flow of blood, thereby decreasing the amount of oxygen that the individual's cells receive.

The cause of sickle cell anemia has been traced to a small structural difference in hemoglobin. In the β subunits of the hemoglobin in individuals carrying the sickle cell trait, a valine has been substituted for a glutamic acid. An amino acid in this position ends up on the surface of the protein, where it is exposed to the aqueous environment of the cell. Glutamic acid and valine are quite different from each other. The side chain in glutamic acid is ionic, whereas that in valine is nonpolar. The nonpolar

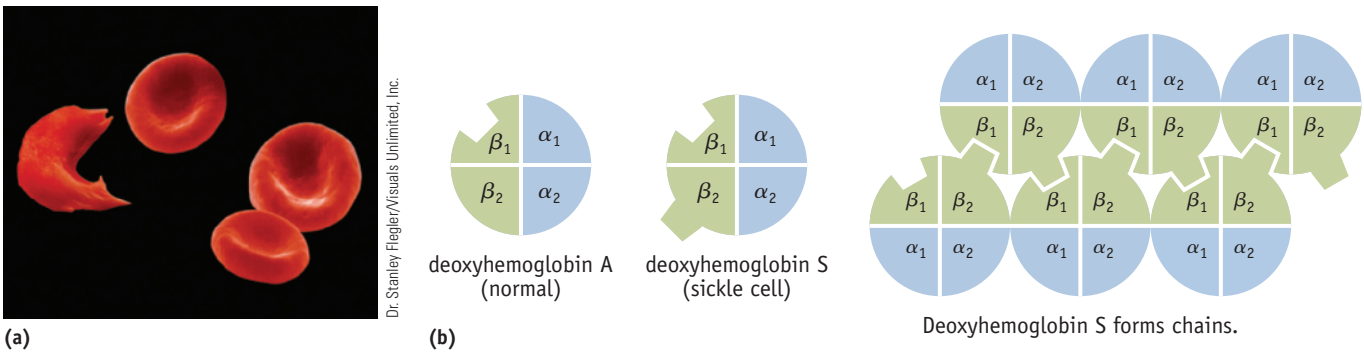

FIGURE 24.6 Normal and sickled red blood cells. (a) Red blood cells are normally rounded in shape, but people afflicted with sickle cell anemia have cells with a characteristic "sickle" shape. **(b)** Sickle cell hemoglobin has a nonpolar region that can fit into a nonpolar cavity on another hemoglobin. Sickle cell hemoglobins can link together to form long chainlike structures.

side chain on valine causes a nonpolar region to stick out from the molecule. When hemoglobin (normal or sickle cell) is in the deoxygenated state, it has a nonpolar cavity in another region. The nonpolar region around the valine on one sickle cell hemoglobin molecule fits nicely into this nonpolar cavity on another hemoglobin. The sickle cell hemoglobins thus link together, forming long chainlike structures (Figure 24.6b) that lead to the symptoms described.

Just one amino acid substitution in each β subunit causes sickle cell anemia! While other amino acid substitutions may not lead to such severe consequences, sequence, structure, and function are intimately linked and of crucial importance throughout biochemistry.

Enzymes, Active Sites, and Lysozyme

Many reactions necessary for life occur too slowly on their own, so organisms speed them up to the appropriate level using biological catalysts called **enzymes**. Almost every metabolic reaction in a living organism requires an enzyme, and most of these enzymes are proteins. Enzymes are often able to speed up reaction rates tremendously, typically 10^7 to 10^{14} times faster than uncatalyzed rates.

Enzyme Catalysis For more information about enzymes, see *Case Study: Enzymes—Nature's Catalysts* on p. 540.

For an enzyme to catalyze a reaction, several key steps must occur:

1. A reactant (often called the **substrate**) must bind to the enzyme.
2. The chemical reaction must take place.
3. The product(s) of the reaction must leave the enzyme so that more substrate can bind and the process can be repeated.

Typically, enzymes are very specific; that is, only a limited number of compounds (often only one) serve as substrates for a given enzyme, and the enzyme catalyzes only one type of reaction. The place in the enzyme where the substrate binds and the reaction occurs is called the **active site**. The active site often consists of a cavity or cleft in the structure of the enzyme into which the substrate or part of the substrate can fit. The R groups of amino acids or the presence of metal ions in an active site are often important factors in binding a substrate and catalyzing a reaction.

Lysozyme is an enzyme that can be obtained from human mucus and tears and from other sources, such as egg whites. Alexander Fleming (1881–1955) (who later discovered penicillin) is said to have discovered its presence in mucus when he had a cold. He purposely allowed some of the mucus from his nose to drip onto a dish containing a bacteria culture and found that some of the bacteria died. The chemical in the mucus responsible for this effect was a protein. Fleming called it *lysozyme* because it is an enzyme that causes some bacteria to undergo lysis (rupture).

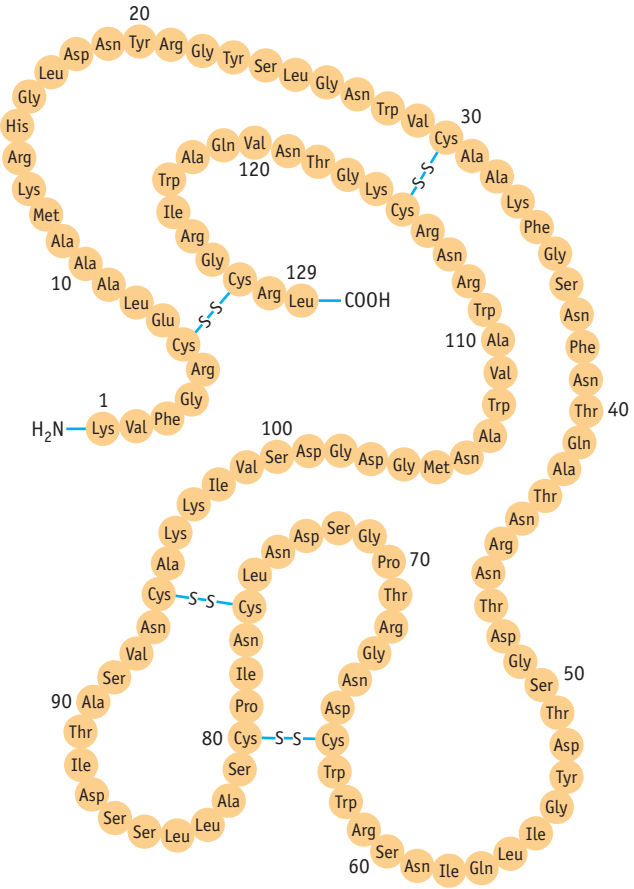

FIGURE 24.7 The primary structure of lysozyme. The cross-chain disulfide links (—S—S—) are links between cysteine amino acid residues.

Lysozyme is a protein containing 129 amino acids linked together in a single polypeptide chain (Figure 24.7). Its molar mass is 14,000 g/mol. As was true in the determination of the double-helical structure of DNA (◄ pages 332–333), x-ray crystallography and model building were key techniques used in determining lysozyme's three-dimensional structure and method of action.

Lysozyme's antibiotic activity results from its catalysis of a reaction that breaks down the cell walls of some bacteria. These cell walls contain a **polysaccharide**, a polymer of sugar molecules. This polysaccharide is composed of two alternating sugars: *N*-acetylmuramic acid (NAM) and *N*-acetylglucosamine (NAG). Lysozyme speeds up the reaction that breaks the bond between carbon-1 of NAM and carbon-4 of NAG (Figure 24.8), thereby breaking down the cell wall.

Lysozyme also catalyzes the breakdown of polysaccharides containing only NAG, but it is not very effective in cleaving molecules consisting of only two or three NAG units [$(NAG)_3$]. In fact, these molecules act as inhibitors of the enzyme. Researchers surmised that the inhibition resulted from these small molecules binding to but not completely filling the active site in the enzyme. X-ray crystallography of crystals of lysozyme that had been treated with $(NAG)_3$ revealed that $(NAG)_3$ binds to a cleft in lysozyme (Figure 24.9).

This cleft has room for a total of six NAG units. Molecular models of the enzyme and $(NAG)_6$ showed that five of the six sugars fit nicely into the cleft but that the fourth sugar in the sequence did not fit well. To get this fourth sugar into the active site, its structure has to be distorted. Assuming that the bond cleaved is the one connecting this fourth sugar to the fifth sugar, this distortion is advantageous because it deforms the molecule to more closely resemble the transition state of the cleavage reaction, thus speeding up this reaction. Amino acids immediately around this location can also assist in the cleavage reaction. In addition, models showed that if an alternating sequence of NAM and NAG binds to the enzyme in this cleft, NAM must bind to this fourth sugar location in the active site because it cannot fit into the third sugar-binding site, whereas NAG can. Cleavage must therefore occur only between carbon-1 of NAM and carbon-4 of the following NAG, not the other way around—and this is exactly what occurs.

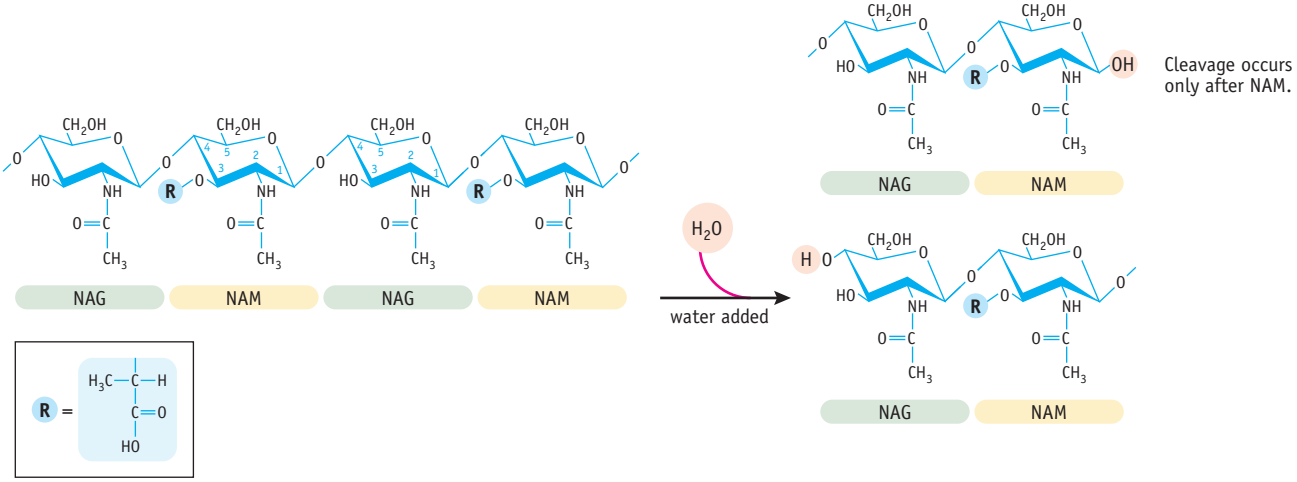

FIGURE 24.8 Cleavage of a bond between *N*-acetylmuramic acid (NAM) and *N*-acetylglucosamine (NAG). This reaction is accelerated by the enzyme lysozyme.

REVIEW & CHECK FOR SECTION 24-1

1. Proteins are made out of
   (a) amino acids
   (b) carbohydrates
   (c) nucleic acids
   (d) polyprotic acids
2. Under physiological conditions, amino acids are
   (a) fully protonated
   (b) fully deprotonated
   (c) zwitterionic
3. The secondary structure of a protein refers to
   (a) the sequence of amino acids in the protein
   (b) structures built from the hydrogen bonding network of the amide linkages in the protein's backbone
   (c) the overall three-dimensional structure of the protein
   (d) the arrangement of the different polypeptide strands in the protein

24-2 Carbohydrates

Carbohydrates, or sugars, constitute another major class of compounds found in living things. They serve as our fuel for life's many activities. Ribose and deoxyribose, two sugars, are components of the nucleic acids (► Section 24-3) that store and translate the genetic information in our cells. Polymers of sugars, polysaccharides, serve as structural molecules in plants and bacteria. Finally, sugar molecules linked to other biomolecules are involved in cell-cell interactions.

Monosaccharides

Carbohydrates are polyhydroxy aldehydes or ketones. The open-chain structures of glucose, a polyhydroxy aldehyde or *aldose*, and of fructose, a polyhydroxy ketone or *ketose*, are shown in Figure 24.10. Both glucose and fructose are examples of **monosaccharides**, which are the simplest sugars. Monosaccharides usually have the general formula $C_x(H_2O)_x$, and it is from this formula that this class of compounds derives its name of carbohydrate, a combination of carbon and water. Thus, the formula of glucose, $C_6H_{12}O_6$, is equivalent to $C_6(H_2O)_6$.

The most abundant sugars in nature contain five or six carbon atoms and are referred to as *pentoses* and *hexoses*, respectively. Ribose and deoxyribose (► Section 24-3), found in the nucleic acids RNA and DNA, are the most abundant

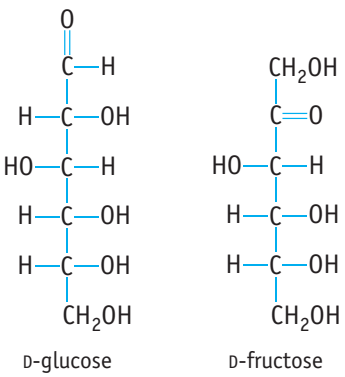

FIGURE 24.10 D-glucose and D-fructose. D-Glucose (an aldehyde) and D-fructose (a ketone) both have the molecular formula $C_6H_{12}O_6$.

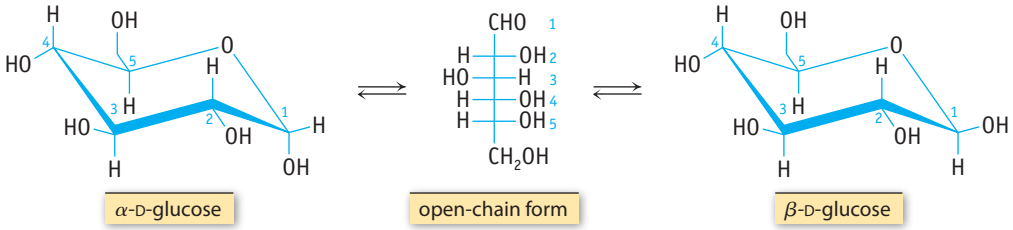

FIGURE 24.11 The straight-chain and ring forms of D-glucose.

pentoses in nature. By far, the most abundant six-carbon sugar containing an aldehyde group is glucose, and the most abundant six-carbon sugar containing a ketone group is fructose.

Almost all sugars are chiral, containing one or more carbon atoms with four different groups attached (◄ Section 23-1). In the chain structure of glucose, for example, four of the carbon atoms are bonded to four different groups. In nature, glucose occurs in just one of its enantiomeric forms; thus a solution of glucose rotates polarized light. The structures shown in Figure 24.10 are the D-isomers of glucose and fructose.

D-glucose exists in three different isomeric forms in aqueous solutions. Two of the isomers contain six-member rings, and the third is the open chain structure (Figure 24.11). Notice that the two ring structures differ by the orientation of the hydroxyl group and hydrogen atom at C-1. In α-D-glucose, the hydroxyl group is pointing down, whereas in β-D-glucose, it is pointing up. In aqueous solution, the three different forms of glucose rapidly interconvert, but the three different forms are not present in equal amounts. The straight chain isomer makes up less than 1% of the molecules with the cyclic forms predominating and present in a 63%:37% ratio of β-D-glucose to α-D-glucose. The predominant structures of most monosaccharides in aqueous solution contain rings.

Knowing the structure of glucose allows one to predict some of its properties. With five polar —OH groups in the molecule, glucose is, not surprisingly, soluble in water. The aldehyde group is susceptible to chemical oxidation to form a carboxylic acid, and detection of glucose (in urine or blood) takes advantage of this fact. Diagnostic tests for glucose involve oxidation with subsequent detection of the products.

Disaccharides

When two sugar molecules join together to form a **disaccharide**, they do so by means of a condensation reaction, in which a water molecule is lost. The two sugars end up connected to each other by a bridging oxygen atom; this type of bond between two sugar molecules is called a **glycosidic bond**. Table sugar, sucrose (Figure 24.12a), is

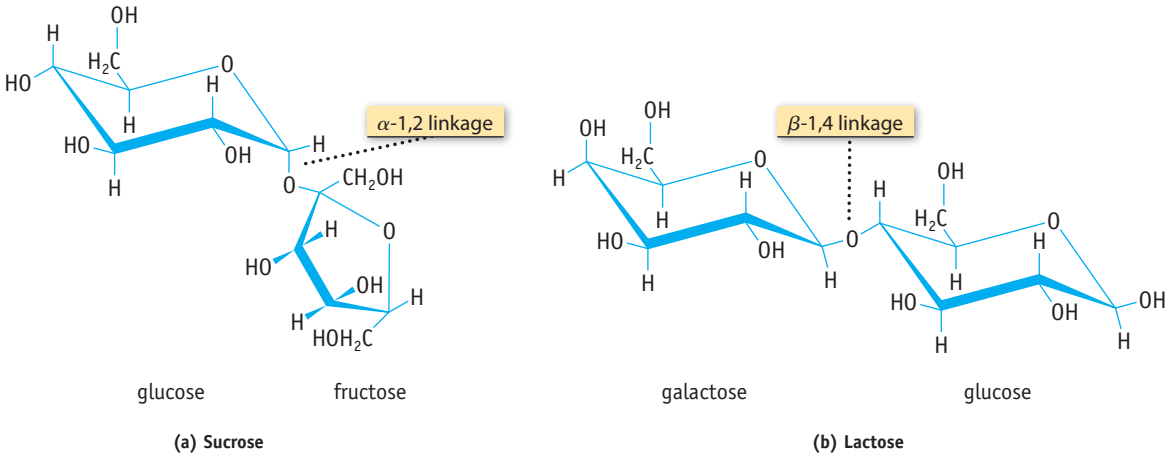

FIGURE 24.12 The disaccharides sucrose and lactose.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a disaccharide formed by the reaction of the hydroxyl group at position 1 in α-D-glucose with the hydroxyl group at position 2 of β-D-fructose. Because the hydroxyl group used in the first sugar (the glucose molecule) was in the α configuration, this type of linkage is referred to as an α-1,2 glycosidic bond.

Another common disaccharide is lactose (Figure 24.12b), a sugar found in milk. This sugar contains another hexose called β-D-galactose, which is combined with α-D-glucose by means of a β-1,4 linkage. When milk is consumed, lactose is broken down into its monosaccharides by utilizing an enzyme called lactase. As many humans grow older, their ability to produce lactase and thus digest lactose decreases; they are said to become lactose intolerant. In such individuals, the lactose is instead fermented by bacteria in the digestive tract into lactic acid, producing methane gas and hydrogen gas in the process. These gases can cause discomfort and lead to flatulence. In addition, the lactic acid and any undigested lactose can sometimes lead to diarrhea. These symptoms can certainly be avoided if the affected person abstains from dairy products, but they can also be avoided if a supplement containing the enzyme lactase is consumed along with the dairy products.

Polysaccharides

Long polymers of sugars, or **polysaccharides**, result when a large number of sugar molecules are joined by glycosidic bonds. In animal cells, excess glucose is stored as the polysaccharide called *glycogen* (Figure 24.13). The basic structure of glycogen is a branched chain of glucose molecules. Within a chain, the linkages are all α-1,4 glycosidic bonds. Branch points to the chain occur by means of α-1,6 glycosidic bonds. Branch points occur around every 10 or so glucose units in a chain.

Plant cells often store glucose in the form of starch. The chain lengths in starch are variable, ranging in size from molar masses of thousands to half a million g/mol. There are two main types of starch: *amylose starch* and *amylopectin starch*. Amylose starch contains linear chains of glucose molecules connected by means of α-1,4 glycosidic bonds. Amylopectin starch, like glycogen, is a branched chain of glucose molecules. The key difference is that the α-1,6 branch points in amylopectin occur less often than in glycogen, only every 30 or so glucose units.

Finally, the major structural molecule in plants, *cellulose*, is also a polysaccharide with chain lengths ranging from hundreds to many thousands of glucose units. The linkage between glucose molecules in cellulose is β-1,4 rather than α-1,4. This seemingly small change has a tremendous effect. Humans have enzymes that break down the α-1,4 linkages in starch but do not have an enzyme that breaks down the β-1,4 linkages between glucose molecules in cellulose. We can thus digest starch but cannot digest cellulose, and, when ingested, it passes through our systems unchanged as insoluble dietary fiber.

REVIEW & CHECK FOR SECTION 24-2

1. Glyceraldehyde is a monosaccharide with three carbon atoms. Its molecular formula is
   (a) $C_3H_3O_3$ (c) $C_3H_6O_3$
   (b) $C_3H_4O_2$ (d) $C_3H_6O_6$
2. The monomers of sucrose are
   (a) galactose and fructose (c) two molecules of fructose
   (b) glucose and fructose (d) two molecules of glucose
3. Which of the following cannot be digested by humans?
   (a) amylose starch (c) cellulose
   (b) amylopectin starch (d) sucrose

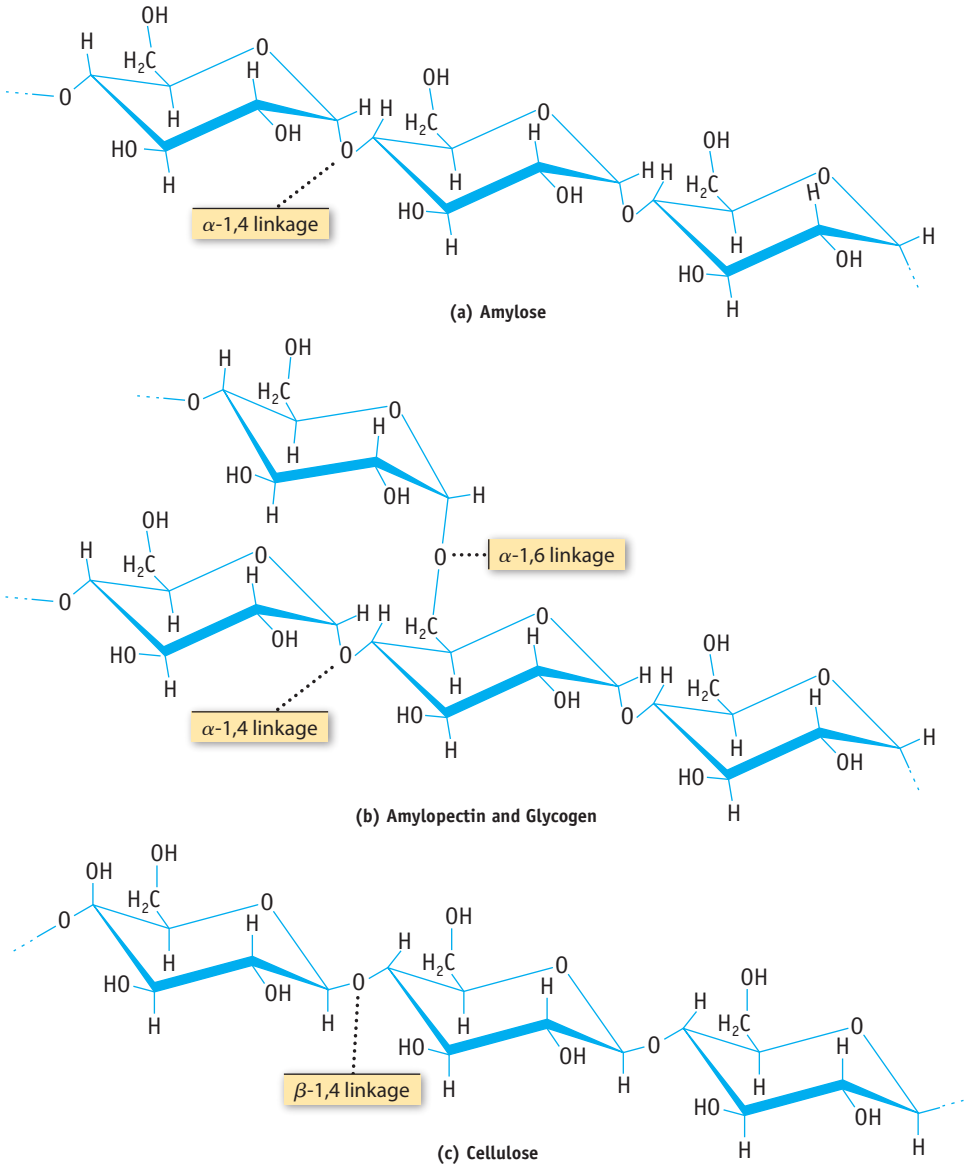

FIGURE 24.13 Polysaccharides.

24-3 Nucleic Acids

In the first half of the 20th century, researchers identified **deoxyribonucleic acid (DNA)** as the genetic material in cells. A close relative of DNA called **ribonucleic acid (RNA)** was also found in cells.

Nucleic Acid Structure

RNA and DNA are polymers (Figure 24.14). They consist of sugars having five carbon atoms (β-D-ribose in RNA and β-D-2-deoxyribose in DNA) that are connected by phosphodiester groups. At physiological pH, these phosphodiester linkages are in their ionized states with a net 1− charge per linkage. Thus, there is also a 1+ cation present per phosphodiester linkage (not shown in Figure 24.14). A phosphodiester group links the 3′ (pronounced "three prime") position of one sugar to the 5′ position of the next sugar. Attached at the 1′ position of each sugar is a nitrogen-containing (nitrogenous) base. The bases in DNA are adenine (A), cytosine (C), guanine (G), and thymine (T); in RNA, the nitrogenous bases are the same as in DNA, except that uracil (U) is used rather than thymine. A single sugar with a nitrogenous base attached is called a **nucleoside**. If a phosphate group is also attached, then the combination is called a **nucleotide** (Figure 24.15).

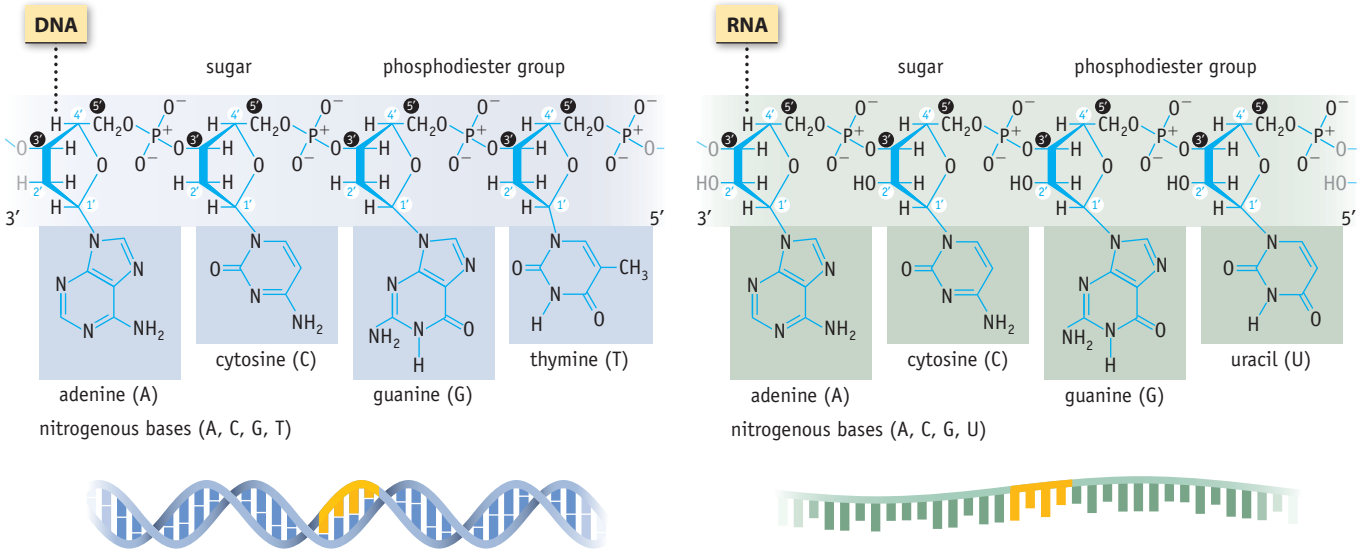

FIGURE 24.14 DNA and RNA.

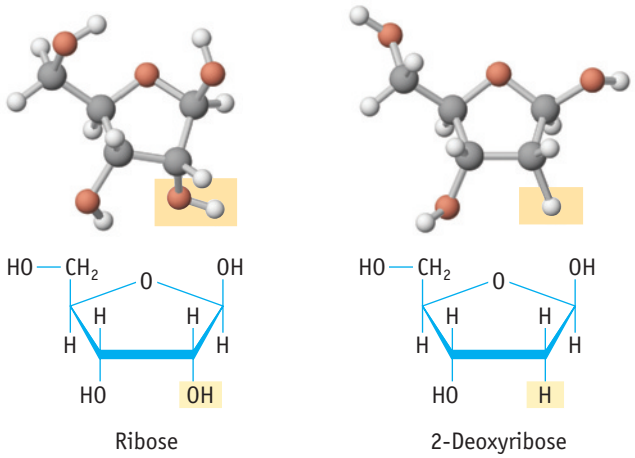
The principal chemical difference between RNA and DNA is the identity of the sugar.



Ribose has a hydroxyl group (—OH) at the 2 position, whereas 2-deoxyribose has only a hydrogen atom at this position. This seemingly small difference turns out to have profound effects. The polymer chain of RNA is cleaved many times faster than

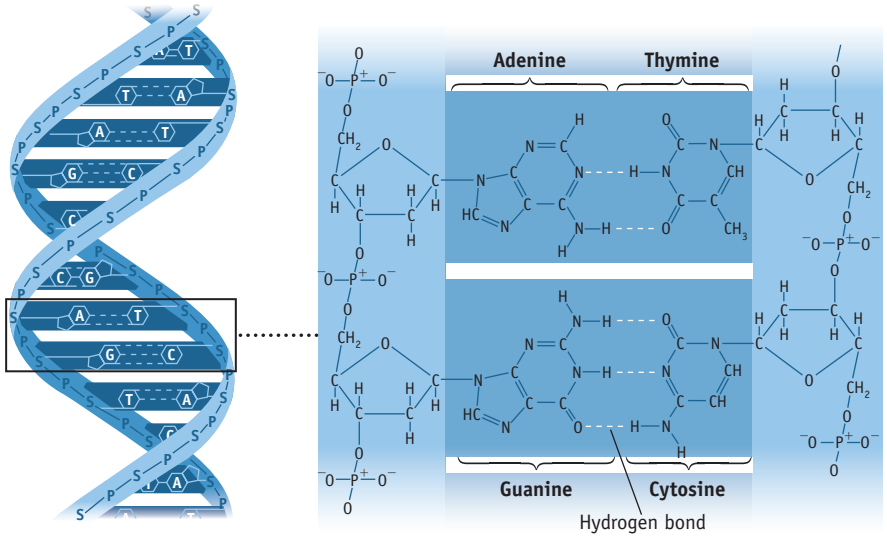

FIGURE 24.16 Base pairs and complementary strands in DNA. With the four bases in DNA, the usual pairings are adenine with thymine and cytosine with guanine. The pairing is promoted by hydrogen bonding.

a corresponding chain of DNA under similar conditions due to the involvement of this hydroxyl group in the cleavage reaction. The greater stability of DNA contributes to it being a better repository for genetic information.

How does DNA store genetic information? DNA consists of a double helix (Figure 24.16). In this structure, one strand of DNA is paired with another strand running in the opposite direction. Thus, if one strand is viewed from the 5′-end to the 3′-end, the other strand will be lined up next to it such that it runs from the 3′-end to the 5′-end. The key parts of the structure of DNA for storing genetic information are the nitrogenous bases. James Watson and Francis Crick (page 333) noticed that A can form two hydrogen bonds with T and that C can form three hydrogen bonds with G. The spacing between the two strands of the double helix is just right for either an A–T pair or for a C–G pair to fit, but other combinations (such as A–G) do not fit properly. Thus, if we know the identity of a nucleotide on one strand of the double helix, we can figure out which nucleotide must be bound to it on the other strand. The two strands are referred to as **complementary strands**.

The Structure of DNA For more information about the structure of DNA, see *Chemical Bonding in DNA* on p. 282, *Section 8-10: DNA, Revisited* on pp. 332–333, and *A Closer Look: Hydrogen Bonding in Biochemistry* on p. 414.

If the two strands are separated from each other, a new complementary strand can be constructed for each of the original strands by placing a G wherever there is a C, a T wherever there is an A, and so forth. Through this process, called **replication**, the cell ends up with two identical double-stranded DNA molecules for each molecule of DNA initially present. When the cell divides, each of the two resulting cells gets one copy of each DNA molecule (Figure 24.17). In this way, genetic information is passed along from one generation to the next.

The power of DNA was demonstrated further in 2010 in an experiment conducted by researchers at the J. Craig Venter Institute. They designed a sequence of DNA with a little over 1 million base pairs that was similar to that of a species of bacteria, *Mycoplasma mycoides*. Beginning with chemically synthesized strands of DNA that were only about one thousand base pairs long, they constructed the overall desired DNA sequence. They then replaced the DNA in cells of another species of bacteria, *M. capricolum,* with this synthesized DNA. The resulting organisms could perform cell division and grew into colonies of bacteria. These bacteria had characteristics not of *M. capricolum* but of the modified *M. mycoides*. The synthetic DNA, designed and constructed by humans, was not only capable of carrying out the normal functions of DNA but had transformed one species into another!

Two strands of DNA. Each base is paired with its partner: adenine (A) with thymine (T), guanine (G) with cytosine (C).

The two DNA strands are separated from each other.

Two new complementary strands are built using the original strands.

Replication results in two identical double-stranded DNA molecules.

At this stage during cell division, the chromosomes containing the DNA have been duplicated, and the two sets have been separated.

FIGURE 24.17 The main steps in DNA replication. The products of this replication are two identical double-helical DNA molecules. When a cell divides, each resulting cell gets one set.

EXAMPLE 24.2

Complementary Strands of DNA

Problem Nucleic acid sequences are usually written starting with the nucleotide on the 5′-end and proceeding to the 3′-end. A particular segment of a strand of DNA has the sequence AGTCCTCATG. What is the sequence of the complementary strand?

What Do You Know? You know the sequence of a segment of DNA and that in the complementary strand A will base pair with T, and C will base pair with G.

Strategy Write the sequence of DNA that is complementary to the given sequence by completing the base pairs (A with T and G with C). Make sure that in your final answer you list the sequence from the 5′-end to the 3′-end.

Solution The given sequence and it complement are as follows

Given sequence: 5′-AGTCCTCATG-3′

Complementary sequence: 3′-TCAGGAGTAC-5′

In order from the 5′-end to the 3′-end, this sequence is CATGAGGACT.

Think about Your Answer Knowing the sequence of one strand of DNA allows us to predict the sequence of DNA on the complementary strand.

Check Your Understanding

What is the sequence of the strand of DNA complementary to CGATACGTAC.

Protein Synthesis

The sequence of nucleotides in a cell's DNA contains the instructions to make the proteins the cell needs. DNA is the information storage molecule. To use this information, the cell first makes a complementary copy of the required portion of the DNA using RNA. This step is called **transcription**. The molecule of RNA that results is called **messenger RNA (mRNA)** because it takes this message to where

Table 24.1 Examples of the 64 Codons in the Genetic Code

Codon Base Sequence*	Amino Acid to Be Added
AAA	Lysine
AAC	Asparagine
AUG	Start
CAA	Glutamine
CAU	Histidine
GAA	Glutamic acid
GCA	Alanine
UAA	Stop
UAC	Tyrosine

*A = Adenine, C = cytosine, G = guanine, U = uracil.

protein synthesis occurs in the cell. The cell uses the more rapidly cleaved RNA rather than DNA to carry out this function.

It makes sense to use DNA, the more stable molecule, to store the genetic information because the cell wants this information to be passed from generation to generation intact. Conversely, it makes sense to use RNA to send the message to make a particular protein. By using the less-stable RNA, the message will not be permanent but rather will be destroyed after a certain time, thus allowing the cell to turn off the synthesis of the protein.

Protein synthesis occurs in **ribosomes**, complex bodies in a cell consisting of a mixture of proteins and RNA. The new protein is made as the ribosome moves along the strand of mRNA. The sequence of nucleotides in mRNA contains information about the order of amino acids in the desired protein. Following the signal in mRNA to start protein synthesis, every sequence of three nucleotides provides the code for an amino acid in the protein until the ribosome reaches the signal to stop (Table 24.1). These three-nucleotide sequences in mRNA are referred to as **codons**, and the correspondence between each codon and its message (start, add a particular amino acid, or stop) is referred to as the **genetic code**.

How is the genetic code used to make a protein? In the ribosome–mRNA complex, there are two neighboring binding sites, called the P site and the A site. (The ribosomes of eukaryotic cells, cells that contain nuclei, also have a third binding site, called the E site.) Each cycle that adds an amino acid to a growing protein begins with that part of the protein already constructed being located in the P site. The A site is where the next amino acid is brought in, and yet another type of RNA becomes involved at this point. This **transfer RNA (tRNA)** consists of a strand of RNA to which an amino acid can be attached (Figure 24.18). A strand of tRNA has a particular region that contains a sequence of three nucleotides that can attempt to form base pairs to a codon in the mRNA at the ribosome's A site. This three-nucleotide sequence in the tRNA is called the **anticodon**. Only if the base pairing between the codon and anticodon is complementary (for example, A with U) will the tRNA be

FIGURE 24.18 tRNA structure.

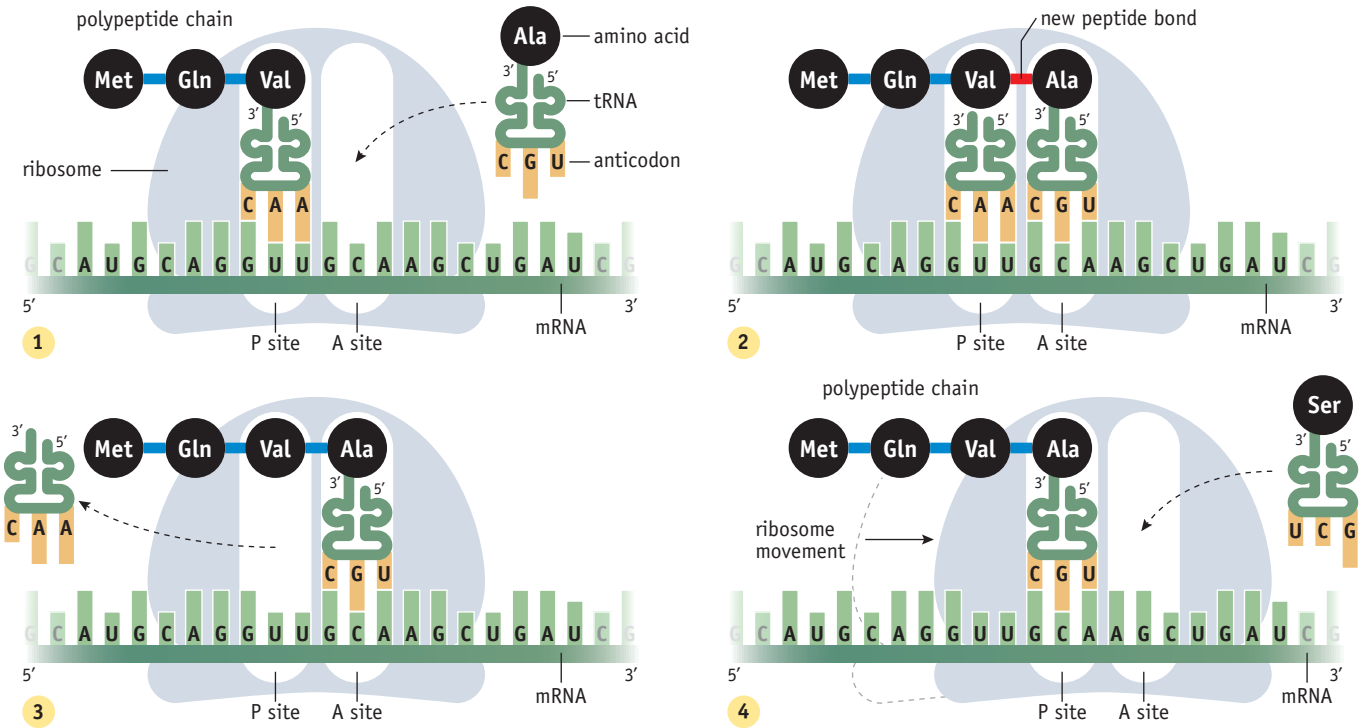

FIGURE 24.19 Protein synthesis. The tRNA with an anticodon complementary to the mRNA codon exposed in the A site of the ribosome brings the next amino acid to be added to the growing protein chain. After the new peptide bond is formed, the ribosome moves down the mRNA, exposing a new codon in the A site and transferring the previous tRNA and the protein chain to the P site.

able to bind to the mRNA–ribosome complex. Not only does the anticodon determine to which codon a particular strand of tRNA can bind, but it also determines which amino acid will be attached to the end of the tRNA molecule. Thus, a codon in the mRNA is complementary to a particular tRNA anticodon, which in turn specifies the correct amino acid.

The growing protein chain in the P site (Figure 24.19) reacts with the amino acid in the A site, resulting in the protein chain being elongated by one amino acid and moving the chain into the A site. The ribosome then moves down the mRNA chain, moving the tRNA along with the protein strand from the A site into the P site and exposing a new codon in the A site. The tRNA that had been in the P site and that no longer has an amino acid attached either leaves the ribosome directly or, if there is an E site present, moves into the E site before exiting from the ribosome. The process is then repeated.

Converting the information from a nucleotide sequence in mRNA into an amino acid sequence in a protein is called **translation**. Protein synthesis thus consists of two main processes: transcription of the DNA's information into RNA, followed by translation of the RNA's message into the amino acid sequence of the protein. There is more involved, but the processes of transcription and translation as discussed here provide a basic introduction to this important topic.

EXAMPLE 24.3

Protein Synthesis

Problem A strand of DNA that codes for three amino acids in a protein has the following sequence: TTT TGC GTA. What is the sequence of amino acids that will result from this sequence?

What Do You Know? The sequence of DNA is given. The information in DNA is transcribed into mRNA and then translated by tRNA into the desired amino acid sequence. You know the rules for forming base pairs. The genetic code for some of the codons in mRNA is given in Table 24.1.

Strategy From the given DNA sequence, determine the sequence of mRNA that would be transcribed. Look at the sequence of mRNA in groups of three nucleotides, which correspond to the codons. Determine which amino acids correspond to these codons.

Solution The given sequence of DNA and its complementary strand of mRNA are as follows:

Given sequence of DNA: 5′-TTT TGC GTA-3′

Complementary sequence of mRNA: 3′-AAA ACG CAU-5′

Thus the resulting strand of mRNA has the sequence 5′-UAC GCA AAA-3′. This strand of mRNA is divided into groups of three nucleotides each, corresponding to the codons in the mRNA. Based on Table 24.1 and reading from the 5′ end to the 3′ end, the amino acids selected by this sequence are tyrosine-alanine-lysine.

Think about Your Answer Keep in mind that the genetic code in Table 24.1 gives the mRNA codons and the amino acids brought in by the complementary tRNAs.

Check Your Understanding

What is the sequence of amino acids encoded by the DNA sequence TTG TGC TTT?

The RNA World and the Origin of Life

One of the most fascinating and persistent questions scientists pursue is how life arose on Earth. Plaguing those trying to answer this question is a molecular chicken-and-egg problem: Which came first, DNA or proteins? DNA is good at storing genetic information, but it is not good at catalyzing reactions. Proteins are good at catalyzing reactions, but they are not good at storing genetic information. In trying to picture an early self-replicating molecule, deciding whether it should be based on DNA or proteins seemed hopeless. Ultimately, both functions are important. These problems have caused some scientists to turn away from considering either DNA or proteins as candidates for the first molecule of life. One hypothesis that has gained support in recent years suggests that the first life on Earth may have been based on RNA instead.

Like DNA, RNA is a nucleic acid and can serve as a genetic storage molecule. We have already seen how it serves as an information molecule in the process of protein synthesis. In addition, scientists have discovered that retroviruses, like the human immunodeficiency virus (HIV) that causes AIDS, use RNA as the repository of genetic information instead of DNA. Perhaps the first organisms on Earth also used RNA to store genetic information.

In the 1980s, researchers discovered that particular strands of RNA catalyze some reactions involving cutting and joining together strands of RNA. Thomas Cech, a professor at the University of Colorado, Boulder, and Sidney Altman, a professor at Yale University, shared the 1989 Nobel Prize in Chemistry for their independent discoveries of systems that utilize "catalytic RNA." One might imagine that an organism could use RNA both as the genetic material and as a catalyst. Information and action are thus combined in this one molecule.

According to proponents of the "RNA World" hypothesis, the first organisms may have used RNA for both information and catalysis. At some later date, DNA

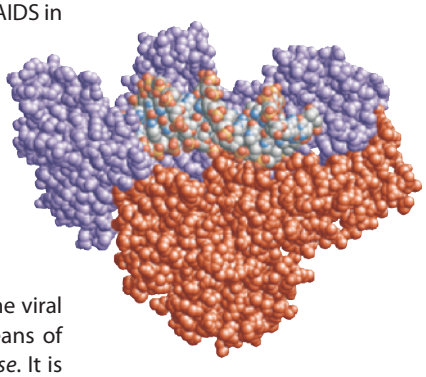
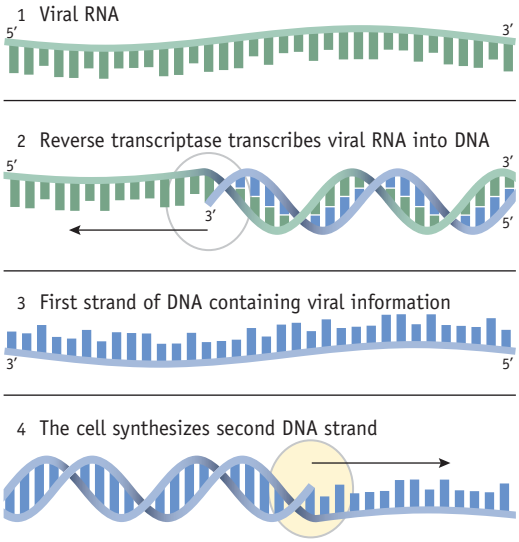
A CLOSER LOOK HIV and Reverse Transcriptase

One of the major health crises in modern times is the epidemic associated with the disease called *acquired immune deficiency syndrome* (AIDS). A person develops AIDS in the final stages of infection with the *human immunodeficiency virus* (HIV). At the time of this writing, an estimated 34 million people worldwide are infected with HIV, a retrovirus. Unlike all organisms and most viruses, a retrovirus uses single-stranded RNA rather than DNA as its genetic material.





Reverse transcriptase. The reverse transcriptase enzyme consists of two subunits (shown in red and purple). Reverse transcriptase catalyzes the transcription of viral RNA into DNA. The cell then constructs a complementary strand of DNA. The resulting double-stranded DNA is inserted into the cell's DNA.

During the course of infection, the viral RNA is transcribed into DNA by means of an enzyme called *reverse transcriptase*. It is so named because the direction of information flow is in the opposite direction (RNA $\rightarrow$ DNA) than that usually found in cells. The resulting DNA is inserted into the cell's DNA. The infected cell then produces the proteins and RNA to make new virus particles.

Reverse transcriptase consists of two subunits (see Figure). One subunit has a molar mass of approximately 6.6×10^4 g/mol, and the other has a molar mass of roughly 5.1×10^4 g/mol. Reverse transcriptase is not a very accurate enzyme, however. It makes an error in transcription for every 2000 to 4000 nucleotides copied. This is a much larger error rate than that for most cellular enzymes that copy DNA, which typically make one error for every 10^9 to 10^{10} nucleotides copied. The high error rate for reverse transcriptase contributes to the challenge scientists face in trying to combat HIV because these reverse transcription errors in the resulting DNA lead to frequent mutations in the virus. That is, the virus keeps changing, which means that developing a treatment that works and will continue to work is very difficult. Some treatments have been successful in significantly delaying the onset of AIDS, but none has yet proven to be a cure. More research is needed to combat this deadly disease.

evolved and had better information storage capabilities, so it took over the genetic information storage functions from RNA. Likewise, proteins eventually evolved and proved better at catalysis than RNA, so they took over this role for most reactions in a cell. RNA still plays a central role in the flow of genetic information, however. Genetic information does not go directly from DNA to proteins; it must pass through RNA along the way. Those favoring the RNA World hypothesis also point out that many enzyme cofactors, molecules that must be present for an enzyme to work, are RNA nucleotides or are based on RNA nucleotides. As we shall see, one of the most important molecules in metabolism is an RNA nucleotide, adenosine 5′-triphosphate (ATP). The importance of these nucleotides might date back to an earlier time when organisms were based on RNA alone.

REVIEW & CHECK FOR SECTION 24-3

1. Which breaks down more quickly in an aqueous solution?

   (a) DNA (b) RNA

2. What sequence of RNA is complementary to the DNA sequence AUG?

   (a) 5′-AUG-3′ (c) 5′-CAU-3′

   (b) 5′-CAT-3′ (d) 5′-TAC-3′

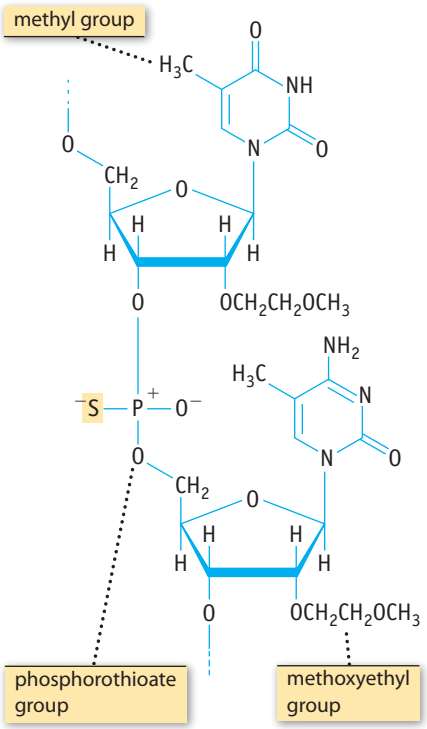
CASE STUDY

Antisense Therapy

Much traditional research in finding new drugs focuses on discovering compounds that bind to proteins involved in a disease. A different approach is followed by what is called "antisense" therapy. Rather than proteins, antisense therapy focuses on nucleic acids, specifically the mRNA or even the DNA coding for the protein in the first place. A compound is introduced that is complementary to this strand and that will therefore bind to it, thus tying up the strand of nucleic acid so that it will not deliver its message to the ribosome in the case of mRNA or will not be transcribed in the case of DNA. The sequence of the targeted nucleic acid is referred to as the "sense" strand and the complementary strand, the drug, is referred to as the antisense strand.

In 2013, a drug produced by Isis Pharmaceuticals became the second antisense compound approved by the Food and Drug Administration for human use in the United States. The drug, called Kynamro, targets the mRNA for a protein involved in a rare condition that leads to very high levels of cholesterol called *homozygous familial hypercholesterolemia*. (The first compound ever approved was produced by Isis in the late 1990s but was not commercially successful.)

Nucleic acid strands with natural phosphodiester linkages are very susceptible to enzyme breakdown in the body and thus do not make good drug candidates. Kynamro uses a backbone that contains phosphorothioate groups (Figure) in which an oxygen attached to phosphorus is replaced by a sulfur atom. In addition, the drug uses deoxyribose sugars in some locations and modified ribose sugars in other locations. In these ribose sugars, the 2′-OH group has been replaced by a methoxyethyl group. Yet another modification is that a methyl group has been added to each of the cytosine and uracil bases in the compound.



Part of the sequence of the antisense drug, Kynamro.

Kynamro may be just the beginning of what is likely to be many more antisense treatments; at the time of this writing, there were over 50 clinical drug studies under way for compounds from a variety of companies that utilize some form of gene silencing technology.

Questions:

1. Kynamro has the hydrogen bonding sequence: GCCUCAGTCTGCTTCGCACC. What is the sequence of nucleotides in the targeted mRNA?
2. The formula of Kynamro is $C_{230}H_{305}N_{67}O_{122}P_{19}S_{19}Na_{19}$. What is the molar mass of this compound?
3. What is the molecular geometry around the phosphorus atom in the phosphorothioate group?

Answers to these questions are available in Appendix N.

3. Which amino acid is selected by the mRNA codon GAA?

(a) alanine (c) histidine

(b) glutamic acid (d) tyrosine

24-4 Lipids and Cell Membranes

Lipids are another important type of compound found in organisms. Among other things, they are the principal components of cell membranes and a repository of chemical energy in the form of fat. In addition, some of the chemical messengers called **hormones** are lipids.

Lipids include a wide range of compounds because classification of a compound as a lipid is based on its solubility rather than on a particular chemical functional group. A lipid is a compound that is at best slightly soluble in water but is soluble in organic solvents.

Polar compounds tend to be soluble in a polar solvent such as water. Nonpolar compounds are soluble in nonpolar solvents but they tend not to be soluble in polar solvents. This tendency is sometimes referred to as "like dissolves like"

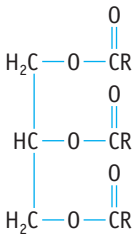
(◄ Section 13-2). Compounds in biological organisms that are nonpolar, or at least substantially nonpolar, have limited solubility in water and are therefore lipids.

A major category of lipids consists of molecules that have a polar end and a nonpolar end. The polar end provides the slight water affinity necessary for it to be compatible with being in the aqueous environment of the cell, but the nonpolar end greatly limits the solubility. Many of these compounds are fats, oils, fatty acids, or related to these compounds.

Fats and **oils** serve many functions in the body, a primary one being the storage of energy. Fats (solids) and oils (liquids) are triesters formed from glycerol (1,2,3-propanetriol) and three carboxylic acids that can be the same or different. Because they are triesters of glycerol, they are sometimes referred to as **triglycerides**.



Triglyceride. R = long chain fatty acid (Table 24.2)

The carboxylic acids in fats and oils are known as **fatty acids** and have a lengthy carbon chain, usually between 12 and 18 carbon atoms (Table 24.2). Fatty acids and triglycerides are lipids of the type where one end of the molecule is polar and the other end is nonpolar. The polar end in fatty acids is a carboxylic acid group, and the nonpolar end is a long hydrocarbon chain.

The hydrocarbon chains can be saturated (◄ Section 23-2) or may include one or more double bonds. Saturated compounds are more common in animal products while unsaturated fats and oils are more common in plants. In general, triglycerides containing saturated fatty acids are solids, and those containing unsaturated fatty acids are liquids at room temperature. The difference in melting point relates to the molecular structure. With only single bonds linking carbon atoms in saturated fatty acids, the hydrocarbon group is flexible, allowing the molecules to pack more closely together. This greater contact between the molecules leads to greater London dispersion forces between the molecules and thus to higher melting points. The double bonds in unsaturated triglycerides, on the other hand, introduce kinks that make the hydrocarbon group less flexible; consequently, the molecules pack less tightly together, leading to smaller London dispersion forces and lower melting points.

Table 24.2 Common Fatty Acids

Name	Number of C Atoms	Formula
Saturated Acids		
Lauric	C_{12}	$CH_3(CH_2)_{10}CO_2H$
Myristic	C_{14}	$CH_3(CH_2)_{12}CO_2H$
Palmitic	C_{16}	$CH_3(CH_2)_{14}CO_2H$
Stearic	C_{18}	$CH_3(CH_2)_{16}CO_2H$
Unsaturated Acid		
Oleic	C_{18}	$CH_3(CH_2)_7CH{=}CH(CH_2)_7CO_2H$

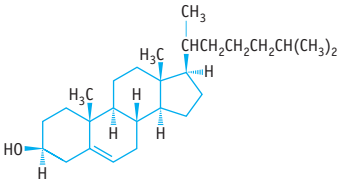
The ring structure present in all steroids three six member rings (A, B, and C) and one five-member ring (D).



cholesterol

FIGURE 24.20 Steroids.

Steroids are another category of lipids. Steroid molecules consist of four hydrocarbon rings joined together (Figure 24.20). Three of the rings contain six carbon atoms, and one contains five carbon atoms. Examples of steroids are the sex hormones testosterone, estradiol, and progesterone. Cholesterol (Figure 24.20) is also an important steroid. You may have heard of cholesterol because of its correlation with heart disease. While some cholesterol is necessary for humans, excess cholesterol can deposit in blood vessels, thus partially blocking them and causing the heart to work harder than it should.

The most prevalent molecules in most cell membranes are **phospholipids** (Figure 24.21a). These are similar to triglycerides in that they are based on glycerol. Two of the alcohol groups in glycerol are esterified to long-chain fatty acids. The third alcohol group is bonded to a phosphate that has another hydrocarbon chain attached to it. Phosphate groups are very polar. In phospholipid molecules, the phosphate end is sometimes called the "head," and the nonpolar hydrocarbon chains comprise the "tail."

When phospholipids are placed in water, they typically arrange themselves in a **bilayer structure** (Figure 24.21b). This is exactly the arrangement that phospholipids have in a cell membrane. Water is present on both the inside and the outside of the bilayer, corresponding to the inside and outside of the cell. In the outside layer of the membrane, the phospholipids line up alongside each other such that their polar heads face the aqueous environment outside the cell. Moving inward, next come the tails of these lipids. The phospholipids in the second layer align themselves so that their nonpolar tails are in contact with the outer layer's nonpolar tails. Finally, the polar heads of the second layer face the aqueous environment inside the cell. The phospholipid bilayer nicely encloses the cell and provides a good barrier between the inside and the outside of the cell, due to the different solubility characteristics of the nonpolar region in the middle of the bilayer.

There are other molecules present in cell membranes. Cholesterol is an important part of animal cell membranes, helping to give the membranes greater rigidity. Some proteins in the cell membrane allow select materials to cross from one side of the membrane to the other (*transport proteins*). Others accept chemical signals from other cells or respond to materials in the cell's environment (*receptor proteins*). Finally, some enzymes are also associated with the membrane.

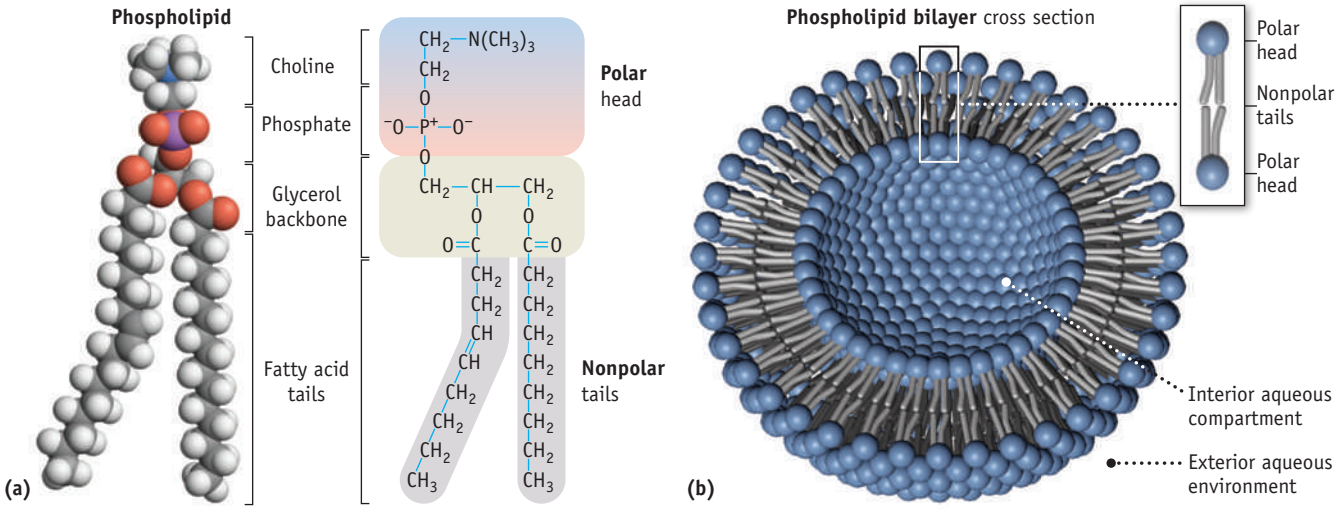


FIGURE 24.21 Phospholipids. (a) The structure of a phospholipid. **(b)** A cross-section of a phospholipid bilayer. The polar heads of the phospholipids are exposed to water, whereas the nonpolar tails are located in the interior of the bilayer.

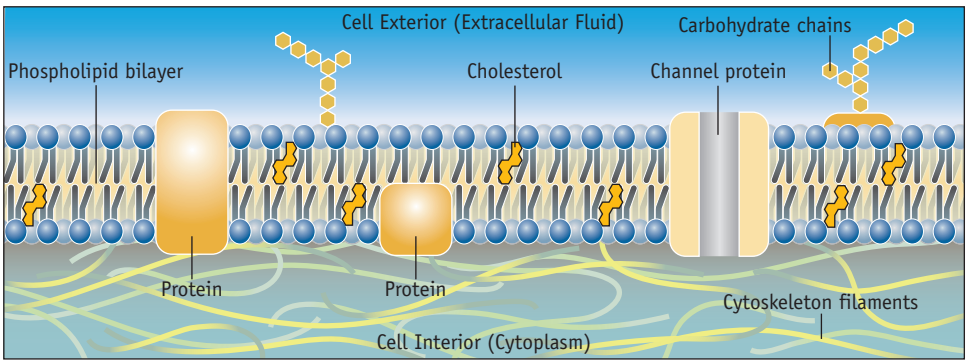

FIGURE 24.22 The fluid-mosaic model of cell membranes. A cell membrane is made up primarily of a phospholipid bilayer in which are embedded cholesterol, other lipids, and proteins. Movement within a layer occurs, but movement from one side of the bilayer to the other is rare.

The overall model for a cell membrane is called the **fluid-mosaic model** (Figure 24.22). In this model, the membrane's structure is largely that of a phospholipid bilayer. Embedded in this bilayer are molecules such as cholesterol and proteins. Movement of all of these components within each layer of the bilayer occurs readily; the membrane is thus fluid to a certain extent. On the other hand, there is little movement of components, such as phospholipids, from one side of the membrane to the other. The "like dissolves like" observation provides the reason for this lack of exchange between layers. The head of a phospholipid in the outer layer, for example, would not be compatible with the very nonpolar region within the bilayer that the phospholipid would need to pass through in order to traverse from one side of the bilayer to the other.

A cell membrane serves as the boundary between the cell and the rest of the universe, but exchange of some materials between the cell and the outside world needs to occur. There are different mechanisms by which this happens (Figure 24.23). The simplest is *passive diffusion*. In this process, a molecule moves through the phospholipid bilayer from a region of higher concentration to a region of lower concentration, the natural direction of flow. Because the bilayer provides such a

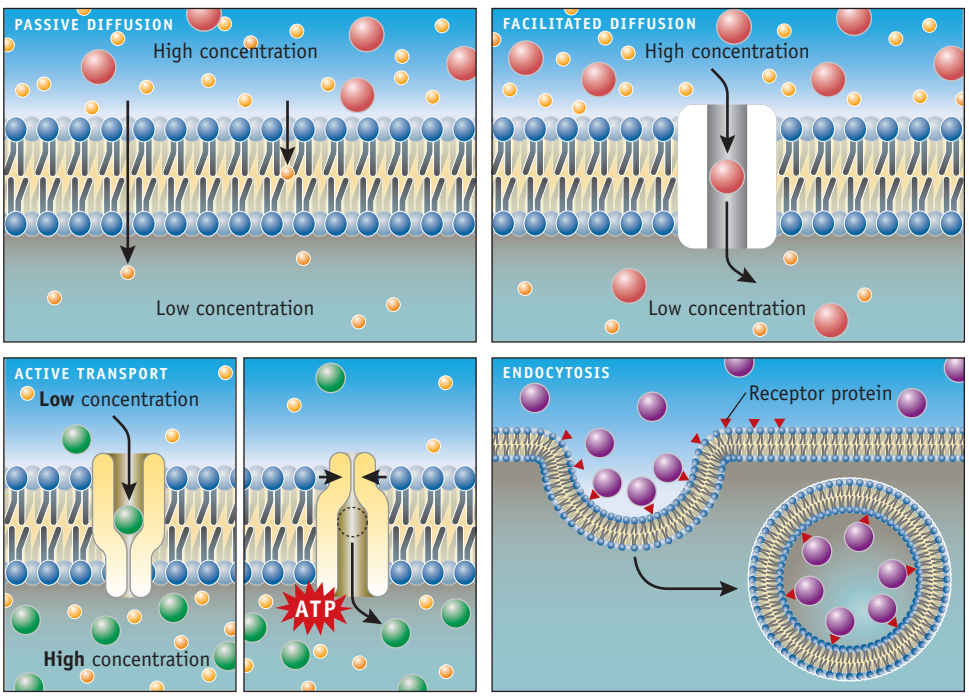

FIGURE 24.23 Transport of materials across a cell membrane.

good barrier, only a few very small uncharged molecules (such as N_2, O_2, CO_2, and H_2O) can pass through the membrane this way. Many more species enter or leave the cell through a process called *facilitated diffusion*. In this process, ions or molecules still travel from a region of higher concentration to a region of lower concentration, but they do not pass directly through the bilayer. Instead, they pass through channels formed by proteins embedded in the cell membrane.

Sometimes, it is necessary for the cell to move species from a region of lower concentration to a region of higher concentration, the opposite direction that would normally occur on its own. The cell accomplishes this by means of *active transport*. This is again mediated by transport proteins in the cell membrane. Because the species of interest must move in the opposite direction than it would normally go, the cell must expend energy in order to make this occur.

Finally, cells sometimes transport materials into themselves by means of *endocytosis*. This process is usually mediated by a receptor protein. The species of interest (called the *substrate*) binds to the receptor protein. A portion of the cell membrane surrounds the receptor–substrate complex. This portion of the cell membrane is then broken off, bringing the complex into the cell.

REVIEW & CHECK FOR SECTION 24-4

1. Which of the following is not an example of a lipid?

   (a) cholesterol (c) a fat

   (b) ethanol (d) an oil

2. In the fluid-mosaic model of the cell membrane, the phospholipids arrange themselves so as to have

   (a) polar heads pointing to the extracellular fluid

   (b) polar heads pointing to the intracellular fluid

   (c) polar heads pointing to both the extracellular fluid and the intracellular fluid

   (d) polar heads pointing to each other in the middle of the membrane

24-5 Metabolism

Why do we eat? Some components of our food, such as water, are used directly in our bodies. We break down other chemicals to obtain the molecular building blocks we need to make the many chemicals in our bodies. Oxidation of foods also provides the energy we need to perform the activities of life. The many different chemical reactions that foods undergo in the body to provide energy and chemical building blocks fall into the area of biochemistry called **metabolism**.

Energy and ATP

Substances in food, such as carbohydrates and fats, are oxidized in part of the metabolic process. These oxidations are energetically favorable reactions, releasing large quantities of energy. For example, the oxidation of the sugar glucose ($C_6H_{12}O_6$) to form carbon dioxide and water is very exothermic.

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

$$\Delta_r H° = -2803\ \text{kJ/mol-rxn}$$

However, rather than carry out this reaction in one rapid and exothermic step, a cell carries out a more controlled oxidation in a series of steps so that it can obtain the energy in small increments. In addition, it would be inefficient if every part of a cell needed to have all the mechanisms necessary to carry out the oxidation of every type

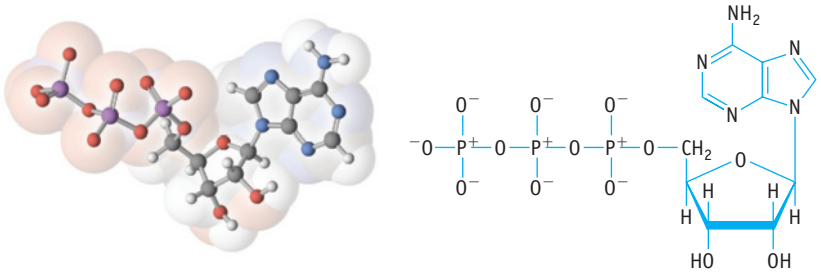

FIGURE 24.24 Adenosine-5′-triphosphate (ATP).

of molecule used for energy. Instead, it carries out the oxidation of compounds such as glucose in one location and stores the energy in a small set of compounds that can be used almost anywhere in the cell.

The principal compound used to perform this storage and transport of energy function is **adenosine 5′-triphosphate** (ATP). This ribonucleotide consists of a ribose molecule to which the nitrogenous base adenine is connected at the 1′ position and a triphosphate group is connected at the 5′ position (Figure 24.24). In aerobic respiration, the equivalent of 30–32 mol of ATP is typically produced per mole of glucose oxidized. Based on the ΔH values for the processes, a greater production of ATP might be expected, but the process is not completely efficient.

The hydrolysis of ATP to adenosine 5′-diphosphate (ADP) and inorganic phosphate (P_i) is an exothermic process that is product-favored at equilibrium (Figure 24.25).

$$ATP + H_2O \rightarrow ADP + P_i \qquad \Delta_r H° \approx -24 \text{ kJ/mol-rxn } (\Delta_r G°' = -30.5 \text{ kJ/mol-rxn})$$

$\Delta G°'$ For the definition of $\Delta G°'$, see *Case Study: Thermodynamics and Living Things* on p. 706.

Why is this reaction exothermic? In this reaction, we must break two bonds, a P—O bond in ATP and an H—O bond in water. But we also form two new bonds: a P—O bond connecting the phosphate group being cleaved off the ATP with the OH of the original water and an H—O bond connecting the hydrogen from the water with the portion of the ATP that forms ADP. In this overall process, more energy is released in forming these new bonds in the products than is required to break the necessary bonds in the reactants.

In cells, many chemical processes that would be reactant-favored on their own are linked with the hydrolysis of ATP. The combination of an energetically unfavorable process with the energetically favorable hydrolysis of ATP can yield a process that is energetically favorable and product-favored at equilibrium. For example, most cells have a greater concentration of potassium ions and a smaller concentration of sodium ions inside them than are present outside them. The natural tendency, therefore, is for sodium ions to flow into the cell and for potassium ions to flow out. To maintain the correct concentrations, the cell must counteract this movement and

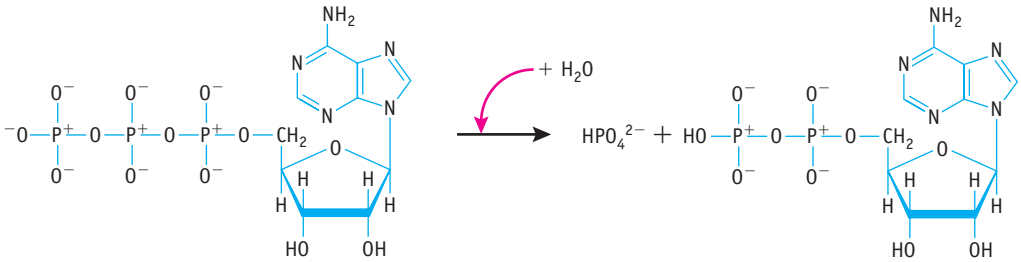

FIGURE 24.25 The exothermic conversion of adenosine-5′-triphosphate (ATP) to adenosine-5′-diphosphate (ADP).

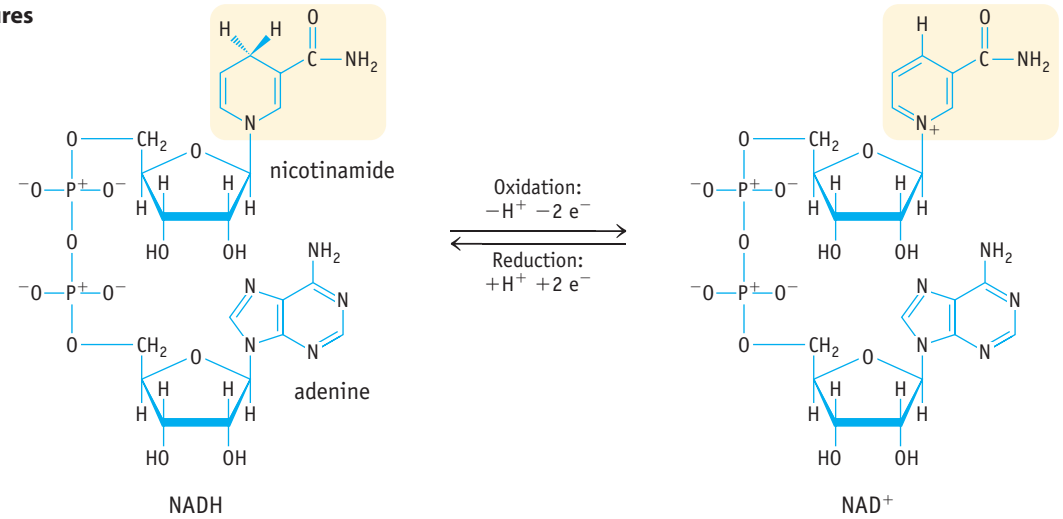

FIGURE 24.26 The structures of NADH and NAD^+.

pump sodium ions out of the cell and potassium ions into the cell. This requires energy. To accomplish this feat, the cell links this pumping process to the hydrolysis of ATP to ADP. The energy released from the hydrolysis reaction provides the energy to run a molecular pump (a transport protein) that moves the ions in the direction the cell needs.

Oxidation–Reduction and NADH

Cells also need compounds that can be used to carry out oxidation–reduction reactions. Just as ATP is a compound used in many biochemical reactions when energy is needed, so nature uses another small set of compounds to run many redox reactions. An important example is **nicotinamide adenine dinucleotide (NADH)**. This compound consists of two ribonucleotides joined at their 5′ positions via a diphosphate linkage. One of the nucleotides has adenine as its nitrogenous base, whereas the other has a nicotinamide ring (Figure 24.26). When NADH is oxidized, changes occur in the nicotinamide ring, such that the equivalent of a hydride ion (H^-) is lost. Because this hydride ion has two electrons associated with it, the nicotinamide ring loses two electrons in the process. The resulting species, referred to as NAD^+, is shown on the right in Figure 24.26.

In many biochemical reactions, when a particular species needs to be reduced, it reacts with NADH. The NADH is oxidized to NAD^+, losing two electrons in the process, and the species of interest is reduced by gaining these electrons. If a species must be oxidized, the opposite process often occurs; that is, it reacts with NAD^+. The NAD^+ is reduced to NADH, and the species of interest is oxidized.

Respiration and Photosynthesis

In the process of **respiration**, a cell breaks down molecules such as glucose, oxidizing them to CO_2 and H_2O.

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

The energy released in these reactions is used to generate the ATP needed by the cell. The sugars used in this process can be traced back to green plants, where sugars are made via the process of **photosynthesis**. In photosynthesis, plants carry out the reverse of glucose oxidation—that is, the synthesis of glucose from CO_2 and H_2O.

$$6\ CO_2(g) + 6\ H_2O(\ell) \rightarrow C_6H_{12}O_6(s) + 6\ O_2(g)$$

Green plants have found a way to use light to provide the energy needed to run this endothermic reaction.

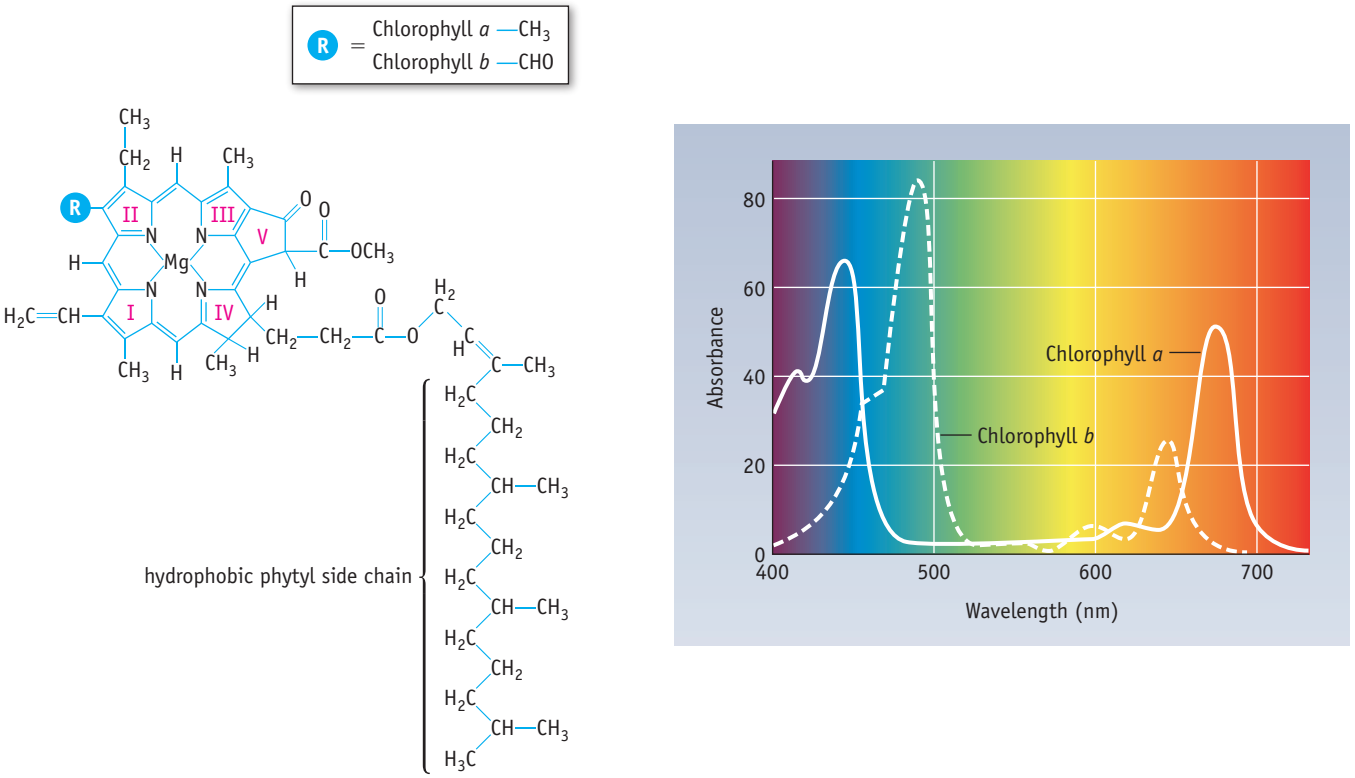

FIGURE 24.27 The structure of chlorophyll and the visible absorbance spectra of chlorophylls a and b.

The key molecule involved in trapping the energy from light in photosynthesis is chlorophyll. Green plants contain two types of chlorophyll: chlorophyll *a* and chlorophyll *b* (Figure 24.27). The absorbance spectra of chlorophyll *a* and chlorophyll *b* are also shown in Figure 24.27. Notice that these molecules absorb best in the blue-violet and red-orange regions of the visible spectrum. Not much light is absorbed in the green region. When white light shines on chlorophyll, red-orange and blue-violet light are absorbed by the chlorophyll; green light is reflected. We see the reflected light, so plants appear green to us. The light energy absorbed by the chlorophyll is used to drive the process of photosynthesis.

REVIEW & CHECK FOR SECTION 24-5

1. The hydrolysis of ATP is
   (a) endothermic and product-favored at equilibrium
   (b) endothermic and reactant-favored at equilibrium
   (c) exothermic and product-favored at equilibrium
   (d) exothermic and reactant-favored at equilibrium
2. The reduced form of nicotinamide adenine dinucleotide is
   (a) ADP (c) ATP
   (b) NAD^+ (d) NADH

APPLYING CHEMICAL PRINCIPLES

Polymerase Chain Reaction

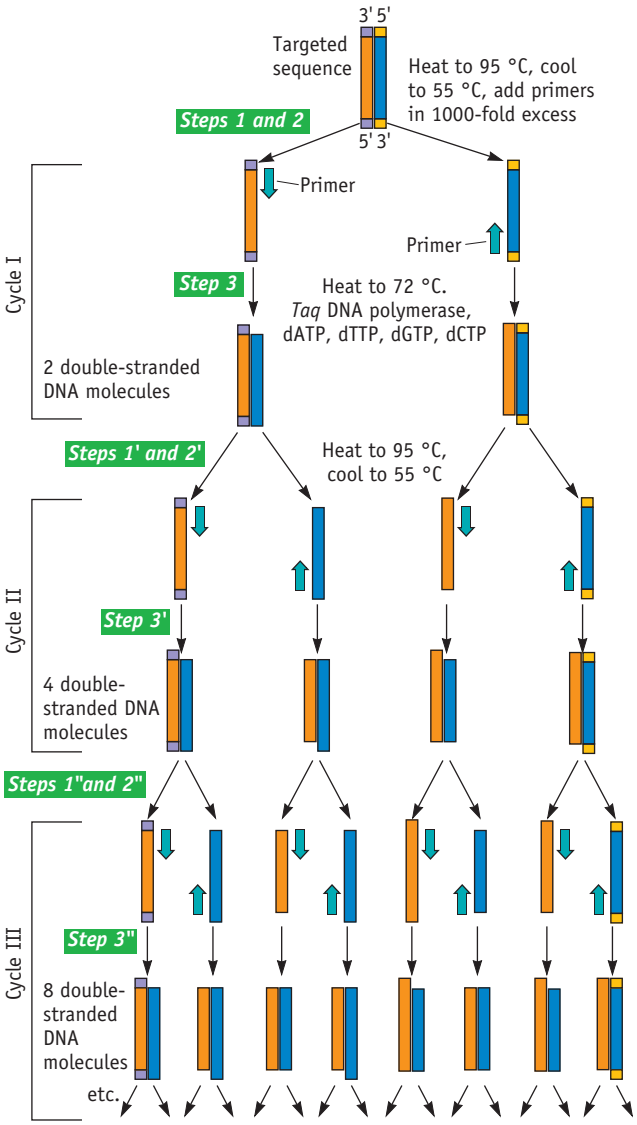
One night while driving to a cabin in Northern California, Kary Mullis, a chemist at the Cetus Corporation, was musing about how he might be able to develop a method to determine the sequence of a strand of DNA. As he worked on this problem, he realized that his musings had led him instead to a way to copy a sequence of DNA multiple times. Now called the *polymerase chain reaction* (PCR), the method allows one to amplify a segment of as little as a single copy of double-stranded DNA many times over in a relatively short period of time.

A piece of double-stranded DNA is heated to a temperature of around 95 °C. At this temperature, the hydrogen bonds holding the two strands together break, and the two strands separate from each other. The reaction mixture is then cooled to a lower temperature, around 55 °C. At this lower temperature, two small segments (usually 18–30 nucleotides long) of DNA called primers bind to the DNA, one primer per strand. One primer is complementary to the 3′-region of DNA to be amplified on one strand, and the other primer is complementary to the 3′-region of DNA to be amplified on the other strand. The temperature is then raised to around 72 °C where an enzyme called *Taq* polymerase becomes active. This polymerase, from a species of bacteria that lives at high temperature called *Thermus aquaticus (Taq)*, takes DNA nucleotide triphosphates (dATP, dGTP, dCTP, and dTTP) from the solution and adds them to the primers in the proper order so that new strands of DNA complementary to the original strands are produced. The process began with one double-stranded DNA, but two are now present at the end of the first cycle of PCR. The temperature is then raised again to 95 °C, and a new cycle is begun. After this second cycle, there will be four double-stranded DNAs present. After three cycles, the number will be eight, and so on with the amount of DNA growing exponentially. In this way, millions of copies of the original DNA can be made fairly quickly.

PCR has become commonplace in forensic science where it is used to amplify DNA found at a crime scene so that it can be tested against a suspect's DNA. It has also been used in tests for HIV infection, paternity tests, and for determining the DNA of organisms long extinct, as well as many other uses. Kary Mullis shared the Nobel Prize in Chemistry in 1983 for his work in developing this technique.

QUESTIONS:

1. Theoretically, how many copies of double-stranded DNA could be present after 20 cycles of PCR?
2. How does the fact that DNA molecules separate at 95 °C give evidence that the forces holding together DNA molecules are not covalent bonds?



PCR. Note that at the end of three cycles of PCR, eight copies of the segment of DNA exist.

3. Care must be exercised in selecting good primers to use in PCR.
   (a) Why are primers often chosen that have a high number of cytosines and guanines in their sequences?
   (b) Why would a primer sequence of CCCCCCCCCCGGGGGGGGGG not be a good choice?
   (c) Why is a vast excess of primer used for the amount of DNA to be amplified?

CHAPTER GOALS REVISITED

Now that you have studied this chapter, you should ask whether you have met the chapter goals. In particular, you should be able to:

UNDERSTAND

- Structure determines the function of biological molecules.
  - **a.** Understand the different levels of protein structure (primary, secondary, tertiary, and quaternary) (Section 24-1). Study Questions: 9, 10.
  - **b.** Recognize that one amino acid substitution in the structure of hemoglobin leads to sickle cell anemia (Section 24-1).
  - **c.** Understand that the structure of DNA leads to a method for replication of genetic information (Section 24-3).
- The process of protein synthesis (Section 24-3).
- The RNA World hypothesis for the origin of life (Section 24-3).
- The construction of a phospholipid bilayer and transport of materials across such a membrane (Section 24-4). Study Question: 19.
- Coupling of ATP hydrolysis with a reactant-favored reaction can lead to a product-favored reaction (Section 24-5). Study Question: 34.

DO

- Draw the structural formulas of common biochemical molecules.
  - **a.** Draw the Lewis structures for the most prevalent naturally-occurring amino acids (Section 24-1). Study Questions: 1–4.
  - **b.** Understand that under physiological conditions, amino acids exist as zwitterions in aqueous solution (Section 24-1). Study Questions: 1, 2.
  - **c.** Draw the Lewis structures for short polypeptides (Section 24-1). Study Questions: 5–8.
  - **d.** Draw the Lewis structures for commonly occurring mono-, di-, and polysaccharides (Section 24-2). Study Questions: 11, 12.
  - **e.** Recognize that amylose starch contains glucose molecules linked by α-1,4 glycosidic bonds, amylopectin starch and glycogen contain glucose molecules linked in chains containing α-1,4 glycosidic bonds with branch points made of α-1,6 glycosidic bonds, and cellulose contains chains of glucose linked by β-1,4 glycosidic bonds. (Section 24-2).
  - **f.** Draw the Lewis structures for short strands of DNA or RNA (Section 24-3). Study Questions: 15, 16.
- Predict the sequence of nucleotides complementary to a given strand of DNA (Section 24-3). Study Questions: 17, 18.
- Predict the amino acid selected by a given sequence of three nucleotides in mRNA (Section 24-3). Study Questions: 17, 18.

REMEMBER

- Proteins are condensation polymers of amino acids (Section 24-1).
- The active site of an enzyme is the cleft or cavity where the substrate binds and the catalyzed chemical reaction takes place (Section 24-1).
- DNA and RNA are condensation polymers of nucleotides (Section 24-3).
- RNA undergoes hydrolysis much more quickly than DNA (Section 24-3).
- The identity of some lipids (Section 24-4).
- NAD^+ and NADH are involved in biochemical redox reactions (Section 24-5).

Najlah Feanny-Hicks/Corbis

▲ denotes challenging questions.

Blue-numbered questions have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Proteins

(See Section 24-1 and Example 24.1.)

1. (a) Draw the Lewis structure for the amino acid valine, showing the amino group and the carboxylic acid group in their un-ionized forms.
(b) Draw the Lewis structure for the zwitterionic form of valine.
(c) Which of these structures will be the predominant form at physiological pH?

2. (a) Draw the Lewis structure for the amino acid phenylalanine, showing the amino group and the carboxylic group in their un-ionized forms.
(b) Draw the Lewis structure for the zwitterionic form of phenylalanine.
(c) Which of these structures will be the predominant form at physiological pH?

3. Consider the amino acids alanine, leucine, serine, phenylalanine, lysine, and aspartic acid. Which have polar R groups, and which have nonpolar R groups?

4. Consider the amino acids arginine, cysteine, glutamine, isoleucine, threonine, and tryptophan. Which have polar R groups, and which have nonpolar R groups?

5. Draw Lewis structures for the two dipeptides that contain both alanine and glycine.

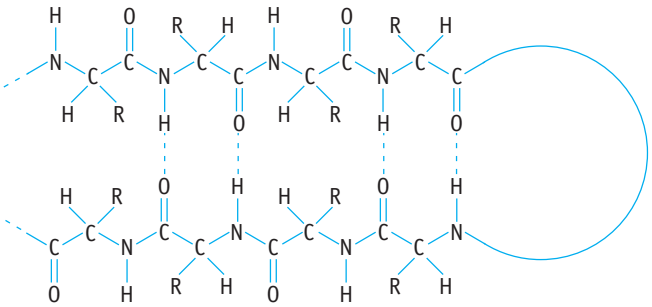
6. Do the amino acid sequences: valine-asparagine and asparagine-valine represent the same compound? Explain.

7. Draw the Lewis structure for the tripeptide serine-leucine-valine.

8. Draw the Lewis structure for the tripeptide tyrosine-histidine-glycine.

9. Identify the type of structure (primary, secondary, tertiary, or quaternary) that corresponds to the following statements.
(a) This type of structure is the amino acid sequence in the protein.
(b) This type of structure indicates how different peptide chains in the overall protein are arranged with respect to one another.
(c) This type of structure refers to how the polypeptide chain is folded, including how amino acids that are far apart in the sequence end up in the overall molecule.
(d) This type of structure deals with structures that arise from hydrogen bonding between amide groups in the protein's backbone.

10. The β-pleated sheet is a structure that commonly arises in proteins. Part of a β-pleated sheet is shown in the following figure. This type of structure is an example of which level of protein structure: primary, secondary, tertiary, or quaternary?



Carbohydrates

(See Section 24-2.)

11. Draw the structural formulas for α-D-glucose and β-D-glucose.

12. Draw the structural formula for two glucose molecules joined by a β-1,4 linkage.

Nucleic Acids

(See Section 24-3 and Examples 24.2 and 24.3.)

13. (a) Draw the structural formula for the sugar β-D-ribose.
(b) Draw the structural formula for the nucleoside adenosine (it consists of β-D-ribose and adenine).
(c) Draw the structural formula for the nucleotide adenosine 5′-monophosphate.

14. (a) Draw the structural formula for the sugar β-D-2-deoxyribose.
(b) Draw the structural formula for the nucleoside deoxyadenosine (it consists of β-D-2-deoxyribose and adenine).
(c) Draw the structural formula for the nucleotide deoxyadenosine 5′-monophosphate.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

15. Draw the structural formula for the tetranucleotide AUGC.

16. Draw the structural formula for the tetradeoxynucleotide CGTA.

17. Given the following nucleotide sequence in DNA: 5′—ACGCGATTC—3′:

(a) Determine the sequence of the complementary strand of DNA. Report this sequence by writing it from its 5′ end to its 3′ end.
(b) Write the sequence (5′–3′) for the strand of mRNA that would be complementary to the original strand of DNA.
(c) Assuming that this sequence is part of the coding sequence for a protein and that it is properly lined up so that the first codon of this sequence begins with the 5′ nucleotide of the mRNA, write the sequences for the three anticodons that would be complementary to this strand of mRNA.
(d) What sequence of amino acids is selected by this mRNA? (The complete genetic code is listed in several sites on the Internet.)

18. Given the following nucleotide sequence in DNA: 5′—TCGTAGGAT—3′:

(a) Determine the sequence of the complementary strand of DNA. Report this sequence by writing it from its 5′ end to its 3′ end.
(b) Write the sequence (5′–3′) for the strand of mRNA that would be complementary to the original strand of DNA.
(c) Assuming that this sequence is part of the coding sequence for a protein and that it is properly lined up so that the first codon of this sequence begins with the 5′ nucleotide of the mRNA, write the sequences for the three anticodons that would be complementary to this strand of mRNA.
(d) What sequence of amino acids is selected by this mRNA? (The complete genetic code is listed in several sites on the Internet.)

Lipids and Cell Membranes

(See Section 24-4.)

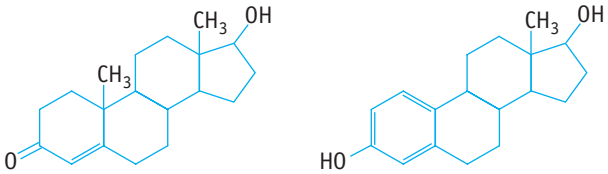
19. Sketch a section of a phospholipid bilayer in which you let a circle represent the polar head group and curvy lines represent the hydrocarbon tails. Label the regions of the bilayer as being polar or nonpolar.

20. If a drop of oleic acid is added to a dish of water, the oleic acid will spread out and form a layer that is one molecule thick on top of the water.

(a) Draw the Lewis structure for oleic acid.
(b) Label the region of the oleic acid molecule that is polar and the region that is nonpolar.
(c) In the layer of oleic acid that forms, which part of the oleic acid molecule points down into the water and which part points out of the water?

21. What structure do all steroids have in common?

22. The structures of the sex hormones testosterone (a male sex hormone) and estrogen (a female sex hormone) are shown below.



testosterone estrogen (estradiol)

(a) Compare these two structures.
(b) Are these molecules steroids? Explain.

Metabolism

(See Section 24-5.)

23. The section about metabolism provided a value for $\Delta_r H°$ for the oxidation of one mole of glucose (−2803 kJ/mol-rxn). Using $\Delta_f H°$ values at 25 °C, verify that this is the correct value for the equation

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

$$\Delta_f H°[C_6H_{12}O_6(s)] = -1273.3\ \text{kJ/mol}$$

24. The chemical equation for the fermentation of glucose into ethanol is

$$C_6H_{12}O_6(s) \rightarrow 2\ C_2H_5OH(\ell) + 2\ CO_2(g)$$

Using $\Delta_f H°$ values at 25 °C, calculate $\Delta_r H°$ for this reaction. (See Question 23 for $\Delta_f H°$ for glucose.)

25. Consider the following reaction:

$$NADH + H^+ + \tfrac{1}{2}\ O_2 \rightarrow NAD^+ + H_2O$$

(a) Which species (NADH, H^+, or O_2) undergoes oxidation?
(b) Which species undergoes reduction?
(c) Which species is the oxidizing agent?
(d) Which species is the reducing agent?

26. The body processes ethanol by first converting it to acetaldehyde in a reaction catalyzed by the enzyme alcohol dehydrogenase.

$$CH_3CH_2OH + NAD^+ \xrightarrow{\text{alcohol dehydrogenase}} CH_3CHO + NADH + H^+$$

In the body, acetaldehyde can cause headaches and nausea and is one of the causes of hangovers. Eventually, the acetaldehyde is oxidized to the acetate ion and then converted to carbon dioxide and water. In the reaction of ethanol with NAD^+, which species (ethanol or NAD^+) undergoes oxidation? Which species undergoes reduction?

General Questions

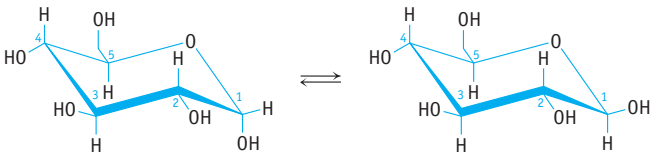
These questions are not designated as to type or location in the chapter. They may combine several concepts.

27. Draw two Lewis structures for the dipeptide alanine-isoleucine that show the resonance structures of the amide linkage.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

28. What is the equilibrium constant for the conversion of α-D-glucose to β-D-glucose in water at room temperature (assume that there is no glucose present in the open-chain structure)?



α-D-glucose 37% ⇌ β-D-glucose 63%

29. (a) Calculate the enthalpy change for the production of one mole of glucose by the process of photosynthesis at 25 °C. $\Delta_f H°$ [glucose(s)] = −1273.3 kJ/mol

$$6\ CO_2(g) + 6\ H_2O(\ell) \rightarrow C_6H_{12}O_6(s) + 6\ O_2(g)$$

(b) What is the enthalpy change involved in producing one molecule of glucose by this process?

(c) Chlorophyll molecules absorb light of various wavelengths. One wavelength absorbed is 650 nm. Calculate the energy of a photon of light having this wavelength.

(d) Assuming that all of this energy goes toward providing the energy required for the photosynthetic reaction, can the absorption of one photon at 650 nm lead to the production of one molecule of glucose, or must multiple photons be absorbed?

30. (a) According to the genetic code in Table 24.1, which amino acid is selected by the mRNA codon GAA?

(b) What is the sequence in the original DNA that led to this codon being present in the mRNA?

(c) If a mutation occurs in the DNA in which a G is substituted for the nucleotide at the second position of this coding region in the DNA, which amino acid will now be selected?

31. How many codons are possible? All of these codons are used in molecules of mRNA and there are only 20 amino acids normally encoded (plus start codons and stop codons). Is there exactly one codon per amino acid, must some codons select for more than one amino acid, or must there be some amino acids for which there is more than one codon?

32. There are $4^1 = 4$ mononucleotides of DNA, there are $4^2 = 16$ possible dinucleotides, and so on. If a segment of DNA were completely random, how many nucleotides long would it need to be in order to have one possible sequence for each person on Earth (currently about 7 billion people)?

33. In the process of respiration

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

which molecule undergoes oxidation? Which molecule undergoes reduction?

34. The first step of the metabolic process known as glycolysis is the conversion of glucose to glucose-6-phosphate This process has a positive value for $\Delta_r G°'$.

$$\text{Glucose} + P_i \rightarrow \text{Glucose-6-phosphate} + H_2O$$
$$\Delta_r G°' = +13.8\ \text{kJ/mol-rxn}$$

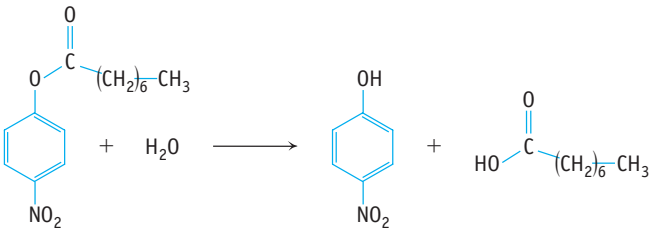
This reaction is coupled to the hydrolysis of ATP

$$ATP + H_2O \rightarrow ADP + P_i$$
$$\Delta_r G°' = -30.5\ \text{kJ/mol-rxn}$$

What is the sum of these two equations and the value of $\Delta_r G°'$ for the coupled reaction? Is the coupled reaction product-favored at equilibrium?

In the Laboratory

35. The enzyme lipase catalyzes the hydrolysis of esters of fatty acids. The hydrolysis of *p*-nitrophenyloctanoate was followed by measuring the appearance of *p*-nitrophenol in the reaction mixture:



p-nitrophenol

The following data were obtained at 30 °C:

Substrate Concentration (mol/L)	Reaction Rate (mol/L · min)
1.0×10^{-5}	6.3×10^{-6}
1.4×10^{-5}	8.8×10^{-6}
2.0×10^{-5}	1.2×10^{-5}
5.0×10^{-5}	2.6×10^{-5}
6.7×10^{-5}	3.1×10^{-5}

This reaction obeys Michaelis-Menten kinetics (*Case Study: Enzymes—Nature's Catalysts*, p. 540). Determine the value of $Rate_{max}$ for this reaction using the method described in Question 2 of that Case Study.

36. Insulin is a protein important in the metabolism of sugar. Its molar mass can be determined by means of an osmotic pressure experiment. A 50.0-mg sample of insulin was dissolved in enough water to make 100. mL of solution. This solution was determined to have an osmotic pressure of 21.8 mm H_2O. What is the molar mass of insulin? (Hint: The density of mercury is 13.6 g/mL.)

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

37. Which of the amino acids listed in Figure 24.2 is not chiral?

38. (a) What type of interaction holds DNA's double-helical strands together?

(b) Why would it not be good for DNA's double-helical strands to be held together by covalent bonds?

39. Do the DNA sequences ATGC and CGTA represent the same compound? Explain.

40. For many chemical reactions in the laboratory, a percent yield of the correct product of 95% is considered very good. Many biochemical reactions, however, require a much greater percent yield of the correct product.

(a) Assume that there is a process that replicates DNA with only 95% accuracy for each nucleotide added and that we wish to make complementary copies of identical strands of DNA 10 nucleotides long. What fraction of the molecules produced would have the correct sequence of nucleotides?

(b) Many naturally occurring DNA polymerases, enzymes that catalyze the replication of DNA, have an accuracy much greater, often being 99.999999% accurate. If an enzyme with this accuracy constructed a 10-nucleotide sequence of DNA, what fraction of the molecules would have the correct sequence?

41. (a) Describe what occurs in the process of transcription.
(b) Describe what occurs in the process of translation.

42. Which of the following statements is/are true?

(a) Breaking the P—O bond in ATP is an exothermic process.

(b) Making a new bond between the phosphorus atom in the phosphate group being cleaved off ATP and the OH group of water is an exothermic process.

(c) Breaking bonds is an endothermic process.

(d) The energy released in the hydrolysis of ATP may be used to run endothermic reactions in a cell.

25-9 Applications of Nuclear Chemistry

A PRIMORDIAL NUCLEAR REACTOR

The natural nuclear reactors in West Africa have been called "one of the greatest natural phenomena that ever occurred." In 1972, a French scientist noticed that the uranium taken from a mine in Oklo, Gabon, was strangely deficient in ^{235}U. Uranium exists in nature as two principal isotopes, ^{238}U (99.275% abundant) and ^{235}U (0.72% abundant). It is ^{235}U that most readily undergoes nuclear fission and is used to fuel nuclear power plants around the world. But the uranium found in the Oklo mines had an isotope ratio like that of the spent fuel that comes from modern reactors. Based on this and other evidence, scientists concluded that ^{235}U at the Oklo mine was once about 3% of the total and that a "natural" fission process occurred in the bed of uranium ore nearly 2 billion years ago.

But intriguing questions remained: Why could fission occur to a significant extent in this natural deposit of uranium and why didn't the "reactor" explode? Apparently,

Chapter Goals

See Chapter Goals Revisited (page 1006) for Study Questions keyed to these goals.

UNDERSTAND

- The criteria for nuclear stability and the processes by which unstable nuclides decay.
- The methods used to synthesize new isotopes of the elements.
- The plot showing numbers of protons and neutrons in stable and unstable nuclides.
- The graph showing binding energy per nucleon versus atomic number.
- Issues of safety and health with respect to radioactivity.
- Uses of radioactive isotopes in science and medicine.

DO

- Write equations for the decay of radioactive elements and the synthesis of new isotopes.
- Predict possible modes of decomposition of unstable nuclei based on n/p ratios.
- Calculate the binding energy and binding energy per nucleon for a particular isotope.
- Carry out calculations based on equations for the first-order rate of decomposition of unstable isotopes.

REMEMBER

- Nuclear decay series and their implications.
- Types of radiation.
- The processes of fission and fusion.

there must have been a moderator of neutron energy and a regulation mechanism. In a modern nuclear power reactor, control rods slow down the neutrons from nuclear fission so that they can induce fission in other ^{235}U nuclei; that is, they moderate the neutron energy. Without a moderator, the neutrons just fly off. In the Oklo reactors, water seeping into the bed of uranium ore could have acted as a moderator.

The reason the Oklo reactor did not explode is that water could have also been the regulator. As the fission process heated the water, it boiled off as steam. This caused the fission to stop, but it began again when more water seeped in. Scientists now believe this natural reactor would turn on for about 30 minutes and then shut down for several hours before turning on again. There is evidence this natural reactor functioned intermittently for about 1 million years, until the concentration of uranium isotopes was too low to keep the reaction going.

A Study Question related to this story is: 25.54.

History of science scholars cite areas of study out of which modern chemistry arose: technology, medicine, and alchemy. The third of these pillars, alchemy, was pursued in many cultures on three continents for well over 1000 years. Simply stated, the goal of the ancient alchemists was to turn less valuable materials into gold. We now recognize the futility of these efforts, because this goal is not reachable by chemical processes. But we now also know that their dream of transmuting one element into another can be achieved by means of nuclear reactions. This

Table 25.1 Characteristics of α, β, and γ Radiation

NAME	SYMBOLS	CHARGE	MASS (g/particle)
Alpha	^4_2He, $^4_2\alpha$	2+	6.65×10^{-24}
Beta	$^0_{-1}\text{e}$, $^0_{-1}\beta$	1−	9.11×10^{-28}
Gamma	γ	0	0

happens naturally in the decomposition of uranium and other radioactive elements, and scientists can intentionally carry out such reactions in the laboratory. The goal is no longer to make gold, however. Far more important and valuable products of nuclear reactions are possible.

Nuclear chemistry encompasses a wide range of topics that share one thing in common: they involve changes in the atom's nucleus. While nuclear "chemistry" is a major focus in this chapter, this subject cuts across many areas of science and modern society. Radioactive isotopes are used in medicine. Nuclear power provides a sizable fraction of energy for modern society. And then, there are nuclear weapons. . . .

25-1 Natural Radioactivity

Discovery of Radioactivity The discovery of radioactivity by Henri Becquerel and the isolation of radium and polonium from pitchblende, a uranium ore, by Marie Curie were described in *Key Experiments: How Do We Know the Nature of the Atom and Its Components,* Chapter 2.

In the late 19th century, while studying radiation emanating from uranium and thorium, Ernest Rutherford (1871–1937) stated, "There are present at least two distinct types of radiation—one that is readily absorbed, which will be termed for convenience ***α* (alpha) radiation**, and the other of a more penetrative character, which will be termed ***β* (beta) radiation**." Subsequently, charge-to-mass ratio measurements showed that α radiation is composed of helium nuclei (He^{2+}) and β radiation is composed of electrons (e^-) (Table 25.1).

Common Symbols: α and β Symbols used to represent alpha and beta particles do not include a plus or minus superscript, respectively, to show that they have a charge.

Rutherford hedged his bet when he said at least two types of radiation existed. A third type was later discovered by the French scientist Paul Villard (1860–1934); he named it ***γ* (gamma) radiation**, using the third letter in the Greek alphabet in keeping with Rutherford's scheme. Unlike α and β radiation, γ radiation is not affected by electric and magnetic fields. Rather, it is a form of electromagnetic radiation like x-rays but even more energetic.

Early studies measured the penetrating power of the three types of radiation (Figure 25.1). Alpha radiation is the least penetrating; it can be stopped by several sheets of ordinary paper or clothing. Beta particles can penetrate several millimeters of living bone or tissue, but about 0.5 cm of lead will stop the particles. Gamma radiation is the most penetrating. Thick layers of lead or concrete are required to

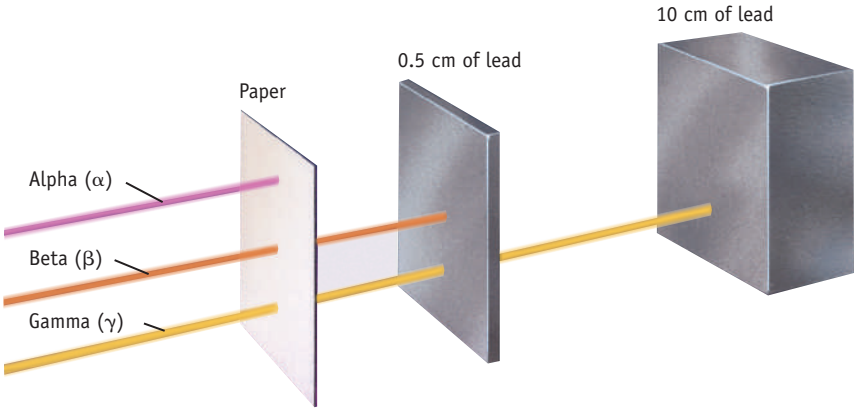

FIGURE 25.1 The relative penetrating ability of α, β, and γ radiation. Highly charged α particles interact strongly with matter and are stopped by a piece of paper. Beta particles, with less mass and a lower charge, interact to a lesser extent with matter and thus can penetrate farther. Gamma radiation is the most penetrating.

shield the body from this radiation, and γ rays can pass completely through the human body.

Alpha and β particles typically possess high kinetic energies. The energy of γ radiation is similarly very high. When α and β particles are stopped by a material, or when γ radiation is absorbed, the energy associated with the radiation is transferred to the material. This fact is important because the damage caused by radiation is related to the energy absorbed (▶ Section 25-8).

25-2 Nuclear Reactions and Radioactive Decay

Equations for Nuclear Reactions

In 1903, Rutherford and Frederick Soddy (1877–1956) proposed that radioactivity is the result of a natural change of an isotope of one element into an isotope of a different element. Such processes are called **nuclear reactions**.

Consider a reaction in which radium-226 (the isotope of radium with mass number 226) emits an α particle to form radon-222. The equation for this reaction is

$$^{226}_{88}\text{Ra} \longrightarrow {}^{4}_{2}\alpha + {}^{222}_{86}\text{Rn}$$

Symbols Used in Nuclear Equations The mass number is included as a superscript, and the atomic number is included as a subscript preceding the symbols for reactants and products. This is done to facilitate balancing these equations.

In a nuclear reaction, the sum of the mass numbers of reacting particles must equal the sum of the mass numbers of products. Furthermore, to maintain nuclear charge balance, the sum of the atomic numbers of the products must equal the sum of the atomic numbers of the reactants. These principles are illustrated using the preceding nuclear equation:

	$^{226}_{88}$Ra RADIUM-226	$\longrightarrow$ $\longrightarrow$	$^{4}_{2}\alpha$ α PARTICLE	+ +	$^{222}_{86}$Rn RADON-222
Mass number: (protons + neutrons)	226	=	4	+	222
Atomic number: (protons)	88	=	2	+	86

Alpha-particle emission causes a decrease of two units in atomic number and four units in the mass number.

Similarly, nuclear mass and nuclear charge balance accompany β-particle emission, as illustrated by the decomposition of uranium-239:

	$^{239}_{92}$U URANIUM-239	$\longrightarrow$ $\longrightarrow$	$^{0}_{-1}\beta$ β PARTICLE	+ +	$^{239}_{93}$Np NEPTUNIUM-239
Mass number: (protons + neutrons)	239	=	0	+	239
Atomic number: (protons)	92	=	−1	+	93

The β particle has a charge of $1-$. Charge balance requires that the atomic number of the product be one unit greater than the atomic number of the reacting nucleus. The mass number does not change in this process.

How does a nucleus, composed of protons and neutrons, eject an electron? It is a complex process, but the net result is the conversion within the nucleus of a neutron to a proton and an electron.

$$\underset{\text{neutron}}{{}^{1}_{0}\text{n}} \longrightarrow \underset{\text{electron}}{{}^{0}_{-1}\text{e}} + \underset{\text{proton}}{{}^{1}_{1}\text{p}}$$

Notice that the mass and charge numbers balance in this equation.

What is the origin of the γ radiation that accompanies many nuclear reactions? Recall that a photon of visible light is emitted when an atom undergoes a transition from an excited electronic state to a lower energy state (◀ Section 6-3). Gamma radiation originates from transitions between nuclear energy levels. Nuclear reactions often

result in the formation of a product nucleus in an excited nuclear state. One option is to return to the ground state by emitting a photon. The energy of γ radiation is a measure of the large energy difference between the energy levels in the nucleus.

Radioactive Decay Series

Several naturally occurring radioactive isotopes decay to form a product that is also radioactive. When this happens, the initial nuclear reaction is followed by a second nuclear reaction; if the situation is repeated, a third and a fourth nuclear reaction occur; and so on. Eventually, a nonradioactive isotope is formed to end the series. Such a sequence of nuclear reactions is called a **radioactive decay series**. In each step of this sequence, the reactant nucleus is called the *parent,* and the product is called the *daughter*.

Uranium-238, the most abundant of three naturally occurring uranium isotopes, heads one of four radioactive decay series. This series begins with the loss of an α particle from $^{238}_{92}$U to form radioactive $^{234}_{90}$Th. Thorium-234 then decomposes by β emission to $^{234}_{91}$Pa, which emits a β particle to give $^{234}_{92}$U. Uranium-234 is an α emitter, forming $^{230}_{90}$Th. Further α and β emissions follow, until the series ends with formation of the stable, nonradioactive isotope, $^{206}_{82}$Pb. In all, this radioactive decay series converting $^{238}_{92}$U to $^{206}_{82}$Pb is made up of 14 decays, with eight α and six β particles being emitted. The series is portrayed graphically by plotting atomic number versus mass number (Figure 25.2). An equation can be written for each step in the sequence. Equations for the first four steps in the uranium-238 radioactive decay series are as follows:

Step 1. $^{238}_{92}\text{U} \longrightarrow {}^{234}_{90}\text{Th} + {}^{4}_{2}\alpha$

Step 2. $^{234}_{90}\text{Th} \longrightarrow {}^{234}_{91}\text{Pa} + {}^{0}_{-1}\beta$

Step 3. $^{234}_{91}\text{Pa} \longrightarrow {}^{234}_{92}\text{U} + {}^{0}_{-1}\beta$

Step 4. $^{234}_{92}\text{U} \longrightarrow {}^{230}_{90}\text{Th} + {}^{4}_{2}\alpha$

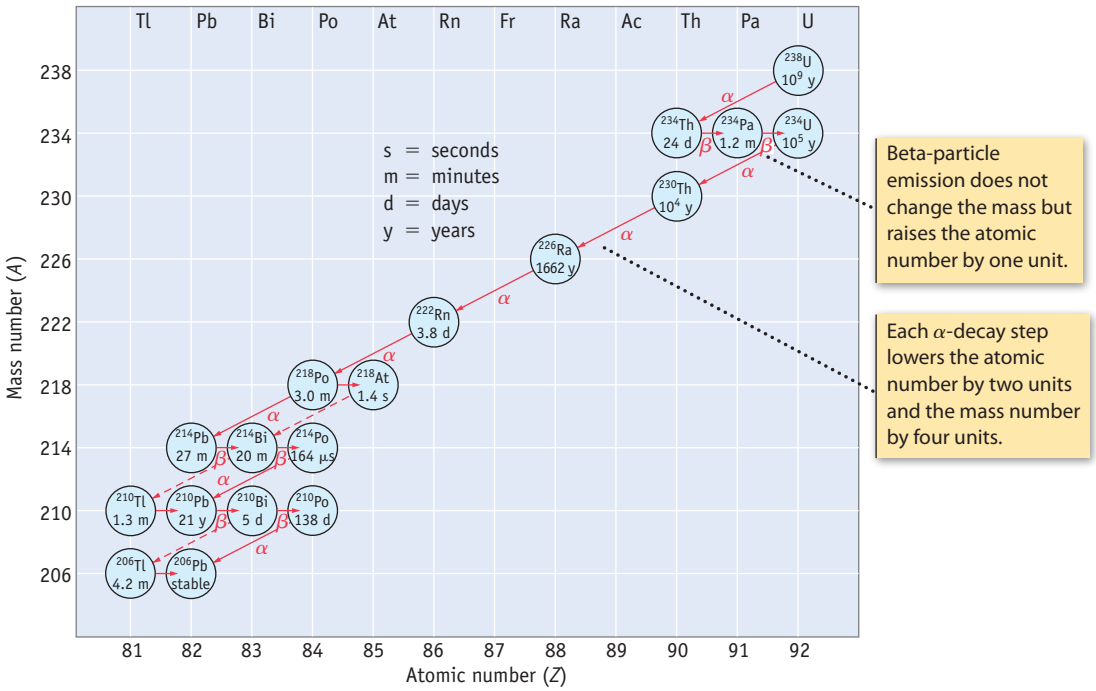

FIGURE 25.2 The uranium-238 radioactive decay series. The steps in this radioactive decay series are shown graphically in this plot of mass number versus atomic number. Half-lives of the isotopes are included on the chart. Notice that several of the isotopes in this series decompose by two different pathways.

Uranium ore contains trace quantities of the radioactive elements formed in the radioactive decay series. A significant development in nuclear chemistry was Marie Curie's discovery in 1898 of radium and polonium as trace components of pitchblende, a uranium ore. The amount of each of these elements is small because their isotopes have short half-lives. Consequently, Marie Curie was able to isolate only a single gram of radium from 7 tons of ore. It is a credit to her skills as a chemist that she extracted sufficient amounts of radium and polonium from uranium ore to identify these elements.

The uranium-238 radioactive decay series is also the source of the environmental hazard radon. Trace quantities of uranium are often present naturally in soil and rocks, and radon-222 is being continuously formed. Because radon is chemically inert, it is not trapped by chemical processes in soil or water and is free to seep into mines or into homes through pores in cement block walls, through cracks in the basement floor or walls, or around pipes. Because it is more dense than air, radon tends to collect in low spots, and its concentration can build up in a basement if steps are not taken to remove it.

The major health hazard from radon, when it is inhaled by humans, arises not from radon itself but from its decomposition product, polonium.

$$^{222}_{86}\text{Rn} \longrightarrow {}^{218}_{84}\text{Po} + {}^{4}_{2}\alpha \qquad t_{1/2} = 3.82 \text{ days}$$

$$^{218}_{84}\text{Po} \longrightarrow {}^{214}_{82}\text{Pb} + {}^{4}_{2}\alpha \qquad t_{1/2} = 3.04 \text{ minutes}$$

Radon does not undergo chemical reactions or form compounds that can be taken up in the body. Polonium, however, is not chemically inert. Polonium-218 can lodge in body tissues, where it undergoes α decay to give lead-214, another radioactive isotope. The range of an α particle in body tissue is quite small, perhaps 0.7 mm. This is approximately the thickness of the epithelial cells of the lungs, however, so α-particle radiation can cause serious damage to lung tissues.

Virtually every home in the United States has some level of radon, and kits can be purchased to test for the presence of this gas. If a significant amount of radon gas is detected in your home, you should take corrective actions such as sealing cracks around the foundation and in the basement. It may be reassuring to know that the health risks associated with radon are low. The likelihood of getting lung cancer from exposure to radon is about the same as the likelihood of dying in an accident in your home.

© Cengage Learning/Charles D. Winters

Radon detector. This kit is intended for use in the home to detect radon gas. The small device is placed in the home's basement for a given time period and is then sent to a laboratory to measure the amount of radon that might be present.

EXAMPLE 25.1

Radioactive Decay Series

Problem Another radioactive decay series begins with $^{235}_{92}\text{U}$ and ends with $^{207}_{82}\text{Pb}$.

(a) How many α and β particles are emitted in this series?

(b) The first three steps of this series are (in order) α, β, and α emission. Write an equation for each of these steps.

What Do You Know? You are given the starting (long-lived radioactive) isotope and the final (stable) isotope. A series of α and β reactions is the link between these two species.

Strategy First, find the total change in atomic number and mass number. A combination of α and β particles is required that will decrease the total nuclear mass by 28 (235 − 207) and at the same time decrease the atomic number by 10 (92 − 82). Each equation must give symbols for the parent and daughter nuclei and the emitted particle. In the equations, the sums of the atomic numbers and mass numbers for reactants and products must be equal.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Solution

(a) Mass declines by 28 mass units (235 − 207). Because a decrease of 4 mass units occurs with each α emission, 7 α particles must be emitted. Also, for each α emission, the atomic number decreases by 2. Emission of 7 α particles would cause the atomic number to decrease by 14, but the actual decrease in atomic number is 10 (92 − 82). This means that 4 β particles must also have been emitted because each β emission increases the atomic number of the product by one unit. Thus, the radioactive decay sequence involves emission of 7 α and 4 β particles.

(b) Step 1. $^{235}_{92}\text{U} \rightarrow {}^{231}_{90}\text{Th} + {}^{4}_{2}\alpha$

Step 2. $^{231}_{90}\text{Th} \rightarrow {}^{231}_{91}\text{Pa} + {}^{0}_{-1}\beta$

Step 3. $^{231}_{91}\text{Pa} \rightarrow {}^{227}_{89}\text{Ac} + {}^{4}_{2}\alpha$

Think about Your Answer Because the mass number changes in these series only when an α particle is lost, all of the mass numbers in a given decay series are some multiple of four less than the first isotope in the series. For the series beginning with U-238, the mass numbers are in the series 238, 234, 230, . . . , 206. This series is sometimes called the $4n + 2$ *series* because each mass number (M) fits the equation $4n + 2 = M$, where n is an integer (n is 59 for the first member of this series and 51 for the last member). For the series headed by $^{235}_{92}$U, the mass numbers are 235, 231, 227, . . . , 207; this is the $4n + 3$ *series*.

Two other decay series are possible. One, called the $4n$ *series* and beginning with ^{232}Th, is found in nature. The other, the $4n + 1$ series, is not found because no member of the series has a very long half-life. During the 4.5 billion years since this planet was formed, all radioactive members of the $4n + 1$ series have completely decayed to the end product, ^{209}Bi.

Check Your Understanding

(a) Six α and four β particles are emitted in the thorium-232 radioactive decay series before a stable isotope is reached. What is the final product in this series?

(b) The first three steps in the thorium-232 decay series (in order) are α, β, and β emission. Write an equation for each step.

Other Types of Radioactive Decay

Most naturally occurring radioactive elements decay by emission of α, β, and γ radiation. Other nuclear decay processes became known, however, when new radioactive elements were synthesized by artificial means. These include **positron** ($_{+1}^{0}\boldsymbol{\beta}$) **emission** and **electron capture**.

Positrons Positrons were discovered by Carl Anderson (1905–1991) in 1932. The positron is one of a group of particles known as *antimatter*. If matter and antimatter particles collide, mutual annihilation occurs, with energy being emitted.

Positrons ($_{+1}^{0}\beta$) and electrons have the same mass but opposite charge. The positron is the antimatter analog to an electron. *Positron emission* by polonium-207, for example, results in the formation of bismuth-207.

	$^{207}_{84}$**Po** **POLONIUM-207**	→ →	$^{0}_{+1}\boldsymbol{\beta}$ **POSITRON**	+ +	$^{207}_{83}$**Bi** **BISMUTH-207**
Mass number: (protons + neutrons)	207	=	0	+	207
Atomic number: (protons)	84	=	1	+	83

To retain charge balance, *positron decay results in a decrease in the atomic number.*

In *electron capture*, an extranuclear electron is captured by the nucleus. The mass number is unchanged, and *the atomic number is reduced by 1*. (In an old nomenclature, the innermost electron shell was called the *K shell*, and electron capture was called *K capture*.)

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

	$^{7}_{4}$Be BERYLLIUM-7	+ +	$^{0}_{-1}e$ ELECTRON	→ →	$^{7}_{3}$Li LITHIUM-7
Mass number: (protons + neutrons)	7	+	0	=	7
Atomic number: (protons)	4	+	−1	=	3

In summary, most unstable nuclei decay by one of four paths: α or β decay, positron emission, or electron capture. Gamma radiation often accompanies these processes. Section 25-6 introduces a fifth way that nuclei decompose, *fission*.

Neutrinos and Antineutrinos
Beta particles having a wide range of energies are emitted. To balance the energy and momentum associated with β decay, it is necessary to postulate the concurrent emission of another particle, the *antineutrino*. Similarly, neutrino emission accompanies positron emission. Much study has gone into detecting neutrinos and antineutrinos. These particles do not have a charge. They are believed to have mass, but their mass is so small it has not been possible to measure it. Neutrinos and antineutrinos are not included when writing nuclear equations.

EXAMPLE 25.2

Nuclear Reactions

Problem Complete the following equations. Give the symbol, mass number, and atomic number of the product species.

(a) $^{37}_{18}\text{Ar} + {}^{0}_{-1}\text{e} \longrightarrow ?$

(b) $^{11}_{6}\text{C} \longrightarrow {}^{11}_{5}\text{B} + ?$

(c) $^{35}_{16}\text{S} \longrightarrow {}^{35}_{17}\text{Cl} + ?$

(d) $^{30}_{15}\text{P} \longrightarrow {}^{0}_{+1}\beta + ?$

What Do You Know? You are given the reactant and one of two products formed in these nuclear reactions. You know that both the masses and charges must balance in a balanced nuclear equation.

Strategy The missing product in each reaction can be determined by recognizing that the sums of mass numbers and atomic numbers for products and reactants must be equal. When you know the nuclear mass and nuclear charge of the product, you can identify it with the appropriate symbol.

Solution

(a) This is an electron capture reaction. The product has a mass number of 37 + 0 = 37 and an atomic number of 18 − 1 = 17. Therefore, the symbol for the product is $^{37}_{17}\text{Cl}$.

(b) This missing particle has a mass of zero and a charge of 1+; these are the characteristics of a positron, $^{0}_{+1}\beta$. If this particle is included in the equation, the sums of the atomic numbers (6 = 5 + 1) and the mass numbers (11) on both sides of the equation are equal.

(c) A β particle, $^{0}_{-1}\beta$, is required to balance the mass numbers (35) and atomic numbers (16 = 17 − 1) in the equation.

(d) The product nucleus has mass number 30 and atomic number 14. This identifies the unknown as $^{30}_{14}\text{Si}$.

Think about Your Answer The product in each reaction is a stable isotope. As discussed in the next section, there is a narrow range of neutron-to-proton ratios for stable isotopes. Spontaneous nuclear reactions always occur in a way that moves either into or closer to the narrow range of stable isotopes.

Check Your Understanding

Indicate the symbol, the mass number, and the atomic number of the missing product in each of the following nuclear reactions.

(a) $^{13}_{7}\text{N} \longrightarrow {}^{13}_{6}\text{C} + ?$

(b) $^{41}_{20}\text{Ca} + {}^{0}_{-1}\text{e} \longrightarrow ?$

(c) $^{90}_{38}\text{Sr} \longrightarrow {}^{90}_{39}\text{Y} + ?$

(d) $^{22}_{11}\text{Na} \longrightarrow ? + {}^{0}_{+1}\beta$

REVIEW & CHECK FOR SECTION 25-2

1. Identify the type of radiation associated with a nuclear reaction converting radon-222 to polonium-218.

   (a) alpha radiation
   (b) beta radiation
   (c) positron emission
   (d) fission

2. The uranium-235 radioactive decay series ends with the formation of ^{207}Pb. How many alpha (α) and beta (β) particles are emitted in this series?

   (a) 8 α and 4 β
   (b) 7 α and 4 β
   (c) 7 α and 6 β
   (d) 6 α and 4 β

3. Which of the following reactions involves emission of a beta particle?

   (a) $^{13}_{7}N \rightarrow {}^{13}_{6}C + ?$
   (b) $^{41}_{20}Ca + {}^{0}_{-1}e \rightarrow ?$
   (c) $^{90}_{38}Sr \rightarrow {}^{90}_{39}Y + ?$
   (d) $^{232}_{90}Th \rightarrow {}^{228}_{88}Ra + ?$

25-3 Stability of Atomic Nuclei

We can learn something about nuclear stability from Figure 25.3, a plot of the composition of the known isotopes of the elements. The horizontal axis represents the number of protons, and the vertical axis gives the number of neutrons. Each circle represents an isotope identified by the number of neutrons and protons contained in its nucleus. The black circles represent stable (nonradioactive) isotopes, 254 in number, and the red circles represent some of the known radioactive isotopes. For example, the three isotopes of hydrogen are $^{1}_{1}H$ and $^{2}_{1}H$ (neither is radioactive) and

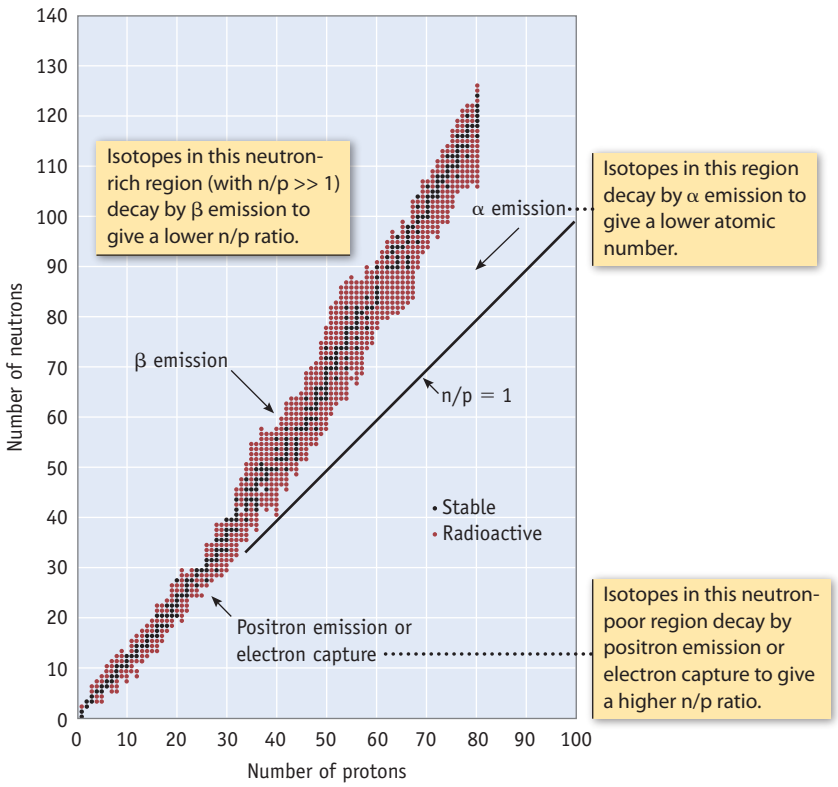

FIGURE 25.3 Stable and unstable isotopes. A graph of the number of neutrons (n) versus the number of protons (p) for stable (*black circles*) and radioactive (*red circles*) isotopes from hydrogen to bismuth. This graph is used to assess criteria for nuclear stability and to predict modes of decay for unstable nuclei.

$^{3}_{1}H$ (tritium, radioactive). For lithium, the third element, isotopes are known with mass numbers 4, 5, 6, and 7. The isotopes with masses of 6 and 7 (shown in black) are stable, whereas the other two isotopes (in red) are radioactive.

Figure 25.3 gives us the following information about nuclear stability:

- Stable isotopes fall in a very narrow range called the **band of stability**. It is remarkable how few isotopes are stable.
- Only two stable isotopes ($^{1}_{1}H$ and $^{3}_{2}He$) have more protons than neutrons.
- Up to calcium ($Z = 20$), stable isotopes often have equal numbers of protons and neutrons or only one or two more neutrons than protons.
- Beyond calcium, the neutron-to-proton ratio is always greater than 1. As the mass increases, the band of stable isotopes deviates more and more from a 1:1 neutron-to-proton ratio (the line in Figure 25.3 for which n/p = 1).
- Beyond bismuth (83 protons and 126 neutrons), all isotopes are unstable and radioactive. There is apparently no nuclear "superglue" strong enough to hold heavy nuclei together.
- Isotopes that fall farther from the band of stability tend to have shorter half-lives than do unstable isotopes nearer to the band of stability.
- Isotope stability is associated with even atomic numbers and even atomic weights. Among the stable isotopes, 148 have an even number of protons and neutrons, 53 have an even number of protons and an odd number of neutrons, and 48 have an odd number of protons and an even number of neutrons. Only five stable isotopes ($^{2}_{1}H$, $^{6}_{3}Li$, $^{10}_{5}B$, $^{14}_{7}N$, and $^{180}_{73}Ta$) have odd numbers of both protons and neutrons.

The Band of Stability and Radioactive Decay

Besides being a criterion for stability, the neutron-to-proton ratio can assist in predicting what type of radioactive decay will be observed. Unstable nuclei decay in a manner that brings them toward a stable neutron-to-proton ratio—that is, toward the band of stability.

- All elements beyond bismuth ($Z = 83$) are unstable. For an element beyond this atomic number, a process that decreases the atomic number is needed to reach the band of stability. Alpha emission is an effective way to do this because each emission decreases the atomic number by 2. For example, americium, the radioactive element used in smoke detectors, decays by α emission:

$$^{243}_{95}Am \rightarrow {}^{4}_{2}\alpha + {}^{239}_{93}Np$$

- Beta emission occurs for isotopes that have a high neutron-to-proton ratio—that is, isotopes above the band of stability. With β decay, the atomic number increases by 1, and the mass number remains constant, resulting in a lower neutron-to-proton ratio:

$$^{60}_{27}Co \rightarrow {}^{0}_{-1}\beta + {}^{60}_{28}Ni$$

- Isotopes with a low neutron-to-proton ratio, below the band of stability, decay by positron emission or by electron capture. Both processes lead to product nuclei with a lower atomic number and the same mass number and move the product closer to the band of stability:

$$^{13}_{7}N \rightarrow {}^{0}_{+1}\beta + {}^{13}_{6}C$$

$$^{41}_{20}Ca + {}^{0}_{-1}e \rightarrow {}^{41}_{19}K$$

EXAMPLE 25.3

Predicting Modes of Radioactive Decay

Problem Identify probable mode(s) of decay for each isotope and write an equation for the decay process.

(a) oxygen-15, $^{15}_{8}O$

(b) uranium-234, $^{234}_{92}U$

(c) fluorine-20, $^{20}_{9}F$

(d) manganese-56, $^{56}_{25}Mn$

What Do You Know? You are given the formulas for four radioactive isotopes. The possible modes of decomposition are α, β, or positron emission and electron capture. The preferred mode will give a more stable isotope and create a nucleus that is closer to the band of stability.

Strategy There are two main ideas to look at. First, if Z is greater than 83, then α decay is likely. Second, consider the n/p ratio. If the ratio is much greater than 1, then β decay is probable. If the ratio is less than 1, then positron emission or electron capture is the more likely process. It is not possible to choose between the latter two modes of decay without further information.

Solution

(a) Oxygen-15 has 7 neutrons and 8 protons, so the neutron-to-proton (n/p) ratio is less than 1—too low for ^{15}O to be stable. Nuclei with too few neutrons are expected to decay by either positron emission or electron capture. In this instance, the process is $^{0}_{+1}\beta$ emission, and the equation is $^{15}_{8}O \rightarrow {}^{0}_{+1}\beta + {}^{15}_{7}N$.

(b) Alpha emission is a common mode of decay for isotopes of elements with atomic numbers higher than 83. The decay of uranium-234 is one example:

$$^{234}_{92}U \rightarrow {}^{230}_{90}Th + {}^{4}_{2}\alpha$$

(c) Fluorine-20 has 11 neutrons and 9 protons, a high n/p ratio. The ratio is lowered by β emission:

$$^{20}_{9}F \rightarrow {}^{0}_{-1}\beta + {}^{20}_{10}Ne$$

(d) The mass number of ^{56}Mn is higher than the atomic weight of the element (54.85). This suggests that this radioactive isotope has an excess of neutrons (giving a high n/p ratio), in which case it would be expected to decay by β emission:

$$^{56}_{25}Mn \rightarrow {}^{0}_{-1}\beta + {}^{56}_{26}Fe$$

Think about Your Answer Decomposition can occur by four possible paths, α and β emission, positron emission, and electron capture. Whether the decay follows beta emission or positron emission (or electron capture) is predicted by the neutron/proton ratio, relative to the n/p ratio in stable isotopes.

Check Your Understanding

Write an equation for the probable mode of decay for each of the following unstable isotopes, and write an equation for that nuclear reaction.

(a) silicon-32, $^{32}_{14}Si$

(b) titanium-45, $^{45}_{22}Ti$

(c) plutonium-239, $^{239}_{94}Pu$

(d) potassium-42, $^{42}_{19}K$

Nuclear Binding Energy

An atomic nucleus can contain as many as 83 protons and still be stable. For stability, nuclear binding (attractive) forces must be greater than the electrostatic repulsive forces between the closely packed protons in the nucleus. **Nuclear binding energy**,

E_b, is defined as the energy required to separate the nucleus of an atom into protons and neutrons. For example, the nuclear binding energy for deuterium is the energy required to convert one mole of deuterium (^2_1H) nuclei into one mole of protons and one mole of neutrons.

$$^2_1H \rightarrow {}^1_1p + {}^1_0n \qquad E_b = +2.15 \times 10^8 \text{ kJ/mol}$$

The positive sign for E_b indicates that energy is required for this process. A deuterium nucleus is more stable than an isolated proton and an isolated neutron, just as the H_2 molecule is more stable than two isolated H atoms. Recall, however, that the H—H bond energy is only 436 kJ/mol. The energy holding a proton and a neutron together in a deuterium nucleus, 2.15×10^8 kJ/mol, is about 500,000 times larger than the typical covalent bond energies.

To further understand nuclear binding energy, we turn to an experimental observation and a theory. The experimental observation is that the mass of a nucleus is *always* less than the sum of the masses of its constituent protons and neutrons. The theory is that the "missing mass," called the **mass defect**, is equated with the energy that holds the nuclear particles together.

The mass defect for deuterium is the difference between the mass of a deuterium nucleus and the sum of the masses of a proton and a neutron. Mass spectrometric measurements (◀ Section 2-3) give the masses of these particles to a high level of accuracy, providing the numbers needed to carry out calculations of mass defects.

Masses of atomic nuclei are not generally listed in reference tables, but masses of atoms are. Calculation of the mass defect can be carried out using masses of atoms instead of masses of nuclei. By using atomic masses, we are including in this calculation the masses of extranuclear electrons in the reactants and the products. However, because the same number of extranuclear electrons appears in products and reactants, this does not affect the result. Thus, for one mole of deuterium nuclei, the mass defect is found as follows:

$$\begin{array}{ccccc} ^2_1H & \rightarrow & ^1_1H & + & ^1_0n \\ 2.01410 \text{ g/mol} & & 1.007825 \text{ g/mol} & & 1.008665 \text{ g/mol} \end{array}$$

$$\begin{aligned} \text{Mass defect} = \Delta m &= \text{mass of products} - \text{mass of reactants} \\ &= [1.007825 \text{ g/mol} + 1.008665 \text{ g/mol}] - 2.01410 \text{ g/mol} \\ &= 0.00239 \text{ g/mol} \end{aligned}$$

The relationship between mass and energy is contained in Albert Einstein's 1905 theory of special relativity, which holds that mass and energy are different manifestations of the same quantity. Einstein defined the energy–mass relationship: Energy is equivalent to mass times the square of the speed of light; that is, $E = mc^2$. In the case of atomic nuclei, it is assumed that the missing mass (the mass defect, Δm) is equated with the binding energy holding the nucleus together.

$$E_b = (\Delta m)c^2 \qquad \textbf{(25.1)}$$

If Δm is given in kilograms and the speed of light is given in meters per second, E_b will have units of joules (because 1 J = 1 kg · m^2/s^2). For the decomposition of one mole of deuterium nuclei to one mole of protons and one mole of neutrons, we have

$$\begin{aligned} E_b &= (2.39 \times 10^{-6} \text{ kg/mol})(2.998 \times 10^8 \text{ m/s})^2 \\ &= 2.15 \times 10^{11} \text{ J/mol of } ^2_1H \text{ nuclei } (= 2.15 \times 10^8 \text{ kJ/mol of } ^2_1H \text{ nuclei}) \end{aligned}$$

The nuclear stabilities of different elements are compared using the **binding energy per mole of nucleons**. (**Nucleon** is the general name given to nuclear particles—that is, protons and neutrons.) A deuterium nucleus contains two

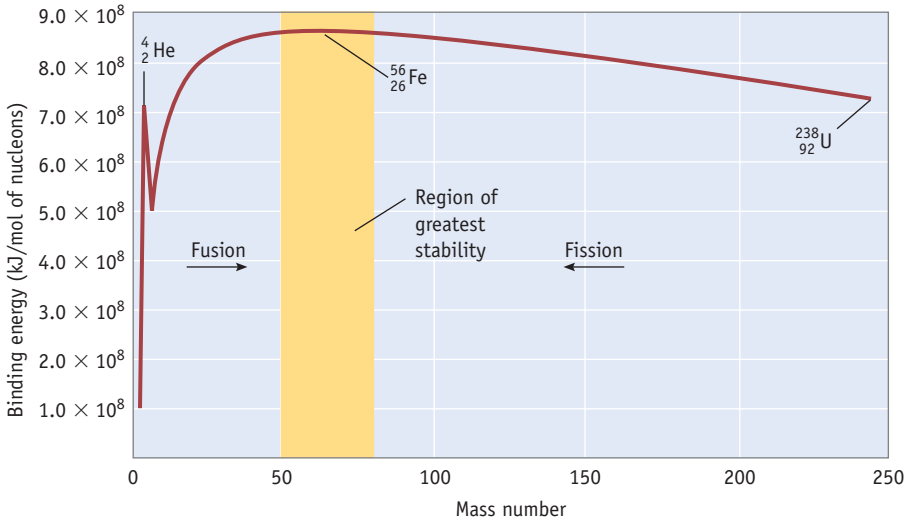

FIGURE 25.4 Relative stability of nuclei. Binding energy per nucleon for the most stable isotope of elements between hydrogen and uranium is plotted as a function of mass number. (Fission and fusion are discussed in Sections 25-6 and 25-7.)

nucleons, so the binding energy per mole of nucleons, E_b/n, is 2.15×10^8 kJ/mol divided by 2, or 1.08×10^8 kJ/mol nucleon.

$$E_b/n = \left(\frac{2.15 \times 10^8 \text{ kJ}}{\text{mol } {}^2_1\text{H nuclei}}\right)\left(\frac{1 \text{ mol } {}^2_1\text{H nuclei}}{2 \text{ mol nucleons}}\right)$$

$$E_b/n = 1.08 \times 10^8 \text{ kJ/mol nucleons}$$

The binding energy per nucleon can be calculated for any atom whose mass is known. Then, to compare nuclear stabilities, we can plot binding energies per nucleon as a function of mass number (Figure 25.4). The greater the binding energy per nucleon, the greater the stability of the nucleus. From the graph in Figure 25.4, the point of maximum nuclear stability occurs at a mass of 56 (that is, at iron in the periodic table).

EXAMPLE 25.4

Nuclear Binding Energy

Problem Calculate the binding energy per mole of nucleons, E_b (in kJ/mol), and the binding energy per nucleon, E_b/n (in kJ/mol nucleon), for carbon-12.

What Do You Know? The mass of carbon-12 is, by definition, exactly 12 g/mol. You will need the molar masses of hydrogen atoms ($^1_1$H) and neutrons (1.007825 g/mol and 1.008665 g/mol, respectively, to determine the mass defect.

Strategy The mass defect is the difference between the mass of carbon-12 and the masses of 6 protons, 6 neutrons, and 6 electrons. The mass of 1 mol of protons and 1 mol of electrons can be taken into account by using the molar mass of $^1_1$H. Use the values given to calculate the mass defect (in g/mol). The binding energy is calculated from the mass defect using Equation 25.1.

Solution The mass of $^1_1$H is 1.007825 g/mol, and the mass of $^1_0$n is 1.008665 g/mol. Carbon-12, $^{12}_6$C, is the standard for the atomic masses in the periodic table, and its mass is defined as exactly 12 g/mol

$$\Delta m = [(6 \times \text{mass } {}^1_1\text{H}) + (6 \times \text{mass } {}^1_0\text{n})] - \text{mass } {}^{12}_6\text{C}$$

$$= [(6 \times 1.007825 \text{ g/mol}) + (6 \times 1.008665 \text{ g/mol})] - 12.000000 \text{ g/mol}$$

$$= 9.8940 \times 10^{-2} \text{ g/mol}$$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The binding energy is calculated using Equation 25.1. Using the mass in kilograms and the speed of light in meters per second gives the binding energy in joules:

$$E_b = (\Delta m)c^2$$
$$= (9.8940 \times 10^{-5}\ \text{kg/mol})(2.99792 \times 10^8\ \text{m/s})^2$$
$$= 8.8923 \times 10^{12}\ \text{J/mol}\ (= 8.8923 \times 10^9\ \text{kJ/mol})$$

The binding energy per nucleon, E_b/n, is determined by dividing the binding energy by 12 (the number of nucleons).

$$\frac{E_b}{n} = \frac{8.8923 \times 10^9\ \text{kJ/mol}}{12\ \text{mol nucleons/mol}}$$
$$= 7.4102 \times 10^8\ \text{kJ/mol nucleons}$$

Think about Your Answer The binding energy is a very large quantity of energy compared to those of ordinary chemical reactions. Compare binding energy to the very exothermic reaction of hydrogen and oxygen to form water vapor, for which $\Delta_r H°$ is only −242 kJ per mol of water vapor formed at 25 °C.

Check Your Understanding

Calculate the binding energy per nucleon, in kilojoules per mole, for lithium-6. The molar mass of $^6_3$Li is 6.015125 g/mol.

REVIEW & CHECK FOR SECTION 25-3

1. Among the listed species, which has the highest binding energy per nucleon?

   (a) $^2_1$D (b) $^{20}_{10}$Ne (c) $^{56}_{26}$Fe (d) $^{238}_{92}$U

25-4 Rates of Nuclear Decay

Half-Life

When a new radioactive isotope is identified, its *half-life* is usually determined. Half-life ($t_{1/2}$) is used in nuclear chemistry in the same way it is used when discussing the kinetics of first-order chemical reactions (◀ Section 14-4): It is the time required for half of a sample to decay to products (Figure 25.5). Recall that for first-order kinetics the half-life is independent of the amount of sample.

Half-lives for radioactive isotopes cover a wide range of values. Uranium-238 has one of the longer half-lives, 4.47×10^9 years, a length of time close to the age of

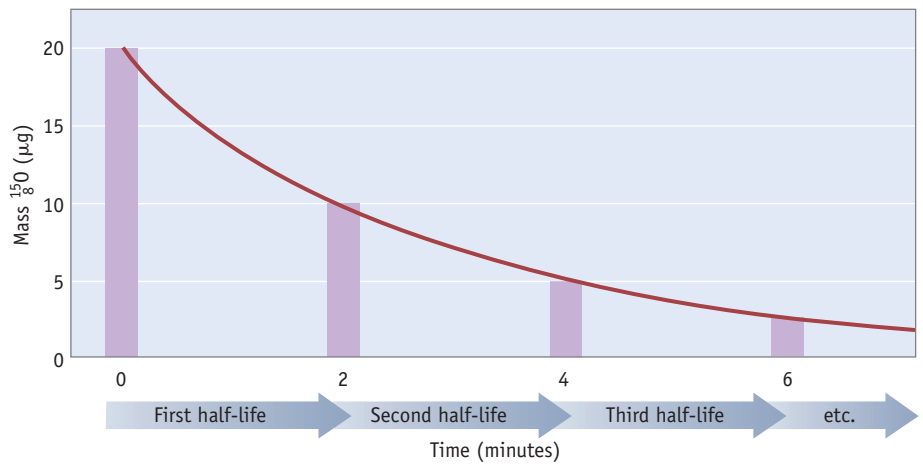

FIGURE 25.5 Decay of 20.0 μg of oxygen-15. After each half-life period of 2.0 minutes, the mass of oxygen-15 decreases by one half. (Oxygen-15 decays by positron emission.)

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the Earth (estimated at 4.5–4.6 $\times$ 10^9 years). Thus, roughly half of the uranium-238 present when the planet was formed is still around. At the other end of the range of half-lives are isotopes such as the 277 isotope of element 112 (recently named copernicium, ^{277}Cn), which has a half-life of 240 microseconds (1 μs = 1 $\times$ 10^{-6} s).

Half-life provides an easy way to estimate the time required before a radioactive element is no longer a health hazard. Strontium-90, for example, is a β emitter with a half-life of 29.1 years. Significant quantities of strontium-90 were dispersed into the environment during atmospheric nuclear bomb tests in the 1950s and 1960s, and, from the half-life, we know that about one-fourth is still around. The health problems associated with strontium-90 arise because calcium and strontium have similar chemical properties. Strontium-90 is taken into the body and deposited in bone, taking the place of calcium. Radiation damage by strontium-90 (a β emitter) in bone has been directly linked to bone-related cancers.

EXAMPLE 25.5

Using Half-Life

Problem Radioactive iodine-131, used to treat hyperthyroidism, has a half-life of 8.04 days.

(a) If you have 8.8 μg (micrograms) of this isotope, what mass remains after 32.2 days?

(b) How long will it take for a sample of iodine-131 to decay to one eighth of its activity?

(c) Estimate the length of time necessary for the sample to decay to 10% of its original activity.

What Do You Know? The half-life of ^{131}I, 8.04 days, is given in the problem.

Strategy This problem asks you to use half-life to qualitatively assess the rate of decay. After one half-life, half of the sample remains. After another half-life, the amount of sample is again decreased by half to one fourth of its original value. To answer these questions, assess the number of half-lives that have elapsed and use this information to determine the amount of sample remaining.

Solution

(a) The time elapsed, 32.2 days, is 4 half-lives (32.2/8.04 = 4). The amount of iodine-131 has decreased to 1/16 of the original amount [1/2 $\times$ 1/2 $\times$ 1/2 $\times$ 1/2 = $(1/2)^4$ = 1/16]. The amount of iodine remaining is 8.8 μg $\times$ $(1/2)^4$ or 0.55 μg.

(b) After 3 half-lives (24.12 days), the amount of iodine-131 remaining is 1/8 [= $(1/2)^3$] of the original amount. The amount remaining is 8.8 μg $\times$ $(1/2)^3$ = 1.1 μg.

(c) After 3 half-lives, 1/8 (12.5%) of the sample remains; after 4 half-lives, 1/16 (6.25%) remains. It will take between 3 and 4 half-lives, between 24.12 and 32.2 days, to decrease the amount of sample to 10% of its original value.

Think about Your Answer You will find it useful to make approximations as we have done in (c). An exact time can be calculated from the first-order rate law (Equation 25.5).

Check Your Understanding

Tritium ($^3_1$H), a radioactive isotope of hydrogen, has a half-life of 12.3 years.

(a) Starting with 1.5 mg of this isotope, what mass (mg) remains after 49.2 years?

(b) How long will it take for a sample of tritium to decay to one eighth of its activity?

(c) Estimate the length of time necessary for the sample to decay to 1% of its original activity.

Kinetics of Nuclear Decay

The rate of nuclear decay is determined from measurements of the **activity** (A) of a sample. Activity refers to the number of disintegrations observed per unit of time, a quantity that can be measured readily with devices such as a Geiger–Müller counter (Figure 25.6). *Activity is proportional to the number of radioactive atoms present (N).*

$$A \propto N \tag{25.2}$$

If the number of radioactive nuclei N is reduced by half, the activity of the sample will be half as large. Doubling N will double the activity. This relationship indicates that the rate of decomposition is first order with respect to N. Consequently, the equations describing rates of radioactive decay are the same as those used to describe the kinetics of first-order chemical reactions; the change in the number of radioactive atoms N per unit of time is proportional to N (◀ Section 14-4)

$$\frac{\Delta N}{\Delta t} = -kN \tag{25.3}$$

The integrated rate equation can be written in two ways depending on the data used:

$$\ln\left(\frac{N}{N_0}\right) = -kt \tag{25.4}$$

or

$$\ln\left(\frac{A}{A_0}\right) = -kt \tag{25.5}$$

Here, N_0 and A_0 are the number of atoms and the initial activity of the sample, respectively, and N and A are the number of atoms and the activity of the sample after time t, respectively. Thus, N/N_0 is the fraction of atoms remaining after a given time (t), and A/A_0 is the fraction of the activity remaining after the same period. In these equations, k is the rate constant (decay constant) for the isotope in question. The relationship between half-life and the first-order rate constant is the same as seen with chemical kinetics (◀ Equation 14.4):

$$t_{1/2} = \frac{0.693}{k} \tag{25.6}$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equations 25.3–25.6 are useful in several ways:

- If the activity (A) or the number of radioactive nuclei (N) is measured in the laboratory over some period t, k can be calculated. The decay constant k can then be used to determine the half-life of the sample.
- If k is known, the fraction of a radioactive sample (N/N_0) still present after some time t has elapsed can be calculated.
- If k is known, the time required for that isotope to decay to a fraction of the original activity (A/A_0) can be calculated.

EXAMPLE 25.6

Kinetics of Radioactive Decay

Problem A sample of radon-222 has an initial α-particle activity (A_0) of 7.0×10^4 dps (disintegrations per second). After 6.6 days, its activity (A) is 2.1×10^4 dps. What is the half-life of radon-222?

What Do You Know? You are given the initial and final activities of the sample of ^{222}Rn and the time elapsed.

Strategy Values for A, A_0, and t are given. The problem can be solved using Equation 25.5 with k as the unknown. Once k is found, the half-life can be calculated using Equation 25.6.

Solution

$$\ln(2.1 \times 10^4 \text{ dps}/7.0 \times 10^4 \text{ dps}) = -k\,(6.6 \text{ day})$$

$$\ln(0.30) = -k(6.6 \text{ day})$$

$$k = 0.18 \text{ days}^{-1}$$

From k we obtain $t_{1/2}$:

$$t_{1/2} = 0.693/0.18 \text{ days}^{-1} = 3.8 \text{ days}$$

Think about Your Answer Notice that the activity decreased to between one half and one fourth of its original value. The 6.6 days of elapsed time represents one full half-life and part of another half-life.

Check Your Understanding

(a) A sample of $Ca_3(PO_4)_2$ containing phosphorus-32 has an activity of 3.35×10^3 dpm. Exactly 2 days later, the activity is 3.18×10^3 dpm. Calculate the half-life of phosphorus-32.

(b) A highly radioactive sample of nuclear waste products with a half-life of 200. years is stored in an underground tank. How long will it take for the activity to diminish from an initial activity of 6.50×10^{12} dpm to a fairly harmless activity of 3.00×10^3 dpm?

Radiocarbon Dating

In certain situations, the age of a material can be determined based on the rate of decay of a radioactive isotope. The best-known example of this procedure is the use of carbon-14 to date historical artifacts.

Naturally occurring carbon is primarily carbon-12 and carbon-13 with isotopic abundances of 98.9% and 1.1%, respectively. In addition, traces of a third isotope, carbon-14, are present to the extent of about 1 in 10^{12} atoms in atmospheric CO_2 and in living materials. Carbon-14 is a β emitter with a half-life of 5730 years. A

FIGURE 25.7 Variation of atmospheric carbon-14 activity. The amount of carbon-14 has changed with the variation in cosmic ray activity. To obtain the data for the pre-1990 part of the curve shown in this graph, scientists carried out carbon-14 dating of artifacts for which the age was accurately known (often through written records). Data for this figure were obtained using carbon-14 dating of tree rings.

1-gram sample of carbon from living material will show about 14 disintegrations per minute, not a lot of radioactivity but nevertheless detectable by modern methods.

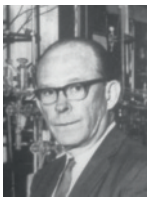
Carbon-14 is formed in the upper atmosphere by nuclear reactions initiated by neutrons in cosmic radiation:

$$^{14}_{7}N + {}^{1}_{0}n \rightarrow {}^{14}_{6}C + {}^{1}_{1}H$$

Once formed, carbon-14 is oxidized to $^{14}CO_2$. This product enters the carbon cycle, circulating through the atmosphere, oceans, and biosphere.

The usefulness of carbon-14 for dating comes about in the following way. Plants absorb CO_2 and convert it to organic compounds, thereby incorporating carbon-14 into living tissue. As long as a plant remains alive, this process will continue, and the percentage of carbon that is carbon-14 in the plant will equal the percentage in the atmosphere. When the plant dies, carbon-14 will no longer be taken up. Radioactive decay continues, however, with the carbon-14 activity decreasing over time. After 5730 years, the activity will be 7 dpm/g; after 11,460 years, it will be 3.5 dpm/g; and so on. By measuring the activity of a sample, and knowing the half-life of carbon-14, it is possible to calculate when a plant (or a plant-eating animal) died.

As with all experimental procedures, carbon-14 dating has limitations. Although the procedure assumes that the amount of carbon-14 in the atmosphere hundreds or thousands of years ago was the same as it is now, in fact the percentage has varied by as much as 10% (Figure 25.7). Furthermore, it is not possible to use carbon-14 to date an object less than about 100 years old; the radiation level from carbon-14 will not change enough in this short time period to permit accurate detection of a difference from the initial value. In most instances, the accuracy of the measurement is, in fact, only about ±100 years. Finally, it is not possible to determine ages of objects much older than about 60,000 years. By then, after more than 10 half-lives, the ^{14}C radioactivity will have decreased virtually to zero. But for the span of time between 100 and 60,000 years, this technique has provided important information (Figure 25.8).



Oesper Collection in the History of Chemistry, University of Cincinnati

Willard Libby (1908–1980) Libby received the 1960 Nobel Prize in Chemistry for developing carbon-14 dating techniques. Carbon-14 dating is widely used in fields such as anthropology.

York, came from the tomb of Zoser, the first Egyptian pharaoh to be entombed in a pyramid. The cyprus wood was from the tomb of Sneferu.) The average activity based on five determinations on one of these wood samples was 7.04 dpm per gram of carbon. Assume (as Arnold and Libby did) that the original activity of carbon-14, A_0, was 12.6 dpm per gram of carbon. Calculate the approximate age of the sample.

What Do You Know? You are given the initial and final ^{14}C activity. The first-order rate constant can be calculated from the half-life.

Strategy First, determine the rate constant for the decay of carbon-14 from its half-life ($t_{1/2}$ for ^{14}C is 5.73×10^3 years). Then, use Equation 25.5.

Solution

$$k = 0.693/t_{1/2} = 0.693/5730 \text{ yr}$$

$$= 1.21 \times 10^{-4} \text{ yr}^{-1}$$

$$\ln(A/A_0) = -kt$$

$$\ln\left(\frac{7.04 \text{ dpm/g}}{12.6 \text{ dpm/g}}\right) = (-1.21 \times 10^{-4} \text{ yr}^{-1})t$$

$$t = 4.8 \times 10^3 \text{ yr}$$

The wood is about 4800 years old.

Think about Your Answer This problem uses real data from an early research paper in which the carbon-14 dating method was being tested. The age of the wood was known to be 4750 ± 250 years. (See J. R. Arnold and W. F. Libby: *Science,* Vol. 110, p. 678, 1949.)

Check Your Understanding

A sample of the inner part of a redwood tree felled in 1874 was shown to have ^{14}C activity of 9.32 dpm/g. Calculate the approximate age of the tree when it was cut down. Compare this age with that obtained from tree ring data, which estimated that the tree began to grow in 979 ± 52 BC. Use 13.4 dpm/g for the value of A_0.

REVIEW & CHECK FOR SECTION 25-4

1. The age of the Earth is thought to be 4.5 billion years. Approximately what percentage of ^{232}Th has decomposed during this period of time? The half-life of ^{232}Th is 1.4×10^{10} years.

Lawrence Berkeley Laboratory

Glenn T. Seaborg (1912–1999)
Seaborg figured out that thorium and the elements that followed it fit under the lanthanides in the periodic table. For this insight, he and Edwin McMillan shared the 1951 Nobel Prize in Chemistry. Over a 21-year period, Seaborg and his colleagues synthesized 10 new transuranium elements. To honor Seaborg's scientific contributions, the name "seaborgium" was assigned to element 106 in 1997. It marked the first time an element was named for a living person.

25-5 Artificial Nuclear Reactions

How many different isotopes are found on Earth? All of the stable isotopes occur naturally as well as a few unstable (radioactive) isotopes that have long half-lives; the best-known examples of the latter type are uranium-235, uranium-238, and thorium-232. Trace quantities of other radioactive isotopes with short half-lives are also present because they are being formed continuously by nuclear reactions. These include isotopes of radium, polonium, and radon, along with other elements

A CLOSER LOOK — The Search for New Elements

By 1936, guided first by Mendeleev's predictions and later by atomic theory, chemists had identified all but two of the elements with atomic numbers between 1 and 92. From this point onward, all new elements to be discovered came from artificial nuclear reactions. Two gaps in the periodic table were filled when radioactive technetium and promethium, the last two elements with atomic numbers less than 92, were identified in 1937 and 1942, respectively. The first success in the search for elements with atomic numbers higher than 92 came with the 1940 discovery of neptunium and plutonium.

Since 1950, laboratories in the United States (Lawrence Berkeley National Laboratory), Russia (Joint Institute for Nuclear Research at Dubna, near Moscow), and Europe (Institute for Heavy Ion Research at Darmstadt, Germany) have competed to make new elements. Syntheses of new transuranium elements use a standard methodology. An element of fairly high atomic number is bombarded with a beam of high-energy particles. Initially, neutrons were used; later, helium nuclei and then larger nuclei such as ^{11}B and ^{12}C were used; and, more recently, highly charged ions of elements such as calcium, chromium, cobalt, and zinc have been chosen. The bombarding particle fuses with the nucleus of the target atom, forming a new nucleus that lasts for a short time before decomposing. New elements are detected by their decomposition products, a signature of particles with specific masses and energies.

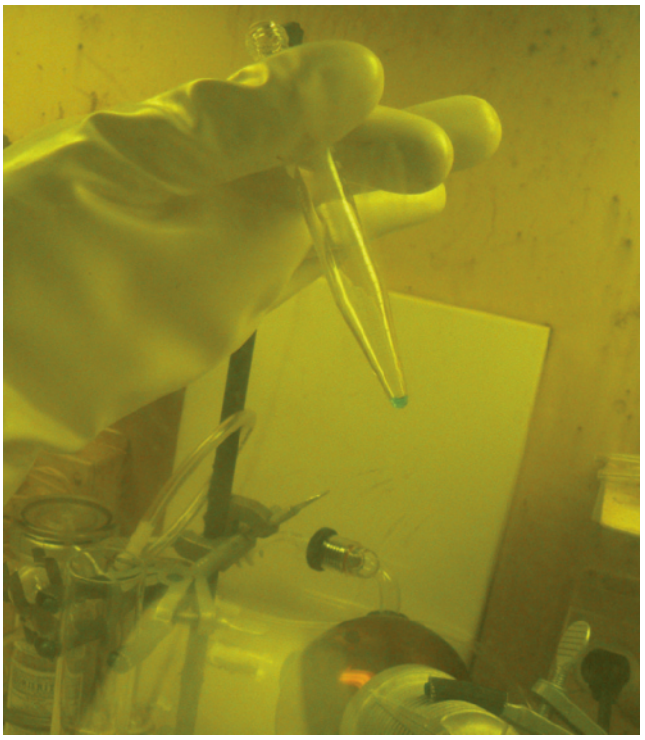
By using bigger particles and higher energies, the list of known elements reached 106 by the end of the 1970s. To further extend the search, Russian scientists used a new idea, precisely matching the energy of the bombarding particle with the energy required to fuse the nuclei. This technique enabled the synthesis of elements 107, 108, and 109 in Darmstadt in the early 1980s, and the synthesis of elements 110, 111, and 112 in the following decade. Lifetimes of these elements were in the millisecond range; copernicium-277, $^{277}_{112}Cn$, for example, has a half-life of 240 μs.

Yet another breakthrough was needed to extend the list further. Scientists have long known that isotopes with specific so-called *magic numbers* of neutrons and protons are more stable. Elements with 2, 8, 20, 50, and 82 protons are members of this category, as are elements with 126 neutrons. The magic numbers correspond to filled shells in the nucleus. Their significance is analogous to the significance of filled shells for electronic structure. Theory had predicted that the next magic numbers would be 114 protons and 184 neutrons. Using this information, researchers discovered element 114 in early 1999. The Dubna group reporting this discovery found that the mass 289 isotope had an exceptionally long half-life, about 20 seconds. The element was recently named flerovium, Fl, after the name of the laboratory in Dubna, Russia.

Element 116 was discovered in 1999 and is now named livermorium, Lv, for the laboratory in Berkeley, California. About 35 atoms of Lv have been obtained with the longest-lived isotope, Lv-293, having a half-life of about 60 ms.

The discovery of element 117, Uus, was announced in April 2010 by an international team at the Flerov Laboratories in Dubna, Russia. They obtained 6 atoms of the element by bombarding ^{249}Bk with ^{48}Ca atoms.

Finally, several atoms of element 118, *which completes row 7 of the periodic table,* were discovered in 2006 by bombarding atoms of californium-249 with atoms of calcium-48.



Jim Roberto/Department of Energy/ORNL

Discovery of element 117, Fl, flerovium. Scientists at the Flerov Laboratories in Dubna, Russia, used radioactive berkelium-249 as the starting material to make two isotopes of element 117. Berkelium-249 is contained in the greenish fluid in the tip of the vial. It was made in the research reactor at Oak Ridge National Laboratory.

produced in various radioactive decay series, and carbon-14, formed in a nuclear reaction initiated by cosmic radiation.

Naturally occurring isotopes account for only a very small fraction of the currently known radioactive isotopes, however. The rest—several thousand—have been synthesized via artificial nuclear reactions, sometimes referred to as *transmutation*.

The first artificial nuclear reaction was identified by Rutherford about 90 years ago. Recall the classic experiment that led to the nuclear model of the atom (◀ *Key Experiments—How Do We Know the Nature of the Atom and its Components,* Chapter 2) in which gold foil was bombarded with α particles. In the years following that experiment, Rutherford and his coworkers bombarded many other elements with α particles. In 1919, one of these experiments led to an unexpected result: When nitrogen atoms were bombarded with α particles, protons were detected among the products. Rutherford correctly concluded that a nuclear reaction had occurred. Nitrogen had undergone a *transmutation* to oxygen:

$$^{4}_{2}\text{He} + {}^{14}_{7}\text{N} \rightarrow {}^{17}_{8}\text{O} + {}^{1}_{1}\text{H}$$

During the next decade, other nuclear reactions were discovered by bombarding other elements with α particles. Progress was slow, however, because in most cases α particles are simply scattered by target nuclei. The bombarding particles cannot get close enough to the nucleus to react because of the strong repulsive forces between the positively charged α particle and the positively charged atomic nucleus.

Discovery of Neutrons Neutrons had been predicted to exist for more than a decade before they were identified in 1932 by James Chadwick (1891–1974). Chadwick produced neutrons in a nuclear reaction between α particles and beryllium: $^{4}_{2}\alpha + {}^{9}_{4}\text{Be} \rightarrow {}^{12}_{6}\text{C} + {}^{1}_{0}\text{n}$.

Two advances were made in 1932 that greatly extended nuclear reaction chemistry. The first involved the use of particle accelerators to create high-energy particles as projectiles. The second was the use of neutrons as the bombarding particles.

The α particles used in the early studies on nuclear reactions came from naturally radioactive materials such as uranium and had relatively low energies. Particles with higher energy were needed, so J. D. Cockcroft (1897–1967) and E. T. S. Walton (1903–1995), working in Rutherford's laboratory in Cambridge, England, turned to protons. Protons are formed when hydrogen atoms ionize in a cathode-ray tube, and it was known that they could be accelerated to higher energy by applying a high voltage. Cockcroft and Walton found that when energetic protons struck a lithium target, the following reaction occurs:

$$^{7}_{3}\text{Li} + {}^{1}_{1}\text{p} \rightarrow 2\ {}^{4}_{2}\text{He}$$

This was the first example of a reaction initiated by a particle that had been artificially accelerated to high energy. Since this experiment was done, the technique has been developed much further, and the use of particle accelerators in nuclear chemistry is now commonplace. Particle accelerators operate on the principle that a charged particle placed between charged plates will be accelerated to a high speed and high energy. Modern examples of this process are seen in the synthesis of the transuranium elements, several of which are described in more detail in *A Closer Look: The Search for New Elements*, on the previous page.

Transuranium Elements in Nature Neptunium, plutonium, and americium were unknown prior to their preparation via these nuclear reactions. Later, these elements were found to be present in trace quantities in uranium ores.

Experiments using neutrons as bombarding particles were first carried out in both the United States and Great Britain in 1932. Nitrogen, oxygen, fluorine, and neon were bombarded with energetic neutrons, and α particles were detected among the products. Using neutrons made sense: Because neutrons have no charge, it was reasoned that these particles would not be repelled by the positively charged nuclear particles. Thus, neutrons did not need high energies to react.

In 1934, Enrico Fermi (1901–1954) and his coworkers showed that nuclear reactions using neutrons are more favorable if the neutrons have low energy. A low-energy neutron is simply captured by the nucleus, giving a product in which the mass number is increased by one unit. Because of the low energy of the bombarding particle, the product nucleus does not have sufficient energy to fragment in these reactions. The new nucleus is produced in an excited state, however; when the nucleus returns to the ground state, a γ ray is emitted. Reactions in which a neutron is captured and a γ ray is emitted are called **(n, γ) reactions**.

The (n, γ) reactions are the source of many of the radioisotopes used in medicine and chemistry. An example is radioactive phosphorus, $^{32}_{15}\text{P}$, which is used in chemical studies such as tracing the uptake of phosphorus in the body.

$$^{31}_{15}\text{P} + {}^{1}_{0}\text{n} \rightarrow {}^{32}_{15}\text{P} + \gamma$$

Transuranium elements, elements with an atomic number greater than 92, were first made in a nuclear reaction sequence beginning with an (n, γ) reaction. Scientists at the University of California at Berkeley bombarded uranium-238 with neutrons. Among the products identified were neptunium-239 and plutonium-239. These new elements were formed when ^{239}U decayed by β radiation.

$$^{238}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{239}_{92}\text{U}$$

$$^{239}_{92}\text{U} \longrightarrow {}^{239}_{93}\text{Np} + {}^{0}_{-1}\beta$$

$$^{239}_{93}\text{Np} \longrightarrow {}^{239}_{94}\text{Pu} + {}^{0}_{-1}\beta$$

Four years later, a similar reaction sequence was used to make americium-241. Plutonium-239 was found to add two neutrons to form plutonium-241, which decays by β emission to give americium-241.

EXAMPLE 25.8

Nuclear Reactions

Problem Write equations for the nuclear reactions described below.

(a) Fluorine-19 undergoes an (n, γ) reaction to give a radioactive product that decays by β emission. (Write equations for both nuclear reactions.)

(b) When an atom of beryllium-9 (the only stable isotope of beryllium) reacts with an α particle emitted by a plutonium-239 atom, a neutron is ejected.

What Do You Know? Reactants and one of two products are given for each reaction.

Strategy The equations are written so that both mass and charge are balanced.

Solution

(a) $^{19}_{9}\text{F} + {}^{1}_{0}\text{n} \longrightarrow {}^{20}_{9}\text{F} + \gamma$

$^{20}_{9}\text{F} \longrightarrow {}^{20}_{10}\text{Ne} + {}^{0}_{-1}\beta$

(b) $^{239}_{94}\text{Pu} \longrightarrow {}^{235}_{92}\text{U} + {}^{4}_{2}\alpha$

$^{4}_{2}\alpha + {}^{9}_{4}\text{Be} \longrightarrow {}^{12}_{6}\text{C} + {}^{1}_{0}\text{n}$

Think about Your Answer Both answers deal with neutrons. The equation given for part (a), an (n, γ) reaction, illustrates a process that is easy to carry out. In a lab, the neutrons might be produced in a small device called a *Pu-Be neutron source*. The answer to part (b) of this question describes the nuclear reactions in such a device.

Check Your Understanding

Technetium is one of the two elements with atomic numbers less than 83 for which there is no stable isotope (promethium, element 61, is the other). Nevertheless, technetium is a very important element because of its extensive use in medical imaging (page 1002). It is produced in a two-step process. First, ^{98}Mo undergoes an (n, γ) reaction; then, the resulting unstable isotope decomposes to ^{99}Tc. Write equations for these two reactions.

REVIEW & CHECK FOR SECTION 25-5

1. Which of the following is seldom used as a bombarding particle to initiate a nuclear reaction?

   (a) protons (b) neutrons (c) electrons (d) alpha particles

25-6 Nuclear Fission

The Atomic Bomb In an atomic bomb, each nuclear fission step produces 3 neutrons, which leads to about 3 more fissions and 9 more neutrons, which leads to 9 more fission steps and 27 more neutrons, and so on. The rate of fission depends on the number of neutrons, so the nuclear reaction occurs faster and faster as more and more neutrons are formed, leading to an enormous output of energy in a short time span.

In 1938, two chemists, Otto Hahn (1879–1968) and Fritz Strassman (1902–1980), isolated and identified barium in a sample of uranium that had been bombarded with neutrons. How was barium formed? The answer—that the uranium nucleus had split into smaller pieces in a process we now call **nuclear fission**—was one of the most significant scientific discoveries of the 20th century.

The details of nuclear fission were unraveled through the work of a number of scientists. They determined that a uranium-235 nucleus initially captured a neutron to form uranium-236. This isotope then underwent nuclear fission to produce two new nuclei, one with a mass around 140 and the other with a mass around 90, along with several neutrons (Figure 25.9). The nuclear reactions that led to formation of barium when a sample of ^{235}U was bombarded with neutrons are

$$^{235}_{92}U + {}^{1}_{0}n \rightarrow {}^{236}_{92}U$$

$$^{236}_{92}U \rightarrow {}^{141}_{56}Ba + {}^{92}_{36}Kr + 3\ {}^{1}_{0}n$$

Central Press/Getty Images

Lise Meitner (1878–1968) Meitner's greatest contribution to 20th-century science was her explanation of the process of nuclear fission. She and her nephew, Otto Frisch, also a physicist, published a paper in 1939 that was the first to use the term *nuclear fission*. Element number 109 is named *meitnerium* to honor Meitner's contributions. The leader of the team that discovered this element said that "She should be honored as the most significant woman scientist of [the 20th] century."

An important aspect of fission reactions is that they produce more neutrons than are used to initiate the process. Under the right circumstances, these neutrons then serve to continue the reaction. If one or more of these neutrons are captured by another ^{235}U nucleus, then a further reaction can occur, releasing still more neutrons. This sequence repeats over and over. Such a mechanism, in which each step generates a reactant to continue the reaction, is called a **chain reaction**.

A nuclear fission chain reaction has three general steps:

1. *Initiation*. The reaction of a single atom is needed to start the chain. Fission of ^{235}U is initiated by the absorption of a neutron.
2. *Propagation*. This part of the process repeats itself over and over, with each step yielding more product. The fission of ^{236}U releases neutrons that initiate the fission of other uranium atoms.
3. *Termination*. Eventually, the chain will end. Termination could occur if the reactant (^{235}U) is used up, or if the neutrons that continue the chain escape from the sample without being captured by ^{235}U.

To harness the energy produced in a nuclear reaction, it is necessary to control the rate at which a fission reaction occurs. This is managed by balancing the propagation and termination steps by limiting the number of neutrons available. In a nuclear reactor, this balance is accomplished by using cadmium rods to absorb neutrons. By withdrawing or inserting the rods, the number of neutrons available to propagate the chain can be changed, and the rate of the fission reaction (and the rate of energy production) can be increased or decreased.

Uranium-235 and plutonium-239 are the fissionable isotopes most commonly used in power reactors. Natural uranium contains only 0.72% of uranium-235; more

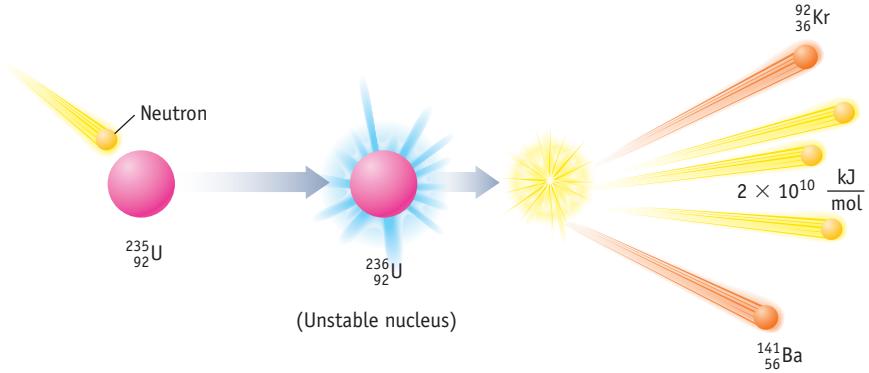

FIGURE 25.9 Nuclear fission. Neutron capture by $^{235}_{92}U$ produces $^{236}_{92}U$. This isotope undergoes fission, which yields several fragments along with several neutrons. These neutrons initiate further nuclear reactions by adding to other $^{235}_{92}U$ nuclei. The process is highly exothermic, producing about 2×10^{10} kJ/mol.

Oak Ridge National Laboratory

Separation of uranium isotopes for use in atomic weaponry or in nuclear power plants is done with gas centrifuges.

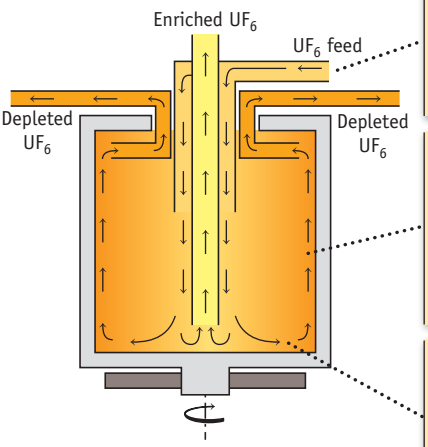

FIGURE 25.10 Isotope separation by gas centrifuge. (See the *New York Times,* page F1, March 23, 2004.)

than 99% of the natural element is uranium-238. The percentage of uranium-235 in natural uranium is too small to sustain a chain reaction, however, so the uranium used for nuclear fuel must be enriched in this isotope. One way to do so is by gaseous centrifugation (Figure 25.10). Plutonium, on the other hand, occurs naturally in only trace quantities and so must be made by a nuclear reaction. The raw material for this nuclear synthesis is the more abundant uranium isotope, ^{238}U. Addition of a neutron to ^{238}U gives ^{239}U, which, as noted earlier, undergoes two β emissions to form ^{239}Pu.

Currently, there are over 100 operating nuclear power plants in the United States and more than 400 worldwide. About 20% of this country's electricity (and 17% of the world's energy) comes from nuclear power (◀ Chapter 20). Although one might imagine that nuclear energy would be called upon to meet the ever-increasing needs of society, only three new nuclear power plants are under construction in the United States. Among other things, the disasters at Chernobyl (in the former Soviet Union) in 1986, Three Mile Island (in Pennsylvania) in 1979, and the Fukushima power plant in Japan (which was damaged by a tsunami in 2011) have sensitized the public to the issue of safety. The cost to construct a nuclear power plant (measured in terms of dollars per kilowatt-hour of power) is considerably more than the cost for a natural gas–powered facility, and there are severe regulatory restrictions for nuclear power. Disposal of highly radioactive nuclear waste is another thorny problem, with 20 metric tons of waste being generated per year at each reactor.

In addition to technical problems, nuclear energy production brings with it significant geopolitical security concerns. The process for enriching uranium for use in a reactor is the same process used for generating weapons-grade uranium. Also, some nuclear reactors are designed so that one by-product of their operation is the isotope plutonium-239, which can be removed and used in a nuclear weapon. Despite these problems, nuclear fission is an important part of the energy profile in a number of countries. For example, about 75% of power production in France and 25% in Japan is nuclear generated.

25-7 Nuclear Fusion

In a **nuclear fusion** reaction, several small nuclei react to form a larger nucleus and generate tremendous amounts of energy. An example is the fusion of deuterium and tritium nuclei to form $^4_2$He and a neutron:

$$^2_1\text{H} + {}^3_1\text{H} \rightarrow {}^4_2\text{He} + {}^1_0\text{n} \qquad \Delta E = -1.7 \times 10^9 \text{ kJ/mol}$$

a reaction that provides the energy of our Sun and other stars.

Scientists have long dreamed of being able to harness fusion to provide power. To do so, a temperature of 10^6 to 10^7 K, like that in the interior of the Sun, would be required to bring the positively charged nuclei together with enough energy to overcome nuclear repulsions. At the very high temperatures needed for a fusion reaction, matter does not exist as atoms or molecules; instead, matter is in the form of a *plasma* made up of unbound nuclei and electrons.

Three critical requirements must be met before nuclear fusion could become a viable energy source. First, the temperature must be high enough for fusion to occur. The fusion of deuterium and tritium, for example, requires a temperature of 10^7 K or more. Second, the plasma must be confined long enough to release a net output of energy. Third, the energy must be recovered in some usable form.

Harnessing a nuclear fusion reaction for a peaceful use has not yet been achieved. Nevertheless, many attractive features encourage continuing research in this field. The hydrogen used as "fuel" is cheap and available in almost unlimited amounts. As a further benefit, most radioisotopes produced by fusion have short half-lives, so they remain a radiation hazard for only a short time.

25-8 Radiation Health and Safety

Units for Measuring Radiation

Several units of measurement are used to describe levels and doses of radioactivity. In the United States, the degree of radioactivity is often measured in **curies** (Ci). Less commonly used in the United States is the SI unit, the **becquerel** (Bq). Both units measure the number of disintegrations per second; 1 Ci is 3.7×10^{10} dps (disintegrations per second), while 1 Bq represents 1 dps. The curie and the becquerel are used to report the amount of radioactivity when multiple kinds of unstable nuclei are decaying and to report amounts necessary for medical purposes.

By itself, the amount of radioactivity does not provide a good measure of the amount of energy in the radiation or the amount of damage that the radiation can cause to living tissue. Two additional kinds of information are necessary. The first is the amount of energy absorbed; the second is the effectiveness of the particular kind of radiation in causing tissue damage. The amount of energy absorbed by living tissue is measured in **rads**. *Rad* is an acronym for "radiation absorbed dose." One rad represents 0.01 J of energy absorbed per kilogram of tissue. Its SI equivalent is the **gray** (Gy); 1 Gy denotes the absorption of 1 J per kilogram of tissue.

Different forms of radiation cause different amounts of biological damage. The amount of damage depends on how strongly a form of radiation interacts with matter. Alpha particles cannot penetrate the body any farther than the outer layer of skin. If α particles are emitted within the body, however, they will cause between 10 and 20 times the amount of damage done by γ rays, which can go entirely through a human body without being stopped. In determining the amount of biological damage to living tissue, differences in damaging power are accounted for using a "quality factor." This quality factor has been set at 1 for β and γ radiation, 5 for low-energy protons and neutrons, and 20 for α particles or high-energy protons and neutrons.

Biological damage is quantified in a unit called the **rem** (an acronym for "roentgen equivalent man"). A dose of radiation in rem is determined by multiplying the energy absorbed in rads by the quality factor for that kind of radiation. The rad and

Units of Radiation The roentgen (R) is an older unit of radiation exposure. It is defined as the amount of x-rays or γ radiation that will produce 2.08×10^9 ions in 1 cm^3 of dry air. The roentgen and the rad are similar in size. Wilhelm Roentgen (1845–1923) first produced and detected x radiation. Element 111 has been named roentgenium in his honor. The curie is named for Marie Curie (1867–1934, page 54), who is also honored by the name given element 96. The becquerel is named for Henri Becquerel (1852–1908), and the sievert is named for a Swedish physicist, Rolf Sievert (1896–1966).

the rem are very large in comparison to normal exposures to radiation, so it is more common to express exposures in millirems (mrem). The SI equivalent of the rem is the **sievert** (Sv), determined by multiplying the dose in grays by the quality factor.

Radiation: Doses and Effects

Exposure to a small amount of radiation is unavoidable. Earth is constantly being bombarded with radioactive particles from outer space. There is also some exposure to radioactive elements that occur naturally on Earth, including ^{14}C, ^{40}K (a radioactive isotope that occurs naturally in 0.0117% abundance), ^{238}U, and ^{232}Th. Radioactive elements in the environment that were created artificially (in the fallout from nuclear bomb tests, for example) also contribute to this exposure. For some people, medical procedures using radioisotopes are a major contributor.

The average dose of background radioactivity to which a person in the United States is exposed is about 200 mrem per year (Table 25.2). Well over half of that amount comes from natural sources over which we have no control. Of the 60–70 mrem per year exposure that comes from artificial sources, nearly 90% is delivered in medical procedures such as x-ray examinations and radiation therapy. Considering the controversy surrounding nuclear power, it is interesting to note that less than 0.5% of the total annual background dose of radiation the average person receives can be attributed to the nuclear power industry.

Table 25.2 Radiation Exposure of an Individual for One Year from Natural and Artificial Sources

	Millirem/Year	Percentage
Natural Sources		
Cosmic radiation	50.0	25.8
The Earth	47.0	24.2
Building materials	3.0	1.5
Inhaled from the air	5.0	2.6
Elements found naturally in human tissue	21.0	10.8
Subtotal	**126.0**	**64.9**
Medical Sources		
Diagnostic x-rays	50.0	25.8
Radiotherapy	10.0	5.2
Internal diagnosis	1.0	0.5
Subtotal	**61.0**	**31.5**
Other Artificial Sources		
Nuclear power industry	0.85	0.4
Luminous watch dials, TV tubes	2.0	1.0
Fallout from nuclear tests	4.0	2.1
Subtotal	**6.9**	**3.5**
Total	**193.9**	**99.9**

A CLOSER LOOK — What Is a Safe Exposure?

Is the exposure to natural background radiation totally without effect? Can you equate the effect of a single dose and the effect of cumulative, smaller doses that are spread out over a long period of time? The assumption generally made is that no "safe maximum dose," or level below which absolutely no damage will occur, exists. However, the accuracy of this assumption has come into question. These issues are not testable with human subjects, and tests based on animal studies are not completely reliable because of the uncertainty of species-to-species variations.

The model used by government regulators to set exposure limits assumes that the relationship between exposure to radiation and incidence of radiation-induced problems, such as cancer, anemia, and immune system problems, is linear. Under this assumption, if a dose of 2*x* rem causes damage in 20% of the population, then a dose of *x* rem will cause damage in 10% of the population. But is this true? Cells do possess mechanisms for repairing damage. Many scientists believe that this self-repair mechanism renders the human body less susceptible to damage from smaller doses of radiation, because the damage will be repaired as part of the normal course of events. They argue that, at extremely low doses of radiation, the self-repair response results in less damage.

The bottom line is that much still remains to be learned in this area. And the stakes are significant.

© Jurgen Schulzki/Alamy

The film badge. These badges, worn by scientists using radioactive materials, are used to monitor cumulative exposure to radiation.

Describing the biological effects of a dose of radiation precisely is not a simple matter. The amount of damage done depends not only on the kind of radiation and the amount of energy absorbed, but also on the particular tissues exposed and the rate at which the dose builds up. A great deal has been learned about the effects of radiation on the human body by studying the survivors of the bombs dropped over Japan in World War II and the workers exposed to radiation from the reactor disaster at Chernobyl. From studies of the health of these survivors, we have learned that the effects of radiation are not generally observable below a single dose of 25 rem. At the other extreme, a single dose of >200 rem will be fatal to about half the population (Table 25.3).

Our information is more accurate when dealing with single, large doses than it is for the effects of chronic, smaller doses of radiation. One current issue of debate in the scientific community is how to judge the effects of multiple smaller doses or long-term exposure.

Table 25.3 Effects of a Single Dose of Radiation

Dose (rem)	Effect
0–25	No effect observed
26–50	Small decrease in white blood cell count
51–100	Significant decrease in white blood cell count, lesions
101–200	Loss of hair, nausea
201–500	Hemorrhaging, ulcers, death in 50% of population
500	Death

25-9 Applications of Nuclear Chemistry

We tend to think about nuclear chemistry in terms of power plants and bombs. In truth, radioactive elements are now used in many areas of science and medicine, and they are of ever-increasing importance to our lives. Because describing all of their uses would take several books, we have selected just a few examples to illustrate the diversity of applications of radioactivity.

Nuclear Medicine: Medical Imaging

Diagnostic procedures using nuclear chemistry are essential in medical imaging, which entails the creation of images of specific parts of the body. There are three principal components to constructing a radioisotope-based image:

- A radioactive isotope, administered as the element or incorporated into a compound that concentrates the radioactive isotope in the tissue to be imaged
- A method of detecting the type of radiation involved
- A computer to assemble the information from the detector into a meaningful image

The choice of a radioisotope and the manner in which it is administered are determined by the tissue in question. A compound containing the isotope must be absorbed more by the target tissue than by the rest of the body. Table 25.4 lists radioisotopes that are commonly used in nuclear imaging processes, their half-lives, and the tissues they are used to image. All the isotopes in Table 25.4 are γ emitters because γ radiation is preferred for imaging; it is less damaging to the body in small doses than either α or β radiation.

Technetium-99m is used in more than 85% of the diagnostic scans done in hospitals each year (see *Case Study: Technetium-99m and Medical Imaging*). The "m" stands for *metastable*, a term used to identify an excited state that exists for a finite period of time. Recall that atoms in excited electronic states emit visible, infrared, and ultraviolet radiation (◀ Chapter 6). Similarly, a nucleus in an excited state gives up its excess energy, but in this case a much higher energy is involved, and the emission occurs as γ radiation.

Another medical imaging technique based on nuclear chemistry is *positron emission tomography* (PET). In PET, an isotope that decays by positron emission is incorporated into a carrier compound and given to the patient. The emitted positron travels no more than a few millimeters before undergoing matter–antimatter annihilation.

$$ {}^{0}_{+1}\beta + {}^{0}_{-1}e \rightarrow 2\gamma $$

Table 25.4 Radioisotopes Used in Medical Diagnostic Procedures

Radioisotope	Half-Life (h)	Imaging
^{99m}Tc	6.0	Thyroid, brain, kidneys
^{201}Tl	73.0	Heart
^{123}I	13.2	Thyroid
^{67}Ga	78.2	Various tumors and abscesses
^{18}F	1.8	Brain, sites of metabolic activity

CASE STUDY

Technetium-99m and Medical Imaging

Technetium was the first new element to be made artificially. One might think that this would make the element a chemical rarity, but this is not so. Technetium is the product of nuclear reactions that can be done in a laboratory. As a consequence it has been readily available and even inexpensive (about $60 per gram). This has also led to widespread use in medical diagnosis, and it is now used all over the world in evaluations of the thyroid gland, the heart, kidneys, and lungs.

Technetium-99m is formed when molybdenum-99 decays by β emission. Technetium-99m (^{99m}Tc) then decays to its ground state (forming ^{99}Tc) with a half-life of 6.01 hours, giving off a 140-KeV γ ray in the process. (Technetium-99 is also radioactive, decaying to stable ^{99}Ru with a half-life of 2.1×10^5 years.)

Molydenum-99 is not a component of naturally occurring molybdenum. It is made in an (n, γ) reaction from molybdenum-98 (23.8% abundant in naturally occurring samples of the element). Nuclear power reactors utilizing U-235 provide the source of neutrons for this synthesis. But there was a problem with this route beginning about 2010 when the main reactors producing the molybdenum (in Canada and The Netherlands) had to be closed for some months for repairs. Because technetium is so important worldwide for medical procedures, scientists immediately began looking for new sources.

Technetium-99m is produced in hospitals using a molybdenum–technetium generator. Shielded in lead, the generator contains the isotope ^{99}Mo in the form of the molybdate ion, MoO_4^{2-}, adsorbed on a column of alumina, Al_2O_3. The MoO_4^{2-} ion is continually converted into the pertechnetate ion, $^{99m}TcO_4^-$ by β emission. When it is needed, the $^{99m}TcO_4^-$ is washed from the column using a saline solution. Technetium-99m may be used directly as the pertechnetate ion (as $NaTcO_4$) or converted into other compounds. The pertechnetate ion or radiopharmaceuticals made from it are administered intravenously to the patient. Such small quantities are needed that 1 μg (microgram) of technetium-99m is sufficient for the average hospital's daily imaging needs.

One use of ^{99m}Tc is for imaging the thyroid gland. Because $I^-(aq)$ and $TcO_4^-(aq)$ ions have very similar sizes, the thyroid will (mistakenly) take up $TcO_4^-(aq)$ along with iodide ion. This uptake concentrates ^{99m}Tc in the thyroid and allows a physician to obtain images such as the one shown here.

Questions:

1. Write an equation for the β decay of ^{99}Mo to ^{99}Tc.
2. What is the oxidation number of Tc in the pertechnetate ion? What is the electron configuration of a Tc^{n+} ion with a charge equal to this oxidation number? Should the TcO_4^- ion be paramagnetic or diamagnetic?
3. What amount of $NaTcO_4$ is there in 1.0 μg of the salt? What mass of Tc?
4. If you have 1.0 μg of Tc, what mass remains at the end of 24 hours?
5. ^{99}Tc decays to ^{99}Ru. What particle is produced in this decay?
6. Speculate on the reason the TcO_4^- ion is held less strongly to a column of Al_2O_3 than in the MoO_4^{2-} ion.

Thyroid imaging with technetium-99m. The radioactive isotope ^{99m}Tc concentrates in sites of high activity. Images of this gland, which is located at the base of the neck, were obtained by recording γ-ray emission after the patient was given radioactive technetium-99m. Current technology creates a computer color-enhanced scan.

The two emitted γ rays travel in opposite directions. By determining where high numbers of γ rays are being emitted, one can construct a map showing where the positron emitter is located in the body.

An isotope often used in PET is ^{15}O. A patient is given gaseous O_2 that contains ^{15}O. This isotope travels throughout the body in the bloodstream, allowing images of the brain and bloodstream to be obtained (Figure 25.11). Because positron emitters are typically very short-lived, PET facilities must be located near a cyclotron where the radioactive nuclei are prepared and then immediately incorporated into a carrier compound.

Nuclear Medicine: Radiation Therapy

To treat most cancers, it is necessary to use radiation that can penetrate the body to the location of the tumor. Gamma radiation from a cobalt-60 source is commonly used. Unfortunately, the penetrating ability of γ rays makes it virtually impossible to destroy diseased tissue without also damaging healthy tissue in the process. Nevertheless, this technique is a regularly sanctioned procedure, and its successes are well known.

Analytical Methods: The Use of Radioactive Isotopes as Tracers

Radioactive isotopes can be used to help determine the fate of compounds in the body or in the environment. In biology, for example, scientists can use radioactive isotopes to measure the uptake of nutrients. Plants take up phosphorus-containing compounds from the soil through their roots. By adding a small amount of radioactive ^{32}P, a β emitter with a half-life of 14.3 days, to fertilizer and then measuring the rate at which the radioactivity appears in the leaves, plant biologists can determine the rate at which phosphorus is taken up. The outcome can assist scientists in identifying hybrid strains of plants that can absorb phosphorus quickly, resulting in faster-maturing crops, better yields per acre, and more food or fiber at less expense.

To measure pesticide levels, a pesticide can be tagged with a radioisotope and then applied to a test field. By counting the disintegrations of the radioactive tracer, information can be obtained about how much pesticide accumulates in the soil, is taken up by the plant, and is carried off in runoff surface water. After these tests are completed, the radioactive isotope decays to harmless levels in a few days or a few weeks because of the short half-lives of the isotopes used.

Boron Neutron Capture Therapy (BNCT) To avoid the side effects associated with more traditional forms of radiation therapy, BNCT is an experimental treatment that has been explored in the last 10 to 15 years. BNCT is unusual in that boron-10, the isotope of boron used as part of the treatment, is not radioactive. This isotope is highly effective in capturing neutrons, however: 2500 times better than boron-11 and eight times better than uranium-235. When the nucleus of a boron-10 atom captures a neutron, the resulting boron-11 nucleus has so much energy that it fragments to form an α particle and a lithium-7 atom. Although the α particles do a great deal of damage, because their penetrating power is so low, the damage remains confined to an area not much larger than one or two cells in diameter.

Analytical Methods: Isotope Dilution

Imagine, for the moment, that you wanted to estimate the volume of blood in an animal subject. How might you do this? Obviously, draining the blood and measuring its volume in volumetric glassware is not a desirable option.

One technique uses a method called *isotope dilution*. In this process, a small amount of radioactive isotope is injected into the bloodstream. After a period of time to allow the isotope to become distributed throughout the body, a blood sample is taken and its radioactivity measured. The calculation used to determine the total blood volume is illustrated in the next example.

EXAMPLE 25.9

Analysis Using Radioisotopes

Problem A 1.00-mL solution containing 0.240 μCi of tritium is injected into a dog's bloodstream. After a period of time to allow the isotope to be dispersed, a 1.00-mL sample

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

of blood is drawn. The radioactivity of this sample is found to be 4.3×10^{-4} μCi/mL. What is the total volume of blood in the dog?

What Do You Know? You know the concentration (activity) and volume of a concentrated solution and you then measure the concentration of the dilute solution. The unknown is the volume of the dilute solution.

Strategy In this problem, we relate the activity of the sample (in Ci) to the amount of the radioisotope present. The total amount of solute is 0.240 μCi, and the concentration (measured on the small sample of blood) is 4.3×10^{-4} μCi/mL. The unknown is the total volume of blood, *V*.

Solution The blood contains a total of 0.240 μCi of radioactive material. Exactly 1.00 mL containing this amount was injected. After dilution in the bloodstream, 1.00 mL of blood, representative of the total volume *V*, is found to have an activity of 4.3×10^{-4} μCi/mL.

$$(0.240\ \mu\text{Ci/mL})(1.00\ \text{mL}) = (4.3 \times 10^{-4}\ \mu\text{Ci/mL})(V)$$

$$V = 560\ \text{mL}$$

Think about Your Answer This is solved as a classic dilution problem, by equating $C_{dil} \times V_{dil} = C_{conc} \times V_{conc}$

Check Your Understanding

To measure the solubility for $PbCrO_4$ you mix a small amount of a lead(II) salt having radioactive ^{212}Pb with a lead salt containing 0.0100 g of lead. To this mixture you add enough K_2CrO_4 to completely precipitate the lead(II) ions as $PbCrO_4$. The supernatant solution still contains a trace of lead, of course, and when you evaporate 10.00 mL of this solution to solid $PbCrO_4$, you find a radioactivity that is 4.17×10^{-5} of what it is for the pure ^{212}Pb salt. Calculate the solubility of $PbCrO_4$ in mol/L. (Adapted from C. E. Housecraft and A. G. Sharpe, *Inorganic Chemistry,* Pearson, 3rd edition, 2008, p. 84.)

Source: L. A. Haskin, P. A, Helmke, and R. O. Allen: *Science,* Vol. 167, p. 487, 1970. The concentrations of rare earths in moon rocks were quite similar to the values in terrestrial rocks except that the europium concentration is much depleted. The January 30, 1970, issue of *Science* was devoted to analysis of moon rocks.

Space Science: Neutron Activation Analysis and the Moon Rocks

The first manned space mission to the moon brought back a number of samples of soil and rock—a treasure trove for scientists. One of their first tasks was to analyze these samples to determine their identity and composition. Most analytical methods require chemical reactions using at least a small amount of material; however, this was not a desirable option, considering that the moon rocks were at the time the most valuable rocks on Earth.

A few scientists got a chance to work on this unique project, and one of the analytical tools they used was **neutron activation analysis**. In this nondestructive process, a sample is irradiated with neutrons. Most isotopes add a neutron to form a new isotope that is one mass unit higher and in an excited nuclear state. When the nucleus decays to its ground state, it emits a γ ray. The energy of the γ ray identifies the element, and the number of γ rays can be counted to determine the amount of the element in the sample. Using neutron activation analysis, it is possible to analyze for a number of elements in a single experiment (Table 25.5).

Neutron activation analysis has many other uses. This analytical procedure yields a kind of fingerprint that can be used to identify a substance. For example, this technique has been applied in determining whether an art work is real or fraudulent. Analysis of the pigments in paints on a painting can be carried out without damaging the painting to determine whether the composition resembles modern paints or paints used hundreds of years ago.

Food Science: Food Irradiation

Refrigeration, canning, and chemical additives provide significant protection in terms of food preservation, but in some parts of the world these procedures are unavailable, and stored-food spoilage may claim as much as 50% of the food crop. Irradiation with γ rays from sources such as ^{60}Co and ^{137}Cs is an option for prolonging the shelf life of foods. Relatively low levels of radiation may retard the growth of organisms, such as bacteria, molds, and yeasts, that can cause food spoilage. After irradiation, milk in a sealed container has a minimum shelf life of 3 months without refrigeration. Chicken normally has a 3-day refrigerated shelf life; after irradiation, it may have a 3-week refrigerated shelf life.

Higher levels of radiation, in the 1- to 5-Mrad (1 Mrad = 1×10^6 rad) range, will kill every living organism. Foods irradiated at these levels will keep indefinitely when sealed in plastic or aluminum-foil packages. Ham, beef, turkey, and corned beef sterilized by radiation have been used on many Space Shuttle flights, for example. An astronaut said, "The beautiful thing was that it didn't disturb the taste, which made the meals much better than the freeze-dried and other types of foods we had."

These procedures are not without their opponents, and the public has not fully embraced irradiation of foods. An interesting argument favoring this technique is that radiation is less harmful than other methodologies for food preservation. This type of sterilization offers greater safety to food workers because it lessens chances of exposure to harmful chemicals, and it protects the environment by avoiding contamination of water supplies with toxic chemicals.

Food irradiation is commonly used in European countries, Canada, and Mexico. Its use in the United States is currently regulated by the U.S. Food and Drug Administration (FDA) and Department of Agriculture (USDA). In 1997, the FDA approved the irradiation of refrigerated and frozen uncooked meat to control pathogens and extend shelf-life, and in 2000 the USDA approved the irradiation of eggs to control *Salmonella* infection.

"Radura". This international symbol called the "radura" should appear on the packaging of produce (fruits, vegetables, meat) that has been irradiated. See the EPA website for more information: www.epa.gov/radiation/sources/food_irrad.html.

APPLYING CHEMICAL PRINCIPLES

The Age of Meteorites

Meteorites have a significant value for collectors, but they are also of scientific interest. Meteorites are generally regarded as some of the oldest materials in the solar system. And this raises the obvious question: How is the age of a meteorite determined? By age, we are referring to the time since the meteor condensed to a solid, locking the components into a solid matrix so they cannot escape. There are a number of methods to measure the age of a meteor, all involving the decay of long-lived radioactive elements.

One dating procedure involves vaporizing samples of the material and measuring the amounts of ^{86}Sr, ^{87}Sr, and ^{87}Rb by mass spectrometry. Both ^{86}Sr and ^{87}Sr are stable isotopes. The rubidium isotope, which decays to ^{87}Sr, has a half-life of 4.88×10^{10} years. The amount of ^{87}Sr measured includes the

© Denis Scott/CORBIS

Meteorites. Meteorites are materials that originate in outer space and survive the fall to the Earth's surface. They can be large or small, but as they enter Earth's atmosphere they are warmed to a high temperature by friction in the atmosphere and emit light, forming a fireball. There are three general categories: stony meteorites, which are silicate minerals; iron meteorites, largely composed of iron and nickel; and stony-iron meteorites. (See the photo of an iron meteorite, Figure 7.6.)

amount of ^{87}Sr initially present ($^{87}Sr_0$) when the meteorite was formed plus the amount formed by decay of ^{87}Rb. The ^{86}Sr remains constant and is used as a check on the original amounts of the other isotopes. The three measured amounts are related by an equation (which can be derived from the first-order rate law):

$$[^{87}Sr/^{86}Sr] = (e^{kt} - 1)\,[^{87}Rb/^{86}Sr] + [^{87}Sr_0/^{86}Sr]$$

The equation has the form of the equation of a straight line, $y = mx + b$. Multiple samples are analyzed from each meteorite. The amounts of each isotope may vary between samples, but a graph of $[^{87}Sr/^{86}Sr]$ versus $[^{87}Rb/^{86}Sr]$ will give a straight line with a slope $m = (e^{kt} - 1)$ and a y-intercept of $[^{87}Sr_0/^{86}Sr]$. The symbol k refers to the rate constant for the radioactive decomposition. This method is called *isochron dating*.

QUESTIONS:

1. Write a balanced equation for the radioactive decomposition of ^{87}Rb.
2. The decomposition of ^{87}Rb occurs by which of the following processes?
   (a) alpha emission
   (b) beta emission
   (c) gamma emission
   (d) electron capture
   (e) positron emission
3. Determine the rate constant for the radioactive decay of ^{87}Rb.
4. The oldest dated meteorites have ages of about 4.5 billion years. What fraction of the initial ^{87}Rb has decayed?
5. The relative abundances of ^{86}Sr, ^{87}Sr, and ^{87}Rb were measured for four samples of a meteorite; the results were tabulated below. Make a strontium-rubidium isochron plot of these data, then use the slope of the line to determine the age of the meteorite.

RELATIVE ABUNDANCE

SAMPLE #	^{86}Sr	^{87}Sr	^{87}Rb
1	1.000	0.819	0.839
2	1.063	0.855	0.506
3	0.950	0.824	1.929
4	1.011	0.809	0.379

6. Derive the equation given above for $[^{87}Sr/^{86}Sr]$. (*Hint:* Start with the rate equation in the form $[^{87}Rb_0] = [^{87}Rb]\,e^{kt}$.)

CHAPTER GOALS REVISITED

Now that you have studied this chapter, you should ask whether you have met the chapter goals. In particular, you should be able to:

UNDERSTAND

- The criteria for nuclear stability and the processes by which unstable nuclides decay (Figure 25.3 and Section 25-3). Study Questions: 4, 17–22.
- The methods used to synthesize new isotopes of the elements (Section 25-5). Study Questions: 5, 39–43, 48.
- The plot showing numbers of protons and neutrons in stable and unstable nuclides (Section 25-3 and Figure 25.3). Study Question: 4.
- The graph showing binding energy per nucleon versus atomic number (Section 25-3 and Figure 25.4). Study Question: 3.
- Issues of safety and health with respect to radioactivity (Section 25-8). Study Question: 10.
- Uses of radioactive isotopes in science and medicine (Section 25-9).

DO

- Write equations for the decay of radioactive elements and the synthesis of new isotopes (Section 25-2). Study Questions: 11–16, 32, 41.
- Predict possible modes of decomposition of unstable nuclei based on n/p ratios (Sections 25-2 and 25-3). Study Questions: 17–22.
- Calculate the binding energy and binding energy per nucleon for a particular isotope (Section 25-3). Study Questions: 23–28, 52.
- Carry out calculations based on equations for the first-order rate of decomposition of unstable isotopes (Section 25-4). Study Questions: 29–38, 47, 50, 54, 58.

REMEMBER

- Nuclear decay series and their implications (Section 25-2). Study Questions: 9, 15, 16.
- Types of radiation (Sections 25-1 and 25-2).
- The processes of fission and fusion (Sections 25-6 and 25-7).

KEY EQUATIONS

Equation 25.1 (page 985): The equation relating interconversion of mass (m) and energy (E). This equation is applied in the calculation of binding energy (E_b) for nuclei.

$$E_b = (\Delta m)c^2$$

Equation 25.2 (page 989): The activity of a radioactive sample (A) is proportional to the number of radioactive atoms (N).

$$A \propto N$$

Equation 25.3 (page 989): The change in the number of radioactive elements with time is equal to the product of the rate constant (k, decay constant) and number of atoms present (N).

$$\Delta N/\Delta t = -kN$$

Equation 25.4 (page 989): The rate law for nuclear decay based on number of radioactive atoms initially present (N_0) and the number N after time t.

$$\ln(N/N_0) = -kt$$

Equation 25.5 (page 989): The rate law for nuclear decay based on the measured activity of a sample (A).

$$\ln(A/A_0) = -kt$$

Equation 25.6 (page 989): The relationship between the half-life and the rate constant for a nuclear decay process.

$$t_{1/2} = 0.693/k$$

▲ denotes challenging questions.

Blue-numbered questions have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Important Concepts

1. Some important discoveries in scientific history that contributed to the development of nuclear chemistry are listed below. Briefly, describe each discovery, identify prominent scientists who contributed to it, and comment on the significance of the discovery to the development of this field.

(a) 1896, the discovery of radioactivity
(b) 1898, the identification of radium and polonium
(c) 1919, the first artificial nuclear reaction
(d) 1932, (n, γ) reactions
(e) 1939, fission reactions

2. In Chapter 3, the law of conservation of mass was introduced as an important principle in chemistry. The discovery of nuclear reactions forced scientists to modify this law. Explain why, and give an example illustrating that mass is not conserved in a nuclear reaction.

3. A graph of binding energy per nucleon is shown in Figure 25.4. Explain how the data used to construct this graph were obtained.

4. How is Figure 25.3 used to predict the type of decomposition for unstable (radioactive) isotopes?

5. Outline how nuclear reactions are carried out in the laboratory. Describe the artificial nuclear reactions used to make an element with an atomic number greater than 92.

6. What mathematical equations define the rates of decay for radioactive elements?

7. Explain how carbon-14 is used to estimate the ages of archeological artifacts. What are the limitations for use of this technique?

8. Describe how the concept of half-life for nuclear decay is used.

9. What is a radioactive decay series? Explain why radium and polonium are found in uranium ores.

10. The interaction of radiation with matter has both positive and negative consequences. Discuss briefly the hazards of radiation and the way that radiation can be used in medicine.

Nuclear Reactions

(See Section 25-2 and Examples 25.1 and 25.2.)

11. Complete the following nuclear equations. Write the mass number and atomic number for the remaining particle, as well as its symbol.

(a) $^{54}_{26}\text{Fe} + {}^{4}_{2}\text{He} \longrightarrow 2\ {}^{1}_{0}\text{n} + ?$
(b) $^{27}_{13}\text{Al} + {}^{4}_{2}\text{He} \longrightarrow {}^{30}_{15}\text{P} + ?$
(c) $^{32}_{16}\text{S} + {}^{1}_{0}\text{n} \longrightarrow {}^{1}_{1}\text{H} + ?$
(d) $^{96}_{42}\text{Mo} + {}^{2}_{1}\text{H} \longrightarrow {}^{1}_{0}\text{n} + ?$
(e) $^{98}_{42}\text{Mo} + {}^{1}_{0}\text{n} \longrightarrow {}^{99}_{43}\text{Tc} + ?$
(f) $^{18}_{9}\text{F} \longrightarrow {}^{18}_{8}\text{O} + ?$

12. Complete the following nuclear equations. Write the mass number, atomic number, and symbol for the remaining particle.

(a) $^{9}_{4}\text{Be} + ? \longrightarrow {}^{6}_{3}\text{Li} + {}^{4}_{2}\text{He}$
(b) $? + {}^{1}_{0}\text{n} \longrightarrow {}^{24}_{11}\text{Na} + {}^{4}_{2}\text{He}$
(c) $^{40}_{20}\text{Ca} + ? \longrightarrow {}^{40}_{19}\text{K} + {}^{1}_{1}\text{H}$
(d) $^{241}_{95}\text{Am} + {}^{4}_{2}\text{He} \longrightarrow {}^{243}_{97}\text{Bk} + ?$
(e) $^{246}_{96}\text{Cm} + {}^{12}_{6}\text{C} \longrightarrow 4\ {}^{1}_{0}\text{n} + ?$
(f) $^{238}_{92}\text{U} + ? \longrightarrow {}^{249}_{100}\text{Fm} + 5\ {}^{1}_{0}\text{n}$

13. Complete the following nuclear equations. Write the mass number, atomic number, and symbol for the remaining particle.

(a) $^{111}_{47}\text{Ag} \longrightarrow {}^{111}_{48}\text{Cd} + ?$
(b) $^{87}_{36}\text{Kr} \longrightarrow {}^{0}_{-1}\beta + ?$
(c) $^{231}_{91}\text{Pa} \longrightarrow {}^{227}_{89}\text{Ac} + ?$
(d) $^{230}_{90}\text{Th} \longrightarrow {}^{4}_{2}\text{He} + ?$
(e) $^{82}_{35}\text{Br} \longrightarrow {}^{82}_{36}\text{Kr} + ?$
(f) $? \longrightarrow {}^{24}_{12}\text{Mg} + {}^{0}_{-1}\beta$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

14. Complete the following nuclear equations. Write the mass number, atomic number, and symbol for the remaining particle.

(a) $^{19}_{10}\text{Ne} \longrightarrow {}^{0}_{+1}\beta + ?$

(b) $^{59}_{26}\text{Fe} \longrightarrow {}^{0}_{-1}\beta + ?$

(c) $^{40}_{19}\text{K} \longrightarrow {}^{0}_{-1}\beta + ?$

(d) $^{37}_{18}\text{Ar} + {}^{0}_{-1}\text{e}$ (electron capture) $\longrightarrow ?$

(e) $^{55}_{26}\text{Fe} + {}^{0}_{-1}\text{e}$ (electron capture) $\longrightarrow ?$

(f) $^{26}_{13}\text{Al} \longrightarrow {}^{25}_{12}\text{Mg} + ?$

15. The uranium-235 radioactive decay series, beginning with $^{235}_{92}\text{U}$ and ending with $^{207}_{82}\text{Pb}$, occurs in the following sequence: α, β, α, β, α, α, α, α, β, β, α. Write an equation for each step in this series.

16. The thorium-232 radioactive decay series, beginning with $^{232}_{90}\text{Th}$ and ending with $^{208}_{82}\text{Pb}$, occurs in the following sequence: α, β, β, α, α, α, α, β, β, α. Write an equation for each step in this series.

Nuclear Stability and Nuclear Decay

(See Section 25-3 and Examples 25.3 and 25.4.)

17. What particle is emitted in the following nuclear reactions? Write an equation for each reaction.

(a) Gold-198 decays to mercury-198.
(b) Radon-222 decays to polonium-218.
(c) Cesium-137 decays to barium-137.
(d) Indium-110 decays to cadmium-110.

18. What is the product of the following nuclear decay processes? Write an equation for each process.

(a) Gallium-67 decays by electron capture.
(b) Potassium-38 decays with positron emission.
(c) Technetium-99m decays with γ emission.
(d) Manganese-56 decays by β emission.

19. Predict the probable mode of decay for each of the following radioactive isotopes, and write an equation to show the products of decay.

(a) bromine-80
(b) californium-240
(c) cobalt-61
(d) carbon-11

20. Predict the probable mode of decay for each of the following radioactive isotopes, and write an equation to show the products of decay.

(a) manganese-54
(b) americium-241
(c) silver-110
(d) mercury-197m

21. (a) Which of the following nuclei decay by $^{0}_{-1}\beta$ decay?

^{3}H ^{16}O ^{20}F ^{13}N

(b) Which of the following nuclei decays by $^{0}_{+1}\beta$ decay?

^{238}U ^{19}F ^{22}Na ^{24}Na

22. (a) Which of the following nuclei decay by $^{0}_{-1}\beta$ decay?

^{1}H ^{23}Mg ^{32}P ^{20}Ne

(b) Which of the following nuclei decay by $^{0}_{+1}\beta$ decay?

^{235}U ^{35}Cl ^{38}K ^{24}Na

23. Boron has two stable isotopes, ^{10}B and ^{11}B. Calculate the binding energies per mole of nucleons of these two nuclei. The required masses (in g/mol) are $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, $^{10}_{5}\text{B} = 10.01294$, and $^{11}_{5}\text{B} = 11.00931$.

24. Calculate the binding energy in kilojoules per mole of nucleons of P for the formation of ^{30}P and ^{31}P. The required masses (in g/mol) are $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, $^{30}_{15}\text{P} = 29.97832$, and $^{31}_{15}\text{P} = 30.97376$.

25. Calculate the binding energy per mole of nucleons for calcium-40, and compare your result with the value in Figure 25.4. Masses needed for this calculation are (in g/mol) $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, and $^{40}_{20}\text{Ca} = 39.96259$.

26. Calculate the binding energy per mole of nucleons for iron-56. Masses needed for this calculation (in g/mol) are $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, and $^{56}_{26}\text{Fe} = 55.9349$. Compare the result of your calculation to the value for iron-56 in the graph in Figure 25.4.

27. Calculate the binding energy per mole of nucleons for $^{16}_{8}\text{O}$. Masses needed for this calculation are $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, and $^{16}_{8}\text{O} = 15.99492$.

28. Calculate the binding energy per mole of nucleons for nitrogen-14. The mass of nitrogen-14 is 14.003074.

Rates of Radioactive Decay

(See Section 25-4 and Examples 25.5–25.7.)

29. Copper(II) acetate containing ^{64}Cu is used to study brain tumors. This isotope has a half-life of 12.7 hours. If you begin with 25.0 μg of ^{64}Cu, what mass remains after 63.5 hours?

30. Gold-198 is used in the diagnosis of liver problems. The half-life of ^{198}Au is 2.69 days. If you begin with 2.8 μg of this gold isotope, what mass remains after 10.8 days?

31. Iodine-131 is used to treat thyroid cancer.

(a) The isotope decays by β-particle emission. Write a balanced equation for this process.
(b) Iodine-131 has a half-life of 8.04 days. If you begin with 2.4 μg of radioactive ^{131}I, what mass remains after 40.2 days?

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

32. Phosphorus-32 is used in the form of Na_2HPO_4 in the treatment of chronic myeloid leukemia, among other things.
(a) The isotope decays by β-particle emission. Write a balanced equation for this process.
(b) The half-life of ^{32}P is 14.3 days. If you begin with 4.8 μg of radioactive ^{32}P in the form of Na_2HPO_4, what mass remains after 28.6 days (about 1 month)?

33. Gallium-67 ($t_{½}$ = 78.25 hours) is used in the medical diagnosis of certain kinds of tumors. If you ingest a compound containing 0.015 mg of this isotope, what mass (in milligrams) remains in your body after 13 days? (Assume none is excreted.)

34. Iodine-131 ($t_{½}$ = 8.04 days), a β emitter, is used to treat thyroid cancer.
(a) Write an equation for the decomposition of ^{131}I.
(b) If you ingest a sample of NaI containing ^{131}I, how much time is required for the activity to decrease to 35.0% of its original value?

35. Radon has been the focus of much attention recently because it is often found in homes. Radon-222 emits α particles and has a half-life of 3.82 days.
(a) Write a balanced equation to show this process.
(b) How long does it take for a sample of ^{222}Rn to decrease to 20.0% of its original activity?

36. Strontium-90 is a hazardous radioactive isotope that resulted from atmospheric testing of nuclear weapons. A sample of strontium carbonate containing ^{90}Sr is found to have an activity of 1.0×10^3 dpm. One year later, the activity of this sample is 975 dpm.
(a) Calculate the half-life of strontium-90 from this information.
(b) How long will it take for the activity of this sample to drop to 1.0% of the initial value?

37. Radioactive cobalt-60 is used extensively in nuclear medicine as a γ-ray source. It is made by a neutron capture reaction from cobalt-59 and is a β emitter; β emission is accompanied by strong γ radiation. The half-life of cobalt-60 is 5.27 years.
(a) How long will it take for a cobalt-60 source to decrease to one eighth of its original activity?
(b) What fraction of the activity of a cobalt-60 source remains after 1.0 year?

38. Scandium occurs in nature as a single isotope, scandium-45. Neutron irradiation produces scandium-46, a β emitter with a half-life of 83.8 days. If the initial activity is 7.0×10^4 dpm, draw a graph showing disintegrations per minute as a function of time during a period of 1 year.

Nuclear Reactions

(See Section 25-5 and Example 25.9.)

39. Americium-240 is made by bombarding plutonium-239 with α particles. In addition to ^{240}Am, the products are a proton and two neutrons. Write a balanced equation for this process.

40. There are two isotopes of americium, both with half-lives sufficiently long to allow the handling of large quantities. Americium-241, with a half-life of 432 years, is an α emitter used in smoke detectors. The isotope is formed from ^{239}Pu by absorption of two neutrons followed by emission of a β particle. Write a balanced equation for this process.

41. The superheavy element ^{287}Fl (element 114) was made by firing a beam of ^{48}Ca ions at ^{242}Pu. Three neutrons were ejected in the reaction. Write a balanced nuclear equation for the synthesis of ^{287}Fl.

42. To synthesize the heavier transuranium elements, a nucleus must be bombarded with a relatively large particle. If you know the products are californium-246 and four neutrons, with what particle would you bombard uranium-238 atoms?

43. Deuterium nuclei (^2_1H) are particularly effective as bombarding particles to carry out nuclear reactions. Complete the following equations:
(a) $^{114}_{48}Cd + {}^2_1H \longrightarrow ? + {}^1_1H$
(b) $^6_3Li + {}^2_1H \longrightarrow ? + {}^1_0n$
(c) $^{40}_{20}Ca + {}^2_1H \longrightarrow {}^{38}_{19}K + ?$
(d) $? + {}^2_1H \longrightarrow {}^{65}_{30}Zn + \gamma$

44. Element $^{287}_{114}Fl$ decays by α emission with a half-life of about 5 seconds. Write an equation for this process.

45. Boron is an effective absorber of neutrons. When boron-10 is bombarded by neutrons, an α particle is emitted. Write an equation for this nuclear reaction.

46. Some of the reactions explored by Ernest Rutherford (pages 55 and 994) and others are listed below. Identify the unknown species in each reaction.
(a) $^{14}_7N + {}^4_2He \longrightarrow {}^{17}_8O + ?$
(b) $^9_4Be + {}^4_2He \longrightarrow ? + {}^1_0n$
(c) $? + {}^4_2He \longrightarrow {}^{30}_{15}P + {}^1_0n$
(d) $^{239}_{94}Pu + {}^4_2He \longrightarrow ? + {}^1_0n$

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

47. ▲ A technique to date geological samples uses rubidium-87, a long-lived radioactive isotope of rubidium ($t_{½}$ = 4.8×10^{10} years). Rubidium-87 decays by

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

β emission to strontium-87. If rubidium-87 is part of a rock or mineral, then strontium-87 will remain trapped within the crystalline structure of the rock. The age of the rock dates back to the time when the rock solidified. Chemical analysis of the rock gives the amounts of ^{87}Rb and ^{87}Sr. From these data, the fraction of ^{87}Rb that remains can be calculated. Suppose analysis of a stony meteorite determined that 1.8 mmol of ^{87}Rb and 1.6 mmol of ^{87}Sr (the portion of ^{87}Sr formed by decomposition of ^{87}Rb) were present. Estimate the age of the meteorite. (*Hint:* The amount of ^{87}Rb at t_0 is moles ^{87}Rb + moles ^{87}Sr.)

48. Tritium, $^{3}_{1}$H, is one of the nuclei used in fusion reactions. This isotope is radioactive, with a half-life of 12.3 years. Like carbon-14, tritium is formed in the upper atmosphere from cosmic radiation, and it is found in trace amounts on Earth. To obtain the amounts required for a fusion reaction, however, it must be made via a nuclear reaction. The reaction of $^{6}_{3}$Li with a neutron produces tritium and an α particle. Write an equation for this nuclear reaction.

49. Phosphorus occurs in nature as a single isotope, phosphorus-31. Neutron irradiation of phosphorus-31 produces phosphorus-32, a β emitter with a half-life of 14.28 days. Assume you have a sample containing phosphorus-32 that has a rate of decay of 3.2×10^6 dpm. Draw a graph showing disintegrations per minute as a function of time during a period of 1 year.

50. In June 1972, natural fission reactors, which operated billions of years ago, were discovered in Oklo, Gabon (page 974). At present, natural uranium contains 0.72% ^{235}U. How many years ago did natural uranium contain 3.0% ^{235}U, the amount needed to sustain a natural reactor? ($t_{½}$ for ^{235}U is 7.04×10^8 years.)

51. If a shortage in worldwide supplies of fissionable uranium arose, it would be possible to use other fissionable nuclei. Plutonium, one such fuel, can be made in "breeder" reactors that manufacture more fuel than they consume. The sequence of reactions by which plutonium is made is as follows:

(a) A ^{238}U nucleus undergoes an (n, γ) reaction to produce ^{239}U.
(b) ^{239}U decays by β emission ($t_{½}$ = 23.5 min) to give an isotope of neptunium.
(c) This neptunium isotope decays by β emission to give a plutonium isotope.
(d) The plutonium isotope is fissionable. On collision of one of these plutonium isotopes with a neutron, fission occurs, with at least two neutrons and two other nuclei as products.

Write an equation for each of the nuclear reactions.

52. When a neutron is captured by an atomic nucleus, energy is released as γ radiation. This energy can be calculated based on the change in mass in converting reactants to products.

For the nuclear reaction $^{6}_{3}\text{Li} + {}^{1}_{0}\text{n} \longrightarrow {}^{7}_{3}\text{Li} + \gamma$:

(a) Calculate the energy evolved in this reaction (per atom). Masses needed (in g/mol) are $^{6}_{3}$Li = 6.01512, $^{1}_{0}$n = 1.00867, and $^{7}_{3}$Li = 7.01600.
(b) Use the answer in part (a) to calculate the wavelength of the γ rays emitted in the reaction.

53. The synthesis of livermorium:

(a) Lv-296 is made from the collision of a relatively light atom with curium-248. What is the lighter particle?
(b) Lv-296 is not stable, decaying to Lv-293. What particles are emitted in this process?

54. Although plutonium does not occur naturally on Earth now, it is thought to have been produced in the Oklo reactor (and then decayed). Write balanced nuclear equations for:

(a) the reaction of ^{238}U and a neutron to give ^{239}U
(b) the decay of ^{239}U to ^{239}Np and then to ^{239}Pu by β emission
(c) the decay of ^{239}Pu to ^{235}U by α emission

In the Laboratory

55. A piece of charred bone found in the ruins of a Native American village has a ^{14}C/^{12}C ratio that is 72% of the ratio found in living organisms. Calculate the age of the bone fragment. ($t_{½}$ for ^{14}C is 5.73×10^3 years.)

56. A sample of wood from a Thracian chariot found in an excavation in Bulgaria has a ^{14}C activity of 11.2 dpm/g. Estimate the age of the chariot and the year it was made. ($t_{½}$ for ^{14}C is 5.73×10^3 years, and the activity of ^{14}C in living material is 14.0 dpm/g.)

57. The isotope of polonium that was most likely isolated by Marie Curie in her pioneering studies is polonium-210. A sample of this element was prepared in a nuclear reaction. Initially, its activity (α emission) was 7840 dpm. Measuring radioactivity over time produced the data below. Determine the half-life of polonium-210.

Activity (dpm)	Time (days)
7840	0
7570	7
7300	14
5920	56
5470	72

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

58. Sodium-23 (in a sample of NaCl) is subjected to neutron bombardment in a nuclear reactor to produce ^{24}Na. When removed from the reactor, the sample is radioactive, with β activity of 2.54×10^4 dpm. The decrease in radioactivity over time was studied, producing the following data:

Activity (dpm)	Time (hours)
2.54×10^4	0
2.42×10^4	1
2.31×10^4	2
2.00×10^4	5
1.60×10^4	10
1.01×10^4	20

(a) Write equations for the neutron capture reaction and for the reaction in which the product of this reaction decays by β emission.
(b) Determine the half-life of sodium-24.

59. The age of minerals can sometimes be determined by measuring the amounts of ^{206}Pb and ^{238}U in a sample. This determination assumes that all of the ^{206}Pb in the sample comes from the decay of ^{238}U. The date obtained identifies when the rock solidified. Assume that the ratio of ^{206}Pb to ^{238}U in an igneous rock sample is 0.33. Calculate the age of the rock. ($t_{½}$ for ^{238}U is 4.5×10^9 years.)

60. To measure the volume of the blood system of an animal, the following experiment was done. A 1.0-mL sample of an aqueous solution containing tritium, with an activity of 2.0×10^6 dps, was injected into the animal's bloodstream. After time was allowed for complete circulatory mixing, a 1.0-mL blood sample was withdrawn and found to have an activity of 1.5×10^4 dps. What was the volume of the circulatory system? (The half-life of tritium is 12.3 years, so this experiment assumes that only a negligible amount of tritium has decayed in the time of the experiment.)

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

61. The average energy output of a good grade of coal is 2.6×10^7 kJ/ton. Fission of 1 mol of ^{235}U releases 2.1×10^{10} kJ. Find the number of tons of coal needed to produce the same energy as 1 lb of ^{235}U. (See Appendix C for conversion factors.)

62. Collision of an electron and a positron results in formation of two γ rays. In the process, their masses are converted completely into energy.

(a) Calculate the energy evolved from the annihilation of an electron and a positron, in kilojoules per mole.
(b) Using Planck's equation (Equation 6.2), determine the frequency of the γ rays emitted in this process.

63. The principle underlying the isotope dilution method of analysis can be applied to many kinds of problems. Suppose that you, a marine biologist, want to estimate the number of fish in a lake. You release 1000 tagged fish, and after allowing an adequate amount of time for the fish to disperse evenly in the lake, you catch 5250 fish and find that 27 of them have tags. How many fish are in the lake?

64. ▲ Radioactive isotopes are often used as "tracers" to follow an atom through a chemical reaction. The following is an example of this process: Acetic acid reacts with methanol, CH_3OH, by eliminating a molecule of H_2O to form methyl acetate, $CH_3CO_2CH_3$. Explain how you would use the radioactive isotope ^{15}O to show whether the oxygen atom in the water product comes from the —OH of the acid or the —OH of the alcohol.

65. ▲ Radioactive decay series begin with a very long-lived isotope. For example, the half-life of ^{238}U is 4.5×10^9 years. Each series is identified by the name of the long-lived parent isotope of highest mass.

(a) The uranium-238 radioactive decay series is sometimes referred to as the $4n + 2$ series because the masses of all 13 members of this series can be expressed by the equation $M = 4n + 2$, where M is the mass number and n is an integer. Explain why the masses are correlated in this way.
(b) Two other radioactive decay series identified in minerals in the Earth's crust are the thorium-232 series and the uranium-235 series. Do the masses of the isotopes in these series conform to a simple mathematical equation? If so, identify the equation.
(c) Identify the radioactive decay series to which each of the following isotopes belongs: $^{226}_{88}$Ra, $^{215}_{86}$At, $^{228}_{90}$Th, $^{210}_{83}$Bi.
(d) Evaluation reveals that one series of elements, the $4n + 1$ series, is not present in the Earth's crust. Speculate why.

66. ▲ The thorium decay series includes the isotope $^{228}_{90}$Th. Determine the sequence of nuclei on going from $^{232}_{90}$Th to $^{228}_{90}$Th.

67. ▲ The last unknown element between bismuth and uranium was discovered by Lise Meitner (1878–1968) and Otto Hahn (1879–1968) in 1918. They obtained ^{231}Pa by chemical extraction of pitchblende, in which its concentration is about 1 ppm (part per million). This isotope, an α emitter, has a half-life of 3.27×10^4 years.

(a) Which radioactive decay series (the uranium-235, uranium-238, or thorium-232 series) contains ^{231}Pa as a member?
(b) Suggest a possible sequence of nuclear reactions starting with the long-lived isotope that eventually forms this isotope.
(c) What quantity of ore would be required to isolate 1.0 g of ^{231}Pa, assuming 100% yield?
(d) Write an equation for the radioactive decay process for ^{231}Pa.

68. ▲ You might wonder how it is possible to determine the half-life of long-lived radioactive isotopes such as ^{238}U. With a half-life of more than 10^9 years, the radioactivity of a sample of uranium will not measurably change in your lifetime. In fact, you can calculate the half-life using the mathematics governing first-order reactions.

It can be shown that a 1.0-mg sample of ^{238}U decays at the rate of 12 α emissions per second. Set up a mathematical equation for the rate of decay, $\Delta N/\Delta t = -kN$, where N is the number of nuclei in the 1.0-mg sample and $\Delta N/\Delta t$ is 12 dps. Solve this equation for the rate constant for this process, and then relate the rate constant to the half-life of the reaction. Carry out this calculation, and compare your result with the literature value, 4.5×10^9 years.

69. ▲ Marie and Pierre Curie isolated radium and polonium from uranium ore (pitchblende, which contains ^{238}U and ^{235}U). Which of the following isotopes of radium and polonium can be found in the uranium ore? (*Hint:* Consider both the isotope half-lives and the decay series starting with ^{238}U and ^{235}U.)

Isotope	Half-Life
^{226}Ra	1620 y
^{225}Ra	14.8 d
^{228}Ra	6.7 y
^{216}Po	0.15 s
^{210}Po	138.4 d

APPENDIX A

Using Logarithms and Solving Quadratic Equations

An introductory chemistry course requires basic algebra plus a knowledge of (1) exponential (or scientific) notation, (2) logarithms, and (3) quadratic equations. The use of exponential notation was reviewed on pages 32–33, and this appendix reviews the last two topics.

A-1 Logarithms

Two types of logarithms are used in this text: (1) common logarithms (abbreviated log) whose base is 10 and (2) natural logarithms (abbreviated ln) whose base is e (= 2.71828):

$$\log x = n, \text{ where } x = 10^n$$
$$\ln x = m, \text{ where } x = e^m$$

Most equations in chemistry and physics were developed in natural, or base e, logarithms, and we follow this practice in this text. The relation between log and ln is

$$\ln x = 2.303 \log x$$

Despite the different bases of the two logarithms, they are used in the same manner. What follows is largely a description of the use of common logarithms.

A common logarithm is the power to which you must raise 10 to obtain the number. For example, the log of 100 is 2, since you must raise 10 to the second power to obtain 100. Other examples are

$$\begin{aligned} \log 1000 &= \log (10^3) = 3 \\ \log 10 &= \log (10^1) = 1 \\ \log 1 &= \log (10^0) = 0 \\ \log 0.1 &= \log (10^{-1}) = -1 \\ \log 0.0001 &= \log (10^{-4}) = -4 \end{aligned}$$

To obtain the common logarithm of a number other than a simple power of 10, you must resort to a log table or an electronic calculator. For example,

$$\log 2.10 = 0.322, \text{ which means that } 10^{0.322} = 2.10$$
$$\log 5.16 = 0.713, \text{ which means that } 10^{0.713} = 5.16$$
$$\log 3.125 = 0.4949, \text{ which means that } 10^{0.4949} = 3.125$$

To check this on many calculators, enter the number, and then press the "log" key. You should make sure that you understand how to use your particular calculator.

To obtain the natural logarithm ln of the numbers shown here, use a calculator having this function. Enter each number, and press "ln:"

$$\ln 2.10 = 0.742, \text{ which means that } e^{0.742} = 2.10$$
$$\ln 5.16 = 1.641, \text{ which means that } e^{1.641} = 5.16$$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

To find the common logarithm of a number greater than 10 or less than 1 with a log table, first express the number in scientific notation. Then find the log of each part of the number and add the logs. For example,

$$\begin{aligned}\log 241 &= \log (2.41 \times 10^2) = \log 2.41 + \log 10^2 \\ &= 0.382 + 2 = 2.382 \\ \log 0.00573 &= \log (5.73 \times 10^{-3}) = \log 5.73 + \log 10^{-3} \\ &= 0.758 + (-3) = -2.242\end{aligned}$$

Significant Figures and Logarithms

Notice that the mantissa has as many significant figures as the number whose log was found.

Logarithms and Nomenclature
The number to the left of the decimal in a logarithm is called the **characteristic**, and the number to the right of the decimal is the **mantissa**.

Obtaining Antilogarithms

If you are given the logarithm of a number and find the number from it, you have obtained the "antilogarithm," or "antilog," of the number. Two common procedures used by electronic calculators to do this are as follows:

PROCEDURE A	PROCEDURE B
1. Enter the value of the log or ln.	1. Enter value of the log or ln.
2. Press 2ndF.	2. Press INV.
3. Press 10^x or e^x.	3. Press log or ln x.

Make sure you can properly perform this operation on your calculator by working the following examples:

1. Find the number whose log is 5.234:
   Recall that $\log x = n$, where $x = 10^n$. In this case, $n = 5.234$. Find the value of 10^n, the antilog. In this case,
   $$10^{5.234} = 10^{0.234} \times 10^5 = 1.71 \times 10^5$$
   Notice that the characteristic (5) sets the decimal point; it is the power of 10 in the exponential form. The mantissa (0.234) gives the value of the number x, 1.71 in this case.
2. Find the number whose log is -3.456:
   $$10^{-3.456} = 10^{0.544} \times 10^{-4} = 3.50 \times 10^{-4}$$
   Notice here that -3.456 is expressed as the sum of -4 and $+0.544$.

Mathematical Operations Using Logarithms

Because logarithms are exponents, operations involving them follow the same rules used for exponents. Thus, multiplying two numbers can be done by adding logarithms:

$$\log xy = \log x + \log y$$

For example, we multiply 563 by 125 by adding their logarithms and finding the antilogarithm of the result:

$$\begin{aligned}\log 563 &= 2.751 \\ \log 125 &= \underline{2.097} \\ \log xy &= 4.848 \\ xy &= 10^{4.848} = 10^{0.848} \times 10^4 = 7.05 \times 10^4\end{aligned}$$

One number (x) can be divided by another (y) by subtraction of their logarithms:

$$\log \frac{x}{y} = \log x - \log y$$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

For example, to divide 125 by 742,

$$\begin{aligned} \log 125 &= 2.097 \\ -\log 742 &= \underline{2.870} \\ \log \frac{x}{y} &= -0.773 \end{aligned}$$

$$\frac{x}{y} = 10^{-0.773} = 10^{0.227} \times 10^{-1} = 1.68 \times 10^{-1}$$

Similarly, powers and roots of numbers can be found using logarithms.

$$\log x^y = y(\log x)$$

$$\log \sqrt[y]{x} = \log x^{1/y} = \frac{1}{y} \log x$$

As an example, find the fourth power of 5.23. We first find the log of 5.23 and then multiply it by 4. The result, 2.874, is the log of the answer. Therefore, we find the antilog of 2.874:

$$\begin{aligned} (5.23)^4 &= ? \\ \log (5.23)^4 &= 4 \log 5.23 = 4(0.719) = 2.874 \\ (5.23)^4 &= 10^{2.874} = 748 \end{aligned}$$

As another example, find the fifth root of 1.89×10^{-9}:

$$\begin{aligned} \sqrt[5]{1.89 \times 10^{-9}} &= (1.89 \times 10^{-9})^{1/5} = ? \\ \log (1.89 \times 10^{-9})^{1/5} &= \frac{1}{5} \log(1.89 \times 10^{-9}) = \frac{1}{5}(-8.724) = -1.745 \end{aligned}$$

The answer is the antilog of -1.745:

$$\left(1.89 \times 10^{-9}\right)^{1/5} = 10^{-1.745} = 1.80 \times 10^{-2}$$

A-2 Quadratic Equations

Algebraic equations of the form $ax^2 + bx + c = 0$ are called **quadratic equations**. The coefficients a, b, and c may be either positive or negative. The two roots of the equation may be found using the *quadratic formula:*

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

As an example, solve the equation $5x^2 - 3x - 2 = 0$. Here $a = 5$, $b = -3$, and $c = -2$. Therefore,

$$\begin{aligned} x &= \frac{3 \pm \sqrt{(-3)^2 - 4(5)(-2)}}{2(5)} \\ &= \frac{3 \pm \sqrt{9 - (-40)}}{10} = \frac{3 \pm \sqrt{49}}{10} = \frac{3 \pm 7}{10} \\ &= 1 \text{ and } -0.4 \end{aligned}$$

How do you know which of the two roots is the correct answer? Mathematically, both roots are possible, but in chemistry problems you have to decide in each case which root has physical significance. It is *usually* true in this course, however, that negative values are not significant.

When you have solved a quadratic expression, you should always check your values by substitution into the original equation. In the previous example, we find that $5(1)^2 - 3(1) - 2 = 0$ and that $5(-0.4)^2 - 3(-0.4) - 2 = 0$.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The most likely place you will encounter quadratic equations is in the chapters on chemical equilibria, particularly in Chapters 15 through 17. Here, you will often be faced with solving an equation such as

$$1.8 \times 10^{-4} = \frac{x^2}{0.0010 - x}$$

This equation can certainly be solved using the quadratic formula (to give $x = 3.4 \times 10^{-4}$). You may find the **method of successive approximations** to be especially convenient, however. Here we begin by making a reasonable approximation of x. This approximate value is substituted into the original equation, which is then solved to give what is hoped to be a more correct value of x. This process is repeated until the answer converges on a particular value of x—that is, until the value of x derived from two successive approximations is the same.

Step 1: First, assume that x is so small that $(0.0010 - x) \approx 0.0010$. This means that

$$x^2 = 1.8 \times 10^{-4}\ (0.0010)$$
$$x = 4.2 \times 10^{-4}\ \text{(to 2 significant figures)}$$

Step 2: Substitute the value of x from Step 1 into the denominator of the original equation, and again solve for x:

$$x^2 = 1.8 \times 10^{-4}(0.0010 - 0.00042)$$
$$x = 3.2 \times 10^{-4}$$

Step 3: Repeat Step 2 using the value of x found in that step:

$$x = \sqrt{1.8 \times 10^{-4}(0.0010 - 0.00032)} = 3.5 \times 10^{-4}$$

Step 4: Continue repeating the calculation, using the value of x found in the previous step:

$$x = \sqrt{1.8 \times 10^{-4}(0.0010 - 0.00035)} = 3.4 \times 10^{-4}$$

Step 5:
$$x = \sqrt{1.8 \times 10^{-4}(0.0010 - 0.00034)} = 3.4 \times 10^{-4}$$

Here, we find that iterations after the fourth step give the same value for x, indicating that we have arrived at a valid answer (and the same one obtained from the quadratic formula).

Here are some final thoughts on using the method of successive approximations. First, in some cases the method does not work. Successive steps may give answers that are random or that diverge from the correct value. In Chapters 15 through 17, you confront quadratic equations of the form $K = x^2/(C - x)$. The method of successive approximations works as long as $K < 4C$ (assuming one begins with $x = 0$ as the first guess, that is, $K \approx x^2/C$). This is always going to be true for weak acids and bases (the topic of Chapters 16 and 17), but it may *not* be the case for problems involving gas phase equilibria (Chapter 15), where K can be quite large.

Second, values of K in the equation $K = x^2/(C - x)$ are usually known only to two significant figures. We are therefore justified in carrying out successive steps until two answers are the same to two significant figures.

Finally, we highly recommend this method of solving quadratic equations, especially those in Chapters 16 and 17. If your calculator has a memory function, successive approximations can be carried out easily and rapidly.

Some Important Physical Concepts

B-1 Matter

The tendency to maintain a constant velocity is called *inertia*. Thus, unless acted on by an unbalanced force, a body at rest remains at rest, and a body in motion remains in motion with uniform velocity. Matter is anything that exhibits inertia; the quantity of matter is its mass.

B-2 Motion

Motion is the change of position or location in space. Objects can have the following classes of motion:

- Translation occurs when the center of mass of an object changes its location. Example: a car moving on the highway.
- Rotation occurs when each point of a moving object moves in a circle about an axis through the center of mass. Examples: a spinning top, a rotating molecule.
- Vibration is a periodic distortion and then recovery of original shape. Examples: a struck tuning fork, a vibrating molecule.

B-3 Force and Weight

Force is that which changes the velocity of a body; it is defined as

$$\text{Force} = \text{mass} \times \text{acceleration}$$

The SI unit of force is the **newton**, N, whose dimensions are kilograms times meter per second squared ($kg \cdot m/s^2$). A newton is therefore the force needed to change the velocity of a mass of 1 kilogram by 1 meter per second in a time of 1 second.

Because the Earth's gravity is not the same everywhere, the weight (a force) corresponding to a given mass is not a constant. At any given spot on Earth, gravity is constant, however, and therefore weight is proportional to mass. When a balance tells us that a given sample (the "unknown") has the same weight as another sample (the "weights," as given by a scale reading or by a total of counterweights), it also tells us that the two masses are equal. The balance is therefore a valid instrument for measuring the mass of an object independently of slight variations in the force of gravity.

Table 1 Pressure Conversions

From	To	Multiply By
atmosphere	mm Hg	760 mm Hg/atm (exactly)
atmosphere	lb/in^2	14.6960 $lb/(in^2 \cdot atm)$
atmosphere	kPa	101.325 kPa/atm
bar	Pa	10^5 Pa/bar (exactly)
bar	lb/in^2	14.5038 $lb/(in^2 \cdot bar)$
mm Hg	torr	1 torr/mm Hg (exactly)

B-4 Pressure†

Pressure is force per unit area. The SI unit, called the *pascal*, Pa, is

$$1 \text{ pascal} = \frac{1 \text{ newton}}{m^2} = \frac{1 \text{ kg} \cdot m/s^2}{m^2} = \frac{1 \text{ kg}}{m \cdot s^2}$$

The International System of Units also recognizes the bar, which is 10^5 Pa and which is close to standard atmospheric pressure (Table 1).

Chemists also express pressure in terms of the heights of liquid columns, especially water and mercury. This usage is not completely satisfactory because the pressure exerted by a given column of a given liquid is not a constant but depends on the temperature (which influences the density of the liquid) and the location (which influences the magnitude of the force exerted by gravity). Such units are therefore not part of the SI, and their use is now discouraged. The older units are still used in books and journals, however, and chemists must be familiar with them.

The pressure of a liquid or a gas depends only on the depth (or height) and is exerted equally in all directions. At sea level, the pressure exerted by the Earth's atmosphere supports a column of mercury about 0.76 m (76 cm, or 760 mm) high.

One **standard atmosphere** (atm) is the pressure exerted by exactly 76 cm of mercury at 0 °C (density, 13.5951 g/cm^3) and at standard gravity, 9.80665 m/s^2. The **bar** is equivalent to 0.9869 atm. One **torr** is the pressure exerted by exactly 1 mm of mercury at 0 °C and standard gravity.

B-5 Energy and Power

The SI unit of energy is the product of the units of force and distance, or kilograms times meter per second squared ($kg \cdot m/s^2$) times meters ($\times$ m), which is $kg \cdot m^2/s^2$; this unit is called the **joule**, J. The joule is thus the work done when a force of 1 newton acts through a distance of 1 meter.

Work may also be done by moving an electric charge in an electric field. When the charge being moved is 1 coulomb (C) and the potential difference between its initial and final positions is 1 volt (V), the work is 1 joule. Thus,

$$1 \text{ joule} = 1 \text{ coulomb volt (CV)}$$

Another unit of electric work that is not part of the International System of Units but is still in use is the **electron volt**, eV, which is the work required to move an electron against a potential difference of 1 volt. (It is also the kinetic energy acquired

†See Section 10-1.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

by an electron when it is accelerated by a potential difference of 1 volt.) Because the charge on an electron is 1.602×10^{-19} C, we have

$$1 \text{ eV} = 1.602 \times 10^{-19} \text{ CV} \times \frac{1 \text{ J}}{1 \text{ CV}} = 1.602 \times 10^{-19} \text{ J}$$

If this value is multiplied by Avogadro's number, we obtain the energy involved in moving 1 mol of electron charges (1 faraday) in a field produced by a potential difference of 1 volt:

$$1 \frac{\text{eV}}{\text{particle}} = \frac{1.602 \times 10^{-19} \text{ J}}{\text{particle}} \times \frac{6.022 \times 10^{23} \text{ particles}}{\text{mol}} \cdot \frac{1 \text{ kJ}}{1000 \text{ J}} = 96.49 \text{ kJ/mol}$$

Power is the amount of energy delivered per unit time. The SI unit is the watt, W, which is 1 joule per second. One kilowatt, kW, is 1000 W. Watt-hours and kilowatt-hours are therefore units of energy (Table 2). For example, 1000 watt-hours, or 1 kilowatt-hour, is

$$1.0 \times 10^3 \text{ W} \cdot \text{h} \times \frac{1 \text{ J}}{1 \text{ W} \cdot \text{s}} \times \frac{3.6 \times 10^3 \text{ s}}{1 \text{ h}} = 3.6 \times 10^6 \text{ J}$$

C-1 Fundamental Units of the SI System

The metric system was begun by the French National Assembly in 1790 and has undergone many modifications. The International System of Units or *Système International* (SI), which represents an extension of the metric system, was adopted by the 11th General Conference of Weights and Measures in 1960. It is constructed from seven base units, each of which represents a particular physical quantity (Table 4).

Table 4 SI Fundamental Units

Physical Quantity	Name of Unit	Symbol
Length	meter	m
Mass	kilogram	kg
Time	second	s
Temperature	kelvin	K
Amount of substance	mole	mol
Electric current	ampere	A
Luminous intensity	candela	cd

The first five units listed in Table 4 are particularly useful in general chemistry and are defined as follows:

1. The *meter* was redefined in 1960 to be equal to 1,650,763.73 wavelengths of a certain line in the emission spectrum of krypton-86.
2. The *kilogram* represents the mass of a platinum–iridium block kept at the International Bureau of Weights and Measures at Sèvres, France.
3. The *second* was redefined in 1967 as the duration of 9,192,631,770 periods of a certain line in the microwave spectrum of cesium-133.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

4. The *kelvin* is 1/273.16 of the temperature interval between absolute zero and the triple point of water.
5. The *mole* is the amount of substance that contains as many entities as there are atoms in exactly 0.012 kg of carbon-12 (12 g of ^{12}C atoms).

C-2 Prefixes Used with Traditional Metric Units and SI Units

Decimal fractions and multiples of metric and SI units are designated by using the prefixes listed in Table 5. Those most commonly used in general chemistry appear in italics.

Table 5 Traditional Metric and SI Prefixes

Factor	Prefix	Symbol	Factor	Prefix	Symbol
10^{12}	tera	T	10^{-1}	*deci*	d
10^{9}	giga	G	10^{-2}	*centi*	c
10^{6}	mega	M	10^{-3}	*milli*	m
10^{3}	*kilo*	k	10^{-6}	micro	μ
10^{2}	hecto	h	10^{-9}	*nano*	n
10^{1}	deka	da	10^{-12}	*pico*	p
			10^{-15}	femto	f
			10^{-18}	atto	a

C-3 Derived SI Units

In the International System of Units, all physical quantities are represented by appropriate combinations of the base units listed in Table 4. A list of the derived units frequently used in general chemistry is given in Table 6.

Table 6 Derived SI Units

Physical Quantity	Name of Unit	Symbol	Definition
Area	square meter	m^2	
Volume	cubic meter	m^3	
Density	kilogram per cubic meter	kg/m^3	
Force	newton	N	$kg \cdot m/s^2$
Pressure	pascal	Pa	N/m^2
Energy	joule	J	$kg \cdot m^2/s^2$
Electric charge	coulomb	C	$A \cdot s$
Electric potential difference	volt	V	$J/(A \cdot s)$

A Brief Guide to Naming Organic Compounds

It seems a daunting task to devise a systematic procedure that gives each organic compound a unique name, but that is what has been done. A set of rules was developed to name organic compounds by the International Union of Pure and Applied Chemistry (IUPAC). The IUPAC nomenclature allows chemists to write a name for any compound based on its structure or to identify the formula and structure for a compound from its name. In this book, we have generally used the IUPAC nomenclature scheme when naming compounds.

In addition to the systematic names, many compounds have common names. The common names came into existence before the nomenclature rules were developed, and they have continued in use. For some compounds, these names are so well entrenched that they are used most of the time. One such compound is acetic acid, which is almost always referred to by that name and not by its systematic name, ethanoic acid.

The general procedure for systematic naming of organic compounds begins with the nomenclature for hydrocarbons. Other organic compounds are then named as derivatives of hydrocarbons. Nomenclature rules for simple organic compounds are given in the following section.

E-1 Hydrocarbons

Alkanes

The names of alkanes end in "-ane." When naming a specific alkane, the root of the name identifies the longest carbon chain in the compound. Specific substituent groups attached to this carbon chain are identified by name and position.

Alkanes with chains of one to ten carbon atoms are given in Table 23.2. After the first four compounds, the names derive from Greek and Latin numbers—pentane, hexane, heptane, octane, nonane, decane—and this regular naming continues for higher alkanes. For substituted alkanes, the substituent groups on a hydrocarbon chain must be identified both by a name and by the position of substitution; this information precedes the root of the name. The position is indicated by a number that refers to the carbon atom to which the substituent is attached. (Numbering of the carbon atoms in a chain should begin at the end of the carbon chain that allows the substituent groups to have the lowest numbers.)

Names of hydrocarbon substituents are derived from the name of the hydrocarbon. The group $—CH_3$, derived by taking a hydrogen from methane, is called the *methyl group;* the $—C_2H_5$ group is the *ethyl group*. The nomenclature scheme is easily extended to derivatives of hydrocarbons with other substituent groups such as —Cl (chloro), $—NO_2$ (nitro), —CN (cyano), —D (deuterio), and so on (Table 13). If two or more of the same substituent groups occur, the prefixes "di-," "tri-," and "tetra-" are added. When different substituent groups are present, they are generally listed in alphabetical order.

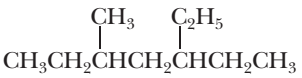
Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Table 13 Names of Common Substituent Groups

Formula	Name	Formula	Name
—CH_3	methyl	—D	deuterio
—C_2H_5	ethyl	—Cl	chloro
—$CH_2CH_2CH_3$	propyl (*n*-propyl)	—Br	bromo
—$CH(CH_3)_2$	1-methylethyl (isopropyl)	—F	fluoro
—$CH{=}CH_2$	ethenyl (vinyl)	—CN	cyano
—C_6H_5	phenyl	—NO_2	nitro
—OH	hydroxo		
—NH_2	amino		

Example:



Step	Information to Include	Contribution to Name
1	An alkane	Name will end in "-ane"
2	Longest chain is 7 carbons	Name as a *heptane*
3	—CH_3 group at carbon 3	3-*methyl*
4	—C_2H_5 group at carbon 5	5-*ethyl*
Name:	5-ethyl-3-methylheptane	

Cycloalkanes are named based on the ring size and by adding the prefix "cyclo"; for example, the cycloalkane with a six-member ring of carbons is called *cyclohexane*.

Alkenes

Alkenes have names ending in "-ene." The name of an alkene must specify the length of the carbon chain and the position of the double bond (and when appropriate, the configuration, either *cis* or *trans*). As with alkanes, both identity and position of substituent groups must be given. The carbon chain is numbered from the end that gives the double bond the lowest number.

Compounds with two double bonds are called *dienes*, and they are named similarly—specifying the positions of the double bonds and the name and position of any substituent groups.

For example, the compound $H_2C{=}C(CH_3)CH(CH_3)CH_2CH_3$ has a five-carbon chain with a double bond between carbon atoms 1 and 2 and methyl groups on carbon atoms 2 and 3. Its name using IUPAC nomenclature is **2,3-dimethyl-1-pentene**. The compound $CH_3CH{=}CHCCl_3$ with a *cis* configuration around the double bond is named **1,1,1-trichloro-*cis*-2-butene**. The compound $H_2C{=}C(Cl)CH{=}CH_2$ is **2-chloro-1,3-butadiene**.

Alkynes

The naming of alkynes is similar to the naming of alkenes, except that *cis–trans* isomerism isn't a factor. The ending "-yne" on a name identifies a compound as an alkyne.

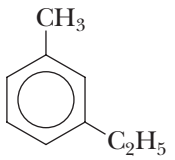
Benzene Derivatives

The carbon atoms in the six-member ring are numbered 1 through 6, and the name and position of substituent groups are given. The two examples shown here are **1-ethyl-3-methylbenzene** and **1,4-diaminobenzene**.



1-ethyl-3-methylbenzene

1,4-diaminobenzene

E-2 Derivatives of Hydrocarbons

The names for alcohols, aldehydes, ketones, and acids are based on the name of the hydrocarbon with an appropriate suffix to denote the class of compound, as follows:

- **Alcohols:** Substitute "-ol" for the final "-e" in the name of the hydrocarbon, and designate the position of the —OH group by the number of the carbon atom. For example, $CH_3CH_2CHOHCH_3$ is named as a derivative of the 4-carbon hydrocarbon butane. The —OH group is attached to the second carbon, so the name is **2-butanol**.
- **Aldehydes:** Substitute "-al" for the final "-e" in the name of the hydrocarbon. The carbon atom of an aldehyde is, by definition, carbon-1 in the hydrocarbon chain. For example, the compound $CH_3CH(CH_3)CH_2CH_2CHO$ contains a 5-carbon chain with the aldehyde functional group being carbon-1 and the $—CH_3$ group at position 4; thus, the name is **4-methylpentanal**.
- **Ketones:** Substitute "-one" for the final "-e" in the name of the hydrocarbon. The position of the ketone functional group (the carbonyl group) is indicated by the number of the carbon atom. For example, the compound $CH_3COCH_2CH(C_2H_5)CH_2CH_3$ has the carbonyl group at the 2 position and an ethyl group at the 4 position of a 6-carbon chain; its name is **4-ethyl-2-hexanone**.
- **Carboxylic acids (organic acids):** Substitute "-oic" for the final "-e" in the name of the hydrocarbon. The carbon atoms in the longest chain are counted beginning with the carboxylic carbon atom. For example, *trans*-$CH_3CH{=}CHCH_2CO_2H$ is named as a derivative of *trans*-3-pentene—that is, ***trans*-3-pentenoic acid**.

An **ester** is named as a derivative of the alcohol and acid from which it is made. The name of an ester is obtained by splitting the formula RCO_2R' into two parts, the $RCO_2—$ portion and the —R′ portion. The —R′ portion comes from the alcohol and is identified by the hydrocarbon group name; derivatives of ethanol, for example, are called *ethyl* esters. The acid part of the compound is named by dropping the "-oic" ending for the acid and replacing it by "-oate." The compound $CH_3CH_2CO_2CH_3$ is named **methyl propanoate**.

Notice that an anion derived from a carboxylic acid by loss of the acidic proton is named the same way. Thus, $CH_3CH_2CO_2^-$ is the **propanoate anion**, and the sodium salt of this anion, $Na(CH_3CH_2CO_2)$, is **sodium propanoate**.

Ionization Constants for Aqueous Weak Acids at 25 °C

Table 16 Ionization Constants for Aqueous Weak Acids at 25 °C

Acid	Formula and Ionization Equation	K_a
Acetic	$CH_3CO_2H \rightleftharpoons H^+ + CH_3CO_2^-$	1.8×10^{-5}
Arsenic	$H_3AsO_4 \rightleftharpoons H^+ + H_2AsO_4^-$ $H_2AsO_4^- \rightleftharpoons H^+ + HAsO_4^{2-}$ $HAsO_4^{2-} \rightleftharpoons H^+ + AsO_4^{3-}$	$K_1 = 5.8 \times 10^{-3}$ $K_2 = 1.1 \times 10^{-7}$ $K_3 = 3.2 \times 10^{-12}$
Arsenous	$H_3AsO_3 \rightleftharpoons H^+ + H_2AsO_3^-$ $H_2AsO_3^- \rightleftharpoons H^+ + HAsO_3^{2-}$	$K_1 = 6.0 \times 10^{-10}$ $K_2 = 3.0 \times 10^{-14}$
Benzoic	$C_6H_5CO_2H \rightleftharpoons H^+ + C_6H_5CO_2^-$	6.3×10^{-5}
Boric	$H_3BO_3 \rightleftharpoons H^+ + H_2BO_3^-$ $H_2BO_3^- \rightleftharpoons H^+ + HBO_3^{2-}$ $HBO_3^{2-} \rightleftharpoons H^+ + BO_3^{3-}$	$K_1 = 7.3 \times 10^{-10}$ $K_2 = 1.8 \times 10^{-13}$ $K_3 = 1.6 \times 10^{-14}$
Carbonic	$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$ $HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$	$K_1 = 4.2 \times 10^{-7}$ $K_2 = 4.8 \times 10^{-11}$
Citric	$H_3C_6H_5O_7 \rightleftharpoons H^+ + H_2C_6H_5O_7^-$ $H_2C_6H_5O_7^- \rightleftharpoons H^+ + HC_6H_5O_7^{2-}$ $HC_6H_5O_7^{2-} \rightleftharpoons H^+ + C_6H_5O_7^{3-}$	$K_1 = 7.4 \times 10^{-3}$ $K_2 = 1.7 \times 10^{-5}$ $K_3 = 4.0 \times 10^{-7}$
Cyanic	$HOCN \rightleftharpoons H^+ + OCN^-$	3.5×10^{-4}
Formic	$HCO_2H \rightleftharpoons H^+ + HCO_2^-$	1.8×10^{-4}
Hydrazoic	$HN_3 \rightleftharpoons H^+ + N_3^-$	1.9×10^{-5}
Hydrocyanic	$HCN \rightleftharpoons H^+ + CN^-$	4.0×10^{-10}
Hydrofluoric	$HF \rightleftharpoons H^+ + F^-$	7.2×10^{-4}
Hydrogen peroxide	$H_2O_2 \rightleftharpoons H^+ + HO_2^-$	2.4×10^{-12}
Hydrosulfuric	$H_2S \rightleftharpoons H^+ + HS^-$ $HS^- \rightleftharpoons H^+ + S^{2-}$	$K_1 = 1 \times 10^{-7}$ $K_2 = 1 \times 10^{-19}$
Hypobromous	$HOBr \rightleftharpoons H^+ + OBr^-$	2.5×10^{-9}
Hypochlorous	$HOCl \rightleftharpoons H^+ + OCl^-$	3.5×10^{-8}
Nitrous	$HNO_2 \rightleftharpoons H^+ + NO_2^-$	4.5×10^{-4}
Oxalic	$H_2C_2O_4 \rightleftharpoons H^+ + HC_2O_4^-$ $HC_2O_4^- \rightleftharpoons H^+ + C_2O_4^{2-}$	$K_1 = 5.9 \times 10^{-2}$ $K_2 = 6.4 \times 10^{-5}$

Ionization Constants for Aqueous Weak Bases at 25 °C

Table 17 Ionization Constants for Aqueous Weak Bases at 25 °C

Base	Formula and Ionization Equation	K_b
Ammonia	$NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$	1.8×10^{-5}
Aniline	$C_6H_5NH_2 + H_2O \rightleftharpoons C_6H_5NH_3^+ + OH^-$	4.0×10^{-10}
Dimethylamine	$(CH_3)_2NH + H_2O \rightleftharpoons (CH_3)_2NH_2^+ + OH^-$	7.4×10^{-4}
Ethylamine	$C_2H_5NH_2 + H_2O \rightleftharpoons C_2H_5NH_3^+ + OH^-$	4.3×10^{-4}
Ethylenediamine	$H_2NCH_2CH_2NH_2 + H_2O \rightleftharpoons H_2NCH_2CH_2NH_3^+ + OH^-$ $H_2NCH_2CH_2NH_3^+ + H_2O \rightleftharpoons H_3NCH_2CH_2NH_3^{2+} + OH^-$	$K_1 = 8.5 \times 10^{-5}$ $K_2 = 2.7 \times 10^{-8}$
Hydrazine	$N_2H_4 + H_2O \rightleftharpoons N_2H_5^+ + OH^-$ $N_2H_5^+ + H_2O \rightleftharpoons N_2H_6^{2+} + OH^-$	$K_1 = 8.5 \times 10^{-7}$ $K_2 = 8.9 \times 10^{-16}$
Hydroxylamine	$NH_2OH + H_2O \rightleftharpoons NH_3OH^+ + OH^-$	6.6×10^{-9}
Methylamine	$CH_3NH_2 + H_2O \rightleftharpoons CH_3NH_3^+ + OH^-$	5.0×10^{-4}
Pyridine	$C_5H_5N + H_2O \rightleftharpoons C_5H_5NH^+ + OH^-$	1.5×10^{-9}
Trimethylamine	$(CH_3)_3N + H_2O \rightleftharpoons (CH_3)_3NH^+ + OH^-$	7.4×10^{-5}

Solubility Product Constants for Some Inorganic Compounds at 25 °C

Table 18A Solubility Product Constants at 25 °C

Cation	Compound	K_{sp}	Cation	Compound	K_{sp}
Ba^{2+}	*$BaCrO_4$	1.2×10^{-10}	Hg_2^{2+}	*Hg_2Br_2	6.4×10^{-23}
	$BaCO_3$	2.6×10^{-9}		Hg_2Cl_2	1.4×10^{-18}
	BaF_2	1.8×10^{-7}		*Hg_2I_2	2.9×10^{-29}
	*$BaSO_4$	1.1×10^{-10}		Hg_2SO_4	6.5×10^{-7}
Ca^{2+}	$CaCO_3$ (calcite)	3.4×10^{-9}	Ni^{2+}	$NiCO_3$	1.4×10^{-7}
	*CaF_2	5.3×10^{-11}		$Ni(OH)_2$	5.5×10^{-16}
	*$Ca(OH)_2$	5.5×10^{-5}	Ag^+	*$AgBr$	5.4×10^{-13}
	$CaSO_4$	4.9×10^{-5}		*$AgBrO_3$	5.4×10^{-5}
Cu^+, Cu^{2+}	$CuBr$	6.3×10^{-9}		$AgCH_3CO_2$	1.9×10^{-3}
	CuI	1.3×10^{-12}		$AgCN$	6.0×10^{-17}
	$Cu(OH)_2$	2.2×10^{-20}		Ag_2CO_3	8.5×10^{-12}
	$CuSCN$	1.8×10^{-13}		*$Ag_2C_2O_4$	5.4×10^{-12}
Au^+	$AuCl$	2.0×10^{-13}		*$AgCl$	1.8×10^{-10}
				Ag_2CrO_4	1.1×10^{-12}
Fe^{2+}	$FeCO_3$	3.1×10^{-11}		*AgI	8.5×10^{-17}
	$Fe(OH)_2$	4.9×10^{-17}		$AgSCN$	1.0×10^{-12}
				*Ag_2SO_4	1.2×10^{-5}
Pb^{2+}	$PbBr_2$	6.6×10^{-6}	Sr^{2+}	$SrCO_3$	5.6×10^{-10}
	$PbCO_3$	7.4×10^{-14}		SrF_2	4.3×10^{-9}
	$PbCl_2$	1.7×10^{-5}		$SrSO_4$	3.4×10^{-7}
	$PbCrO_4$	2.8×10^{-13}			
	PbF_2	3.3×10^{-8}	Tl^+	$TlBr$	3.7×10^{-6}
	PbI_2	9.8×10^{-9}		$TlCl$	1.9×10^{-4}
	$Pb(OH)_2$	1.4×10^{-15}		TlI	5.5×10^{-8}
	$PbSO_4$	2.5×10^{-8}			
			Zn^{2+}	$Zn(OH)_2$	3×10^{-17}
Mg^{2+}	$MgCO_3$	6.8×10^{-6}		$Zn(CN)_2$	8.0×10^{-12}
	MgF_2	5.2×10^{-11}			
	$Mg(OH)_2$	5.6×10^{-12}			
Mn^{2+}	$MnCO_3$	2.3×10^{-11}			
	*$Mn(OH)_2$	1.9×10^{-13}			

The values reported in this table were taken from J. A. Dean: *Lange's Handbook of Chemistry,* 15th ed. New York: McGraw-Hill Publishers, 1999. Values have been rounded off to two significant figures.

*Calculated solubility from these K_{sp} values will match experimental solubility for this compound within a factor of 2. Experimental values for solubilities are given in R. W. Clark and J. M. Bonicamp: *Journal of Chemical Education,* Vol. 75, p. 1182, 1998.

Formation Constants for Some Complex Ions in Aqueous Solution at 25 °C

Table 19 Formation Constants for Some Complex Ions in Aqueous Solution at 25 °C*

FORMATION EQUILIBRIUM	*K*
$Ag^+ + 2\ Br^- \rightleftharpoons [AgBr_2]^-$	2.1×10^7
$Ag^+ + 2\ Cl^- \rightleftharpoons [AgCl_2]^-$	1.1×10^5
$Ag^+ + 2\ CN^- \rightleftharpoons [Ag(CN)_2]^-$	1.3×10^{21}
$Ag^+ + 2\ S_2O_3^{2-} \rightleftharpoons [Ag(S_2O_3)_2]^{3-}$	2.9×10^{13}
$Ag^+ + 2\ NH_3 \rightleftharpoons [Ag(NH_3)_2]^+$	1.1×10^7
$Al^{3+} + 6\ F^- \rightleftharpoons [AlF_6]^{3-}$	6.9×10^{19}
$Al^{3+} + 4\ OH^- \rightleftharpoons [Al(OH)_4]^-$	1.1×10^{33}
$Au^+ + 2\ CN^- \rightleftharpoons [Au(CN)_2]^-$	2.0×10^{38}
$Cd^{2+} + 4\ CN^- \rightleftharpoons [Cd(CN)_4]^{2-}$	6.0×10^{18}
$Cd^{2+} + 4\ NH_3 \rightleftharpoons [Cd(NH_3)_4]^{2+}$	1.3×10^7
$Co^{2+} + 6\ NH_3 \rightleftharpoons [Co(NH_3)_6]^{2+}$	1.3×10^5
$Cu^+ + 2\ CN^- \rightleftharpoons [Cu(CN)_2]^-$	1.0×10^{24}
$Cu^+ + 2\ Cl^- \rightleftharpoons [CuCl_2]^-$	3.2×10^5
$Cu^{2+} + 4\ NH_3 \rightleftharpoons [Cu(NH_3)_4]^{2+}$	2.1×10^{13}
$Fe^{2+} + 6\ CN^- \rightleftharpoons [Fe(CN)_6]^{4-}$	1.0×10^{35}
$Hg^{2+} + 4\ Cl^- \rightleftharpoons [HgCl_4]^{2-}$	1.2×10^{15}
$Ni^{2+} + 4\ CN^- \rightleftharpoons [Ni(CN)_4]^{2-}$	2.0×10^{31}
$Ni^{2+} + 6\ NH_3 \rightleftharpoons [Ni(NH_3)_6]^{2+}$	5.5×10^8
$Zn^{2+} + 4\ OH^- \rightleftharpoons [Zn(OH)_4]^{2-}$	4.6×10^{17}
$Zn^{2+} + 4\ NH_3 \rightleftharpoons [Zn(NH_3)_4]^{2+}$	2.9×10^9

*Data reported in this table are taken from J. A. Dean: *Lange's Handbook of Chemistry,* 15th ed. New York: McGraw-Hill Publishers, 1999.

APPENDIX N

Answers to Study Questions, Review & Check, Check Your Understanding, and Case Study Questions

Chapter 1 and Chapter 1-LR

Case Study

CO_2 in the Oceans

1. Carbon dioxide
2. Calcium: Ca; copper: Cu; manganese: Mn; iron: Fe
3. Most dense: copper, least dense: calcium
4. Elements: calcium, carbon, oxygen
   Compound name: calcium carbonate

Review & Check

Section 1-3

1. (a) dry ice (solid CO_2)
2. (c) Can be separated into two other pure substances by physical means.

Section 1-4

1. (b) Na
2. (d) silicon

Section 1-5

1. (d) water
2. (c) potassium

Section 1-6

1. (c) gasoline burns in air
2. (b) polypropylene < water < soda bottle plastic
3. (d) volume = 13.6 cm^3

Section 1-7

1. (b) The campfire wood burns.

Section 1-8

1. (d) 1.0 g of water vapor at 100 °C
2. (a) A mixture of H_2 and O_2 has lower chemical potential energy than H_2O.

Study Questions

1.1
(a) C, carbon
(b) K, potassium
(c) Cl, chlorine
(d) P, phosphorus
(e) Mg, magnesium
(f) Ni, nickel

1.3
(a) Ba, barium
(b) Ti, titanium
(c) Cr, chromium
(d) Pb, lead
(e) As, arsenic
(f) Zn, zinc

1.5
(a) Na (element) and NaCl (compound)
(b) Sugar (compound) and carbon (element)
(c) Gold (element) and gold chloride (compound)

1.7
(a) Physical property
(b) Chemical property
(c) Chemical property
(d) Physical property
(e) Physical property
(f) Physical property

1.9
(a) Physical (colorless liquid) and chemical (burns in air)
(b) Physical (shiny metal, orange-red) and chemical (reacts with bromine)

1.11 Mechanical energy is used to move the lever, which in turn moves gears. The device produces electrical energy and radiant energy.

1.13 (a) Kinetic energy
(b) Potential energy
(c) Potential energy
(d) Potential energy

1.15 (a) Qualitative: blue-green color, solid physical state
Quantitative: density = 2.65 g/cm^3 and mass = 2.5 g
(b) Density, physical state, and color are intensive properties, whereas mass is an extensive property.
(c) Volume = 0.94 cm^3

1.17 Observation c is a chemical property.

1.19 Calcium, Ca; fluorine, F

The crystals are cubic in shape because the atoms are arranged in cubic structures.

1.21 The water can be removed by boiling the solution until all of the water evaporates. The solid that remains is salt, NaCl.

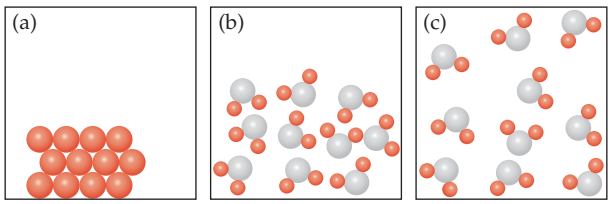
1.23 Physical changes: a, b, d
Chemical changes: c

1.25 The macroscopic view is the photograph of NaCl, and the particulate view is the drawing of the ions in a cubic arrangement. The structure of the compound at the particulate level determines the properties that are observed at the macroscopic level.

1.27 The density of the plastic is less than that of CCl_4, so the plastic will float on the liquid CCl_4. Aluminum is more dense than CCl_4, so aluminum will sink when placed in CCl_4.

1.29 (a) Mixture
(b) Mixture
(c) Element
(d) Compound

1.31



1.33 The three liquids will form three separate layers with hexane on the top, water in the middle, and perfluorohexane on the bottom. The HDPE will float at the interface of the hexane and water layers. The PVC will float at the interface of the water and perfluorohexane layers. The Teflon will sink to the bottom of the cylinder.

1.35 HDPE will float in ethylene glycol, water, acetic acid, and glycerol.

1.37 Milk is mostly water. When water freezes its density decreases, so for a given mass of water, the volume increases considerably. The increased volume means that the frozen water expands out of the bottle.

1.39 If too much sugar is excreted, the density of the urine would be higher than normal. If too much water is excreted, the density would be lower than normal.

1.41 (a) Solid potassium metal reacts with liquid water to produce gaseous hydrogen and a homogeneous mixture (solution) of potassium hydroxide in liquid water.
(b) The reaction is a chemical change.
(c) The reactants are potassium and water. The products are hydrogen gas and a water (aqueous) solution of potassium hydroxide. Heat and light are also evolved.
(d) Among the qualitative observations are (i) the reaction is violent, and (ii) heat and light (a purple flame) are produced.

1.43 The balloons containing helium and neon will float in air.

1.45 Physical change

1.47 (a) Gold = Au, silver = Ag, and copper = Cu
(b) T (K) = (1 K/1 °C)(1064 °C + 273 °C) = 1337 K
(c) No, gold is not the most dense element. Iridium Ir, is slightly more dense (22.65 g/cm^3).
(d) Mass gold = 0.75 × 5.58 g = 4.2 g
(e) Mass loss = (6.15 mg/ring)(1 g/1000 mg) (5.6 × 10^7 rings) = 3.4 × 10^5 g
Value lost = (3.4 × 10^5 g)(1 troy oz/31.1 g) ($1620/1 troy oz) = $1.8 × 10^7 (or 18 million dollars)

Case Study

Out of Gas!

1. Fuel density in kg/L: (1.77 lb/L) (0.4536 kg/lb) = 0.803 kg/L

2. Mass of fuel already in tank: 7682 L (0.803 kg/L) = 6170 kg

   Mass of fuel needed: 22,300 kg − 6,170 kg = 16,100 kg (answer to three significant figures)

   Volume of fuel needed: 16,130 kg (1 L/0.803 kg) = 20,100 L

Check Your Understanding

LR-1. 0.154 nm (1 m/10^9 nm)(10^{12} pm/1 m) = 154 pm

0.154 nm (1 m/10^9 nm)(100 cm/1 m) = 1.54 × 10^{-8} cm

LR-2. Student A: average = 5.4 °C;
percent error = [0.1/278.65] × 100% = 0.04%

Student B: average = 5.51 °C;
percent error = [0.01/278.65] × 100% = 0.004%

Student B has the smaller error.

LR-3. $x = 3.9 \times 10^5$. The difference between 110.7 and 64 is 47. Dividing 47 by 0.056 and 0.00216 gives an answer with two significant figures.

LR-4. (19,320 kg/m^3)(10^3 g/1 kg)(1 m^3/10^6 cm^3) = 19.32 g/cm^3

LR-5. Change all dimensions to centimeters: 7.6 m = 760 cm; 2.74 m = 274 cm; 0.13 mm = 0.013 cm.

Volume of paint = (760 cm)(274 cm)(0.013 cm) = 2.7×10^3 cm^3

Volume (L) = (2.7×10^3 cm^3)(1 L/10^3 cm^3) = 2.7 L

Mass = (2.7×10^3 cm^3)(0.914 g/cm^3) = 2.5×10^3 g

Review & Check

Section 1

1. (b) −196 °C

2. (c) 0.16 cm^3

3. (a) 0.750 L

4. (c) 1.9 L

5. (a) 5.59×10^3 mg

6. (d) 2×10^{-8} g/L

7. (c) 1050 kJ

Section 2

1. (c) 0.03 g

2. (b) Student B

Section 3

1. (c) 3

2. (a) 1

3. (b) 10.32 g

4. (c) 0.65 cm^2

Section 4

1. (a) 23.3 km^2

Section 5

1. (a) 2.4

2. (d) 78 g

Section 6

1. (c) 130 m

Study Questions

1. 298 K

3. (a) 289 K
(b) 97 °C
(c) 310 K (3.1×10^2 K)

5. 42,195 m; 26.219 miles

7. 5.3 cm^2; 5.3×10^{-4} m^2

9. 250. cm^3; 0.250 L, 2.50×10^{-4} m^3; 0.250 dm^3

11. 2.52×10^3 g

13. 555 g

15. (c) zinc

17. 5.0×10^6 J

19. 170 kcal is equivalent to 710 kJ, which is considerably greater than 280 kJ.

21. (a) Method A with all data included: average = 2.4 g/cm^3

Method B with all data included: average = 3.480 g/cm^3

For B, the 5.811 g/cm^3 data point can be excluded because it is more than twice as large as all other points for Method B. Using only the first three points, average = 2.703 g/cm^3

(b) Method A: error = 0.3 g/cm^3 or about 10%

Method B: error = 0.001 g/cm^3 or about 0.04%

(c) Method A: standard deviation = 0.2 g/cm^3

Method B (including all data points): standard deviation = 1.554 g/cm^3

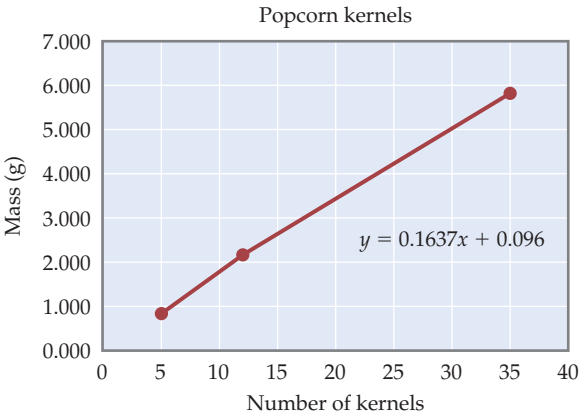
Method B (excluding the 5.811 g/cm^3 data point): standard deviation = 0.002 g/cm^3

(d) Method B's average value is both more precise and more accurate so long as the 5.811 g/cm^3 data point is excluded.

23. (a) 5.4×10^{-2} g, two significant figures
(b) 5.462×10^3 g, four significant figures
(c) 7.92×10^{-4} g, three significant figures
(d) 1.6×10^3 mL, two significant figures

25. (a) 9.44×10^{-3}
(b) 5694
(c) 11.9
(d) 0.122

27.



Slope: 0.1637 g/kernel

The slope represents the average mass of a popcorn kernel.

Mass of 20 popcorn kernels = 3.370 g

There are 127 kernels in a sample with a mass of 20.88 g.

29. (a) y = −4.00x + 20.00
(b) y = −4.00

31. C = 0.0823

33. T = 295

35. 0.197 nm; 197 pm

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

37. (a) 7.5×10^{-6} m; (b) 7.5×10^{3} nm; (c) 7.5×10^{6} pm

39. 50. mg procaine hydrochloride

41. The volume of the marbles is 99 mL − 61 mL = 38 mL. This yields a density of 2.5 g/cm^3.

43. (a) 0.178 nm^3; 1.78×10^{-22} cm^3
(b) 3.87×10^{-22} g
(c) 9.68×10^{-23} g

45. Your normal body temperature (about 98.6 °F) is 37 °C. As this is higher than gallium's melting point, the metal will melt in your hand.

47. (a) 15%
(b) 3.63×10^{3} kernels

49. 8.0×10^{4} kg of sodium fluoride per year

51. 245 g sulfuric acid

53. (a) 272 mL ice
(b) The ice cannot be contained in the can.

55. 7.99 g/cm^3

57. (a) 8.7 g/cm^3
(b) The metal is probably cadmium, but the calculated density is close to that of cobalt, nickel, and copper. Further testing should be done on the metal.

59. 0.0927 cm

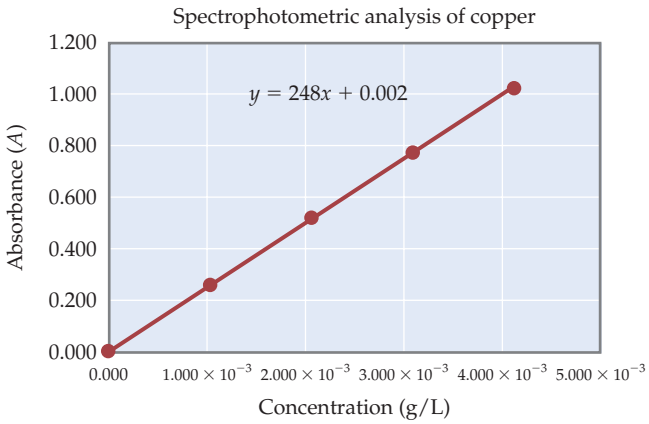
61. (a) 1.143×10^{21} atoms; 76.4% of the lattice is filled with atoms; 23.6% of the lattice is open space.

Atoms are spheres. When spheres are packed together, they touch only at certain points, therefore leaving spaces in the structure.

(b) Four atoms

63. Al, aluminum

65.



When absorbance = 0.635, concentration = 2.55×10^{-3} g/L = 2.55×10^{-3} mg/mL

67. Average = 5.24%, standard deviation = 0.05%

Seven of the ten values fall within the region $5.19 \leq x \leq 5.29$

Chapter 2

Case Studies

Using Isotopes: Ötzi, the Iceman of the Alps

1. ^{18}O: 18 − 8 = 10 neutrons
^{204}Pb: 204 − 82 = 122 neutrons
^{206}Pb: 206 − 82 = 124 neutrons

2. 15.9993 u

Arsenic, Medicine, and the Formula of Compound 606

1. Amount As: 19.024 g As × (1 mol As/74.9216 g As) = 0.25392 mol As

Amount Cu: 48.407 g Cu × (1 mol Cu/63.546 g Cu) = 0.76176 mol Cu

Amount S: 32.569 g S × (1 mol S/32.066 g S) = 1.0157 mol S

Mole ratio Cu/As: 0.76176 mol Cu/0.25392 mol As = 3.0000 mol Cu/1 mol As

Mole ratio S/As: 1.0157 mol S/0.25392 mol As = 4.0001 mol S/1 mol As

Empirical formula: Cu_3AsS_4

2. Amount C: 39.37 g C × (1 mol C/12.011 g C) = 3.278 mol C

Amount H: 3.304 g H × (1 mol H/1.0079 g H) = 3.278 mol H

Amount O: 8.741 g O × (1 mol O/15.999 g O) = 0.5463 mol O

Amount N: 7.652 g N × (1 mol N/14.007 g N) = 0.5463 mol N

Amount As: 40.932 g As × (1 mol As/74.9216 g As) = 0.54633 mol As

Mole ratio C/O and H/O: 3.278 mol C/0.5463 mol O = 6.000 mol C/1 mol O. A similar calculation yields 6.000 mol H/1 mol O.

Mole ratio N/O and As/O: 0.5463 mol N/0.5463 mol O = 1.000 mol N/1 mol O. A similar calculation yields 1.000 mol As/1 mol O.

Empirical formula: C_6H_6AsNO

Molar mass of C_6H_6AsNO: 183.0 g/mol

Compound 1: 549/183.0 = 3.00; therefore, the molecular formula is $C_{18}H_{18}As_3N_3O_3$.

Compound 2: 915/183.0 = 5.00; therefore, the molecular formula is $C_{30}H_{30}As_5N_5O_5$.

Check Your Understanding

2.1 (1) Mass number with 26 protons and 30 neutrons is 56
(2) (59.930788 u)(1.661 × 10^{-24} g/u) = 9.955×10^{-23} g
(3) ^{64}Zn has 30 protons, 30 electrons, and (64 − 30) = 34 neutrons.

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

2.2 Use Equation 2.2 for the calculation.

Atomic mass = (34.96885)(75.77/100) + (36.96590)(24.23/100) = 35.45. (Accuracy is limited by the value of the percent abundance to four significant figures.)

2.3 Use Equation 2.2 for the calculation. Let x = percent abundance of ^{20}Ne and y = percent abundance of ^{22}Ne.

20.1797 u = (x/100)(19.992435 u) + (0.27/100)(20.993843 u) + (y/100)(21.991383 u)

Because all the percent abundances must sum to 100%, $y = 100 - x - 0.27 = 99.73 - x$.

20.1797 u = (x/100)(19.992435 u) + 0.27/100) (20.993843 u) + [(99.73 − x)/100](21.991383 u)

x = 90.5; therefore the percent abundance of ^{20}Ne = 90.5% and the percent abundance of ^{22}Ne = 9.2%.

2.4 (a) (1) NaF: 1 Na^+ and 1 F^- ion. (2) $Cu(NO_3)_2$: 1 Cu^{2+} and 2 NO_3^- ions. (3) $NaCH_3CO_2$: 1 Na^+ and 1 $CH_3CO_2^-$ ion.

2.5 (a) Na_2S, Na_3PO_4, BaS, $Ba_3(PO_4)_2$
(b) $FeCl_2$, $FeCl_3$

2.6 (2.6 × 10^{24} atoms)(1 mol/6.022 × 10^{23} atoms) (197.0 g Au/1 mol) = 850 g Au

Volume = (850 g Au)(1.00 cm^3/19.32 g) = 44 cm^3

2.7 Molar mass $H_3C_6H_5O_7$ = 8(1.01) + 6(12.01) + 7(16.00) = 192.14 g/mol

(454 g $H_3C_6H_5O_7$)(1 mol $H_3C_6H_5O_7$/192.14 g $H_3C_6H_5O_7$) = 2.36 mol $H_3C_6H_5O_7$

(2.36 mol $H_3C_6H_5O_7$)(6.022 × 10^{23} molecules/1 mol) = 1.42 × 10^{24} molecules $H_3C_6H_5O_7$

(1.42 × 10^{24} molecules $H_3C_6H_5O_7$)(6 atoms C/1 molecule $H_3C_6H_5O_7$) = 8.54 × 10^{24} atoms C

2.8 (1) 1.00 mol $(NH_4)_2CO_3$ (molar mass 96.09 g/mol) has 28.0 g of N (29.1%), 8.06 g of H (8.39%), 12.0 g of C (12.5%), and 48.0 g of O (50.0%)
(2) 454 g C_8H_{18} (1 mol C_8H_{18}/114.2 g)
(8 mol C/1 mol C_8H_{18})(12.01 g C/1 mol C) = 382 g C

2.9 (1) C_5H_4

(2) $C_2H_4O_2$

(3) (88.17 g C)(1 mol C/12.011 g C) = 7.341 mol C

(11.83 g H)(1 mol H/1.008 g H) = 11.74 mol H

11.74 mol H/7.341 mol C = 1.6 mol H/1 mol C = (8/5); (mol H/1 mol C) = 8 mol H/5 mol C

The empirical formula is C_5H_8. The molar mass, 68.11 g/mol, closely matches this formula, so C_5H_8 is also the molecular formula.

(4) (78.90 g C)(1 mol C/12.011 g C) = 6.569 mol C

(10.59 g H)(1 mol H/1.008 g H) = 10.51 mol H

(10.51 g O)(1 mol O/16.00 g O) = 0.6569 mol O

10.51 mol H/0.6569 mol O = 16 mol H/1 mol O

6.569 mol C/0.6569 mol O = 10 mol C/1 mol O

The empirical formula is $C_{10}H_{16}O$.

2.10 (1.25 g Ga)(1 mol Ga/69.72 g Ga) = 0.0179 mol Ga

1.68 g product − 1.25 g Ga = 0.43 g O

(0.43 g O)(1 mol O/16.00 g O) = 0.027 mol O

Mole ratio = 0.027 mol O/0.0179 mol Ga = 1.5 mol O/1.0 mol Ga = 3.0 mol O/2.0 mol Ga

Empirical formula = Ga_2O_3

2.11 Mass of water lost on heating is 0.235 g − 0.128 g = 0.107 g; 0.128 g $NiCl_2$ remain

(0.107 g H_2O)(1 mol H_2O/18.016 g H_2O) = 0.00594 mol H_2O
(0.128 g $NiCl_2$)(1 mol $NiCl_2$/129.6 g $NiCl_2$) = 0.000988 mol $NiCl_2$

Mole ratio = 0.00594 mol H_2O/0.000988 mol $NiCl_2$ = 6.01: Therefore x = 6

The formula for the hydrate is $NiCl_2 \cdot 6\ H_2O$.

3. % Abundance ^{40}Ar = 99.600%
Atomic mass of ^{40}Ar = 39.963 u

Study Questions

2.1 Atoms contain the following fundamental particles: protons (+1 charge), neutrons (zero charge), and electrons (−1 charge). Protons and neutrons are in the nucleus of an atom. Electrons are the least massive of the three particles.

2.3 The electron cloud would extend around 1×10^{-13} cm = 1 fm.

2.5 (a) $^{27}_{12}Mg$
(b) $^{48}_{22}Ti$
(c) $^{62}_{30}Zn$

2.7

Element	Electrons	Protons	Neutrons
^{24}Mg	12	12	12
^{119}Sn	50	50	69
^{232}Th	90	90	142
^{13}C	6	6	7
^{63}Cu	29	29	34
^{205}Bi	83	83	122

2.9 mass *p*/mass *e* = 1.672622×10^{-24} g/9.109383×10^{-28} g = 1836.15. The proton is more than 1800 times heavier than the electron. Thomson's estimate was off by a factor of 2.

2.11 Gamma rays (γ) have no charge and so are unaffected by the electric field. Alpha particles (α) are positively charged and attracted to the negative plate, and beta particles (β) are negatively charged and attracted to the positive plate. Beta particles are more affected by the electric field because they are lighter than alpha particles. (Alpha particles are He^+ ions, whereas beta particles are electrons.)

2.13 $^{16}O/^{12}C$ = 1.3329

2.15 $^{57}_{27}Co$, $^{58}_{27}Co$, $^{60}_{27}Co$

2.17 Protium: one proton, one electron
Deuterium: one proton, one neutron, one electron
Tritium: one proton, two neutrons, one electron

2.19 ^{205}Tl is more abundant than ^{203}Tl. The atomic mass of thallium is closer to 205 than to 203.

2.21 (0.0750)(6.015121) + (0.9250)(7.016003) = 6.94

2.23 ^{69}Ga, 60.12%; ^{71}Ga, 39.88%

2.25

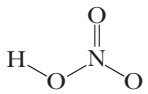
	Symbol	Atomic No.	Atomic Mass	Group	Period	
Titanium	Ti	22	47.867	4B(IUPAC 4)	4	Metal
Thallium	Tl	81	204.3833	3A(IUPAC 13)	6	Metal

2.27 Eight elements: periods 2 and 3. 18 elements: periods 4 and 5. 32 elements: periods 6 and 7.

2.29 (a) Nonmetals: C, Cl
(b) Main group elements: C, Ca, Cl, Cs
(c) Lanthanides: Ce
(d) Transition elements: Cr, Co, Cd, Ce, Cm, Cu, Cf
(e) Actinides: Cm, Cf
(f) Gases: Cl

2.31 Metals: Na, Ni, Np
Metalloids: None in this list
Nonmetals: N, Ne

2.33 Molecular formula: HNO_3.
Structural formula:



The structure around the N atom is flat. The O atoms are arranged around the N atoms at the corners of a triangle. The hydrogen atom is connected to one of the oxygen atoms.

2.35 (a) Mg^{2+}
(b) Zn^{2+}
(c) Ni^{2+}
(d) Ga^{3+}

2.37 (a) Ba^{2+}
(b) Ti^{4+}
(c) PO_4^{3-}
(d) HCO_3^-
(e) S^{2-}
(f) ClO_4^-
(g) Co^{2+}
(h) SO_4^{2-}

2.39 K loses one electron per atom to form a K^+ ion. It has the same number of electrons as an Ar atom.

2.41 Ba^{2+} and Br^- ions. The compound's formula is $BaBr_2$.

2.43 (a) Two K^+ ions and one S^{2-} ion
(b) One Co^{2+} ion and one SO_4^{2-} ion
(c) One K^+ ion and one MnO_4^- ion
(d) Three NH_4^+ ions and one PO_4^{3-} ion
(e) One Ca^{2+} ion and two ClO^- ions
(f) One Na^+ ion and one $CH_3CO_2^-$ ion

2.45 Co^{2+} gives CoO and Co^{3+} gives Co_2O_3.

2.47 (a) $AlCl_2$ should be $AlCl_3$ (based on an Al^{3+} ion and three Cl^- ions).
(b) KF_2 should be KF (based on a K^+ ion and an F^- ion).
(c) Ga_2O_3 is correct.
(d) MgS is correct.

2.49 (a) Potassium sulfide
(b) Cobalt(II) sulfate
(c) Ammonium phosphate
(d) Calcium hypochlorite

2.51 (a) $(NH_4)_2CO_3$
(b) CaI_2
(c) $CuBr_2$
(d) $AlPO_4$
(e) $AgCH_3CO_2$

2.53 Compounds with Na^+: Na_2CO_3 (sodium carbonate) and NaI (sodium iodide). Compounds with Ba^{2+}: $BaCO_3$ (barium carbonate) and BaI_2 (barium iodide).

2.55 The force of attraction is stronger in NaF than in NaI because the distance between ion centers is smaller in NaF (235 pm) than in NaI (322 pm).

2.57 (a) Nitrogen trifluoride
(b) Hydrogen iodide
(c) Boron triiodide
(d) Phosphorus pentafluoride

2.59 (a) SCl_2
(b) N_2O_5
(c) $SiCl_4$
(d) B_2O_3

2.61 (a) 67 g Al

2.111 $(NH_4)_2CO_3$, $(NH_4)_2SO_4$, $NiCO_3$, $NiSO_4$

2.113 All of these compounds have one atom of some element plus three Cl atoms. The highest mass percent of chlorine will occur in the compound having the lightest central element. Here, that element is B, so BCl_3 should have the highest mass percent of Cl (90.77%).

2.115 The molar mass of adenine ($C_5H_5N_5$) is 135.13 g/mol. 3.0×10^{23} molecules represents 67 g. Thus, 3.0×10^{23} molecules of adenine has a larger mass than 40.0 g of the compound.

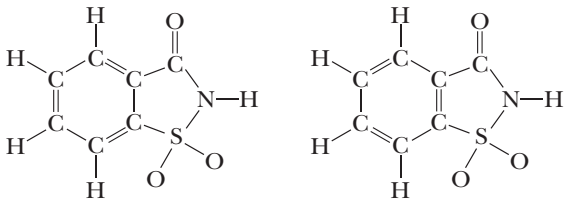
2.117 1.7×10^{21} molecules of water

2.119 245.75 g/mol. Mass percent: 25.86% Cu, 22.80% N, 5.742% H, 13.05% S, and 32.55% O. In 10.5 g of compound there are 2.72 g Cu and 0.770 g H_2O.

2.121 Empirical formula of malic acid: $C_4H_6O_5$

2.123 $Fe_2(CO)_9$

2.125 (a) $C_7H_5NO_3S$



(b) 6.82×10^{-4} mol saccharin
(c) 21.9 mg S

2.127 (a) NaClO, ionic
(b) BI_3
(c) $Al(ClO_4)_3$, ionic
(d) $Ca(CH_3CO_2)_2$, ionic
(e) $KMnO_4$, ionic
(f) $(NH_4)_2SO_3$, ionic
(g) KH_2PO_4, ionic
(h) S_2Cl_2
(i) ClF_3
(j) PF_3

2.129 (a) Empirical formula = molecular formula = CF_2O_2
(b) Empirical formula = C_5H_4; molecular formula = $C_{10}H_8$

2.131 Empirical formula and molecular formula = $C_5H_{14}N_2$

2.133 $C_9H_7MnO_3$

2.135 68.42% Cr; 1.2×10^3 kg Cr_2O_3

2.137 Empirical formula = ICl_3; molecular formula = I_2Cl_6

2.139 7.35 kg of iron

2.141 (d) Na_2MoO_4

2.143 5.52×10^{-4} mol $C_{21}H_{15}Bi_3O_{12}$; 0.346 g Bi

2.145 The molar mass of the compound is 154 g/mol. The unknown element is carbon.

2.147 $n = 2.19 \times 10^3$

2.149 (a) 2.3×10^{14} g/cm^3
(b) 3.34×10^{-3} g/cm^3
(c) The nucleus is much more dense than the space occupied by the electrons.

2.151 (a) 0.0130 mol Ni
(b) NiF_2
(c) Nickel(II) fluoride

2.153 Volume = 3.0 cm^3; length of side = 1.4 cm

2.155 (a) $m/Z = 50$ is $^{12}C^1H_3{}^{35}Cl^+$; $m/Z = 52$ is $^{12}C^1H_3{}^{37}Cl^+$
The height of the line at $m/Z = 52$ is about 1/3 the height of the line at $m/Z = 50$ because the abundance of ^{37}Cl is about 1/3 that of ^{35}Cl.
(b) $^{13}C^1H_3{}^{35}Cl^+$ (a small portion of this peak is also due to $^{12}C^2H^1H_2{}^{35}Cl^+$)

2.157 Formula is $MgSO_4 \cdot 7\ H_2O$

2.159 SnI_4

2.161 (c) The calculated mole ratio is 0.78 mol H_2O per mol $CaCl_2$. The student should heat the crucible again and then reweigh it. More water might be driven off.

2.163 Required data: density of iron (d), molar mass of iron (b), Avogadro's number (c)

$$1.00\ \text{cm}^3\left(\frac{7.87\ \text{g}}{1\ \text{cm}^3}\right)\left(\frac{1\ \text{mol}}{55.85\ \text{g}}\right)\left(\frac{6.022 \times 10^{23}\ \text{atoms}}{1\ \text{mol}}\right) = 8.49 \times 10^{22}\ \text{atoms Fe}$$

2.165 (a) Barium would be more reactive than calcium, so a more vigorous evolution of hydrogen should occur.
(b) Reactivity generally increases on descending the periodic table, at least for Groups 1A and 2A.

Chapter 3

Case Study

Killing Bacteria with Silver

1. 100×10^{15} Ag^+ ions (1 mol/6.022×10^{23} ions) = 2×10^{-7} mol Ag^+

2. 2×10^{-7} mol Ag^+ (107.9 g Ag^+/1 mol Ag^+) = 2×10^{-5} g Ag^+ ions

Check Your Understanding

3.1 (a) $2\ C_4H_{10}(g) + 13\ O_2(g) \rightarrow 8\ CO_2(g) + 10\ H_2O(g)$
(b) $2\ C_3H_7BO_3(\ell) + 8\ O_2(g) \rightarrow 6\ CO_2(g) + 7\ H_2O(g) + B_2O_3(s)$

3.2 (a) $LiNO_3$ is soluble and gives $Li^+(aq)$ and $NO_3^-(aq)$ ions.
(b) $CaCl_2$ is soluble and gives $Ca^{2+}(aq)$ and $Cl^-(aq)$ ions.
(c) CuO is not water soluble.
(d) $NaCH_3CO_2$ is soluble and gives $Na^+(aq)$ and $CH_3CO_2^-(aq)$ ions.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3.3 (a) $Na_2CO_3(aq) + CuCl_2(aq) \rightarrow 2\ NaCl(aq) + CuCO_3(s)$
(b) No reaction; no insoluble compound is produced.
(c) $NiCl_2(aq) + 2\ KOH(aq) \rightarrow Ni(OH)_2(s) + 2\ KCl(aq)$

3.4 (a) $3\ CaCl_2(aq) + 2\ Na_3PO_4(aq) \rightarrow Ca_3(PO_4)_2(s) + 6\ NaCl(aq)$
$3\ Ca^{2+}(aq) + 2\ PO_4^{3-}(aq) \rightarrow Ca_3(PO_4)_2(s)$
(b) $FeCl_3(aq) + 3\ KOH(aq) \rightarrow Fe(OH)_3(s) + 3\ KCl(aq)$
$Fe^{3+}(aq) + 3\ OH^-(aq) \rightarrow Fe(OH)_3(s)$
(c) $Pb(NO_3)_2(aq) + 2\ KCl(aq) \rightarrow PbCl_2(s) + 2\ KNO_3(aq)$
$Pb^{2+}(aq) + 2\ Cl^-(aq) \rightarrow PbCl_2(s)$

3.5 (a) $H_3PO_4(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + H_2PO_4^-(aq)$
(b) Acting as an acid:
$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons HPO_4^{2-}(aq) + H_3O^+(\ell)$
Acting as a base:
$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3PO_4(aq) + OH^-(aq)$
Because $H_2PO_4^-(aq)$ can react as a Brønsted acid and as a base, it is said to be amphiprotic.

3.6 $Mg(OH)_2(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + 2\ H_2O(\ell)$
Net ionic equation:
$Mg(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Mg^{2+}(aq) + 4\ H_2O(\ell)$

3.7 $BaCO_3(s) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$
Barium carbonate and nitric acid produce barium nitrate, carbon dioxide, and water.

3.8 (a) Fe in Fe_2O_3, +3; (b) S in H_2SO_4, +6;
(c) C in CO_3^{2-}, +4; (d) N in NO_2^+, +5

3.9 Dichromate ion is the oxidizing agent and is reduced. (Cr with a +6 oxidation number is reduced to Cr^{3+} with a +3 oxidation number.) Ethanol is the reducing agent and is oxidized. (The C atoms in ethanol have an oxidation number of −2. The oxidation number is 0 in acetic acid.)

3.10 (a) Gas-forming reaction:
$CuCO_3(s) + H_2SO_4(aq) \rightarrow CuSO_4(aq) + H_2O(\ell) + CO_2(g)$
Net ionic equation:
$CuCO_3(s) + 2\ H_3O^+(aq) \rightarrow Cu^{2+}(aq) + 3\ H_2O(\ell) + CO_2(g)$
(b) Oxidation–reduction:
$4\ Ga(s) + 3\ O_2(g) \rightarrow 2\ Ga_2O_3(s)$
(c) Acid–base reaction:
$Ba(OH)_2(aq) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + 2\ H_2O(\ell)$
Net ionic equation:
$OH^-(aq) + H_3O^+(aq) \rightarrow 2\ H_2O(\ell)$
(d) Precipitation reaction:
$CuCl_2(aq) + (NH_4)_2S(aq) \rightarrow CuS(s) + 2\ NH_4Cl(aq)$
Net ionic equation:
$Cu^{2+}(aq) + S^{2-}(aq) \rightarrow CuS(s)$

Review & Check

Section 3-1

1. (b) 2, 3, 1

2. (c) 12,000

Section 3-2

1. (b) 9 O_2, 8 H_2O

Section 3-3

1. (d) All chemical reactions are product-favored at equilibrium.

Section 3-4

1. (a) $Ba(NO_3)_2$

2. (b) Ca^{2+} and 2 NO_3^-

3. (b) acetic acid

Section 3-5

1. (c) acid–base and precipitation

Applying Chemical Principles: Superconductors

1. In this case, because you know that Cu has an implied subscript of 1, divide the number of moles of each element determined by the number of moles of Cu.
$x = 0.15$; Formula = $La_{1.85}Ba_{0.15}CuO_4$

3. One formula unit of the compound contains two Cu^{2+} ions and one Cu^{3+} ion.

5. 0.011 g O_2

Study Questions

3.1 (a) $2\ Al(s) + Fe_2O_3(s) \rightarrow 2\ Fe(\ell) + Al_2O_3(s)$
So much energy is released as heat in this reaction that the iron formed is in the liquid state.

(b) $C(s) + H_2O(g) \rightarrow CO(g) + H_2(g)$
(c) $SiCl_4(\ell) + 2\ Mg(s) \rightarrow Si(s) + 2\ MgCl_2(s)$

3.3 (a) $4\ Cr(s) + 3\ O_2(g) \rightarrow 2\ Cr_2O_3(s)$
(b) $Cu_2S(s) + O_2(g) \rightarrow 2\ Cu(s) + SO_2(g)$
(c) $C_6H_5CH_3(\ell) + 9\ O_2(g) \rightarrow 4\ H_2O(\ell) + 7\ CO_2(g)$

3.5 (a) $Fe_2O_3(s) + 3\ Mg(s) \rightarrow 3\ MgO(s) + 2\ Fe(s)$
Reactants = iron(III) oxide, magnesium
Products = magnesium oxide, iron
(b) $AlCl_3(s) + 3\ NaOH(aq) \rightarrow Al(OH)_3(s) + 3\ NaCl(aq)$
Reactants = aluminum chloride, sodium hydroxide
Products = aluminum hydroxide, sodium chloride
(c) $2\ NaNO_3(s) + H_2SO_4(aq) \rightarrow Na_2SO_4(s) + 2\ HNO_3(aq)$
Reactants = sodium nitrate, sulfuric acid
Products = sodium sulfate, nitric acid
(d) $NiCO_3(s) + 2\ HNO_3(aq) \rightarrow Ni(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$
Reactants = nickel(II) carbonate, nitric acid
Products = nickel(II) nitrate, carbon dioxide, water

3.7 The reaction involving HCl is more product-favored at equilibrium.

3.9 Electrolytes are compounds whose aqueous solutions conduct electricity. Given an aqueous solution containing a strong electrolyte and another aqueous solution containing a weak electrolyte at the same concentration, the solution containing the strong electrolyte (such as NaCl) will conduct electricity much better than the one containing the weak electrolyte (such as acetic acid).

3.11 (a) $CuCl_2$
(b) $AgNO_3$
(c) All are water-soluble.

3.13 (a) K^+ and OH^- ions
(b) K^+ and SO_4^{2-} ions
(c) Li^+ and NO_3^- ions
(d) NH_4^+ and SO_4^{2-} ions

3.15 (a) Soluble, Na^+ and CO_3^{2-} ions
(b) Soluble, Cu^{2+} and SO_4^{2-} ions
(c) Insoluble
(d) Soluble, Ba^{2+} and Br^- ions

3.17 $CdCl_2(aq) + 2\ NaOH(aq) \rightarrow Cd(OH)_2(s) + 2\ NaCl(aq)$
$Cd^{2+}(aq) + 2\ OH^-(aq) \rightarrow Cd(OH)_2(s)$

3.19 (a) $NiCl_2(aq) + (NH_4)_2S(aq) \rightarrow NiS(s) + 2\ NH_4Cl(aq)$
$Ni^{2+}(aq) + S^{2-}(aq) \rightarrow NiS(s)$
(b) $3\ Mn(NO_3)_2(aq) + 2\ Na_3PO_4(aq) \rightarrow Mn_3(PO_4)_2(s) + 6\ NaNO_3(aq)$
$3\ Mn^{2+}(aq) + 2\ PO_4^{3-}(aq) \rightarrow Mn_3(PO_4)_2(s)$

3.21 $HNO_3(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + NO_3^-(aq)$

3.23 $H_2C_2O_4(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + HC_2O_4^-(aq)$
$HC_2O_4^-(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + C_2O_4^{2-}(aq)$

3.25 $MgO(s) + H_2O(\ell) \rightarrow Mg(OH)_2(s)$

3.27 (a) Acetic acid reacts with magnesium hydroxide to give magnesium acetate and water.
$2\ CH_3CO_2H(aq) + Mg(OH)_2(s) \rightarrow Mg(CH_3CO_2)_2(aq) + 2\ H_2O(\ell)$
(b) Perchloric acid reacts with ammonia to give ammonium perchlorate
$HClO_4(aq) + NH_3(aq) \rightarrow NH_4ClO_4(aq)$

3.29 $Ba(OH)_2(aq) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + 2\ H_2O(\ell)$

3.31 $HNO_3(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + NO_3^-(aq)$
Brønsted acids: $HNO_3(aq)$ and $H_3O^+(aq)$
Brønsted bases: $H_2O(\ell)$ and $NO_3^-(aq)$
HNO_3 is a strong acid; therefore, this reaction is product-favored at equilibrium.

3.33 $H_2O(\ell) + HBr(aq) \rightleftharpoons H_3O^+(aq) + Br^-(aq)$
Water accepts H^+ from HBr(aq)
$H_2O(\ell) + NH_3(aq) \rightleftharpoons OH^-(aq) + NH_4^+(aq)$
Water donates H^+ to $NH_3(aq)$

3.35 (a) $(NH_4)_2CO_3(aq) + Cu(NO_3)_2(aq) \rightarrow CuCO_3(s) + 2\ NH_4NO_3(aq)$
$CO_3^{2-}(aq) + Cu^{2+}(aq) \rightarrow CuCO_3(s)$
(b) $Pb(OH)_2(s) + 2\ HCl(aq) \rightarrow PbCl_2(s) + 2\ H_2O(\ell)$
$Pb(OH)_2(s) + 2\ H_3O^+(aq) + 2\ Cl^-(aq) \rightarrow PbCl_2(s) + 4\ H_2O(\ell)$
(c) $BaCO_3(s) + 2\ HCl(aq) \rightarrow BaCl_2(aq) + H_2O(\ell) + CO_2(g)$
$BaCO_3(s) + 2\ H_3O^+(aq) \rightarrow Ba^{2+}(aq) + 3\ H_2O(\ell) + CO_2(g)$
(d) $2\ CH_3CO_2H(aq) + Ni(OH)_2(s) \rightarrow Ni(CH_3CO_2)_2(aq) + 2\ H_2O(\ell)$
$2\ CH_3CO_2H(aq) + Ni(OH)_2(s) \rightarrow Ni^{2+}(aq) + 2\ CH_3CO_2^-(aq) + 2\ H_2O(\ell)$

3.37 (a) $AgNO_3(aq) + KI(aq) \rightarrow AgI(s) + KNO_3(aq)$
$Ag^+(aq) + I^-(aq) \rightarrow AgI(s)$
(b) $Ba(OH)_2(aq) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + 2\ H_2O(\ell)$
$OH^-(aq) + H_3O^+(aq) \rightarrow 2\ H_2O(\ell)$
(c) $2\ Na_3PO_4(aq) + 3\ Ni(NO_3)_2(aq) \rightarrow Ni_3(PO_4)_2(s) + 6\ NaNO_3(aq)$
$2\ PO_4^{3-}(aq) + 3\ Ni^{2+}(aq) \rightarrow Ni_3(PO_4)_2(s)$

3.39 (a) $HNO_2(aq) + OH^-(aq) \rightarrow NO_2^-(aq) + H_2O(\ell)$
(b) $Ca(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Ca^{2+}(aq) + 4\ H_2O(\ell)$

3.41 $FeCO_3(s) + 2\ HNO_3(aq) \rightarrow Fe(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$
Iron(II) carbonate reacts with nitric acid to give iron(II) nitrate, carbon dioxide, and water.

3.43 $(NH_4)_2S(aq) + 2\ HBr(aq) \rightarrow 2\ NH_4Br(aq) + H_2S(g)$
Ammonium sulfide reacts with hydrobromic acid to give ammonium bromide and hydrogen sulfide.

3.45 (a) Br = +5 and O = −2
(b) C = +3 each and O = −2
(c) F = −1
(d) Ca = +2 and H = −1
(e) H = +1, Si = +4, and O = −2
(f) H = +1, S = +6, and O = −2

3.47 (a) Oxidation–reduction
Zn is oxidized from 0 to +2, and N in NO_3^- is reduced from +5 to +4 in NO_2.
(b) Acid–base reaction
(c) Oxidation–reduction
Calcium is oxidized from 0 to +2 in $Ca(OH)_2$, and H is reduced from +1 in H_2O to 0 in H_2.

3.49 (a) O_2 is the oxidizing agent (as it always is), so C_2H_4 is the reducing agent. In this process, C_2H_4 is oxidized, and O_2 is reduced.
(b) Si is oxidized from 0 in Si to +4 in $SiCl_4$. Cl_2 is reduced from 0 in Cl_2 to −1 in Cl^-. Si is the reducing agent, and Cl_2 is the oxidizing agent.

3.51 (a) Acid–base

$$Ba(OH)_2(aq) + 2\ HCl(aq) \rightarrow BaCl_2(aq) + 2\ H_2O(\ell)$$

(b) Gas-forming

$$2\ HNO_3(aq) + CoCO_3(s) \rightarrow Co(NO_3)_2(aq) + H_2O(\ell) + CO_2(g)$$

(c) Precipitation

$$2\ Na_3PO_4(aq) + 3\ Cu(NO_3)_2(aq) \rightarrow Cu_3(PO_4)_2(s) + 6\ NaNO_3(aq)$$

3.53 (a) Precipitation

$$MnCl_2(aq) + Na_2S(aq) \rightarrow MnS(s) + 2\ NaCl(aq)$$

$$Mn^{2+}(aq) + S^{2-}(aq) \rightarrow MnS(s)$$

(b) Precipitation

$$K_2CO_3(aq) + ZnCl_2(aq) \rightarrow ZnCO_3(s) + 2\ KCl(aq)$$

$$CO_3^{2-}(aq) + Zn^{2+}(aq) \rightarrow ZnCO_3(s)$$

3.55 (a) $CuCl_2(aq) + H_2S(aq) \rightarrow CuS(s) + 2\ HCl(aq)$; precipitation
(b) $H_3PO_4(aq) + 3\ KOH(aq) \rightarrow 3\ H_2O(\ell) + K_3PO_4(aq)$
acid–base
(c) $Ca(s) + 2\ HBr(aq) \rightarrow H_2(g) + CaBr_2(aq)$
oxidation–reduction and gas-forming
(d) $MgCl_2(aq) + 2\ NaOH(aq) \rightarrow Mg(OH)_2(s) + 2\ NaCl(aq)$
precipitation

3.57 (a) $Ca(OH)_2(s) + 2\ HBr(aq) \rightarrow 2\ H_2O(\ell) + CaBr_2(aq)$
(b) $MgCO_3(s) + 2\ HNO_3(aq) \rightarrow Mg(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$
(c) $BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$
(d) $NH_3(g) + H_2O(\ell) \rightarrow NH_4^+(aq) + OH^-(aq)$

3.59 (a) $CO_2(g) + 2\ NH_3(g) \rightarrow NH_2CONH_2(s) + H_2O(\ell)$
(b) $UO_2(s) + 4\ HF(aq) \rightarrow UF_4(s) + 2\ H_2O(\ell)$

$$UF_4(s) + F_2(g) \rightarrow UF_6(s)$$

(c) $TiO_2(s) + 2\ Cl_2(g) + 2\ C(s) \rightarrow TiCl_4(\ell) + 2\ CO(g)$

$$TiCl_4(\ell) + 2\ Mg(s) \rightarrow Ti(s) + 2\ MgCl_2(s)$$

3.61 (a) NaBr, KBr, or other alkali metal bromides; Group 2A bromides; other metal bromides except AgBr, Hg_2Br_2, and $PbBr_2$
(b) $Al(OH)_3$ and transition metal hydroxides
(c) Alkaline earth carbonates ($CaCO_3$) or transition metal carbonates ($NiCO_3$)
(d) Metal nitrates are generally water-soluble [e.g., $NaNO_3$, $Ni(NO_3)_2$].
(e) CH_3CO_2H, other acids containing the $—CO_2H$ group

3.63 Water soluble: $Cu(NO_3)_2$, $CuCl_2$. Water insoluble: $CuCO_3$, $Cu_3(PO_4)_2$

3.65 $2\ H_3O^+(aq) + Mg(OH)_2(s) \rightarrow 4\ H_2O(\ell) + Mg^{2+}(aq)$
Spectator ion, NO_3^-. Acid–base reaction.

3.67 (a) Cl_2 is reduced (to Cl^-) and Br^- is oxidized (to Br_2).
(b) Cl_2 is the oxidizing agent and Br^- is the reducing agent.

3.69 (a) $MgCO_3(s) + 2\ H_3O^+(aq) \rightarrow CO_2(g) + Mg^{2+}(aq) + 3\ H_2O(\ell)$
Chloride ion (Cl^-) is the spectator ion.
(b) Gas-forming reaction

3.71 (a) H_2O, NH_3, NH_4^+, and OH^- (and a trace of H_3O^+)
weak Brønsted base
(b) H_2O, CH_3CO_2H, $CH_3CO_2^-$, and H_3O^+ (and a trace of OH^-)
weak Brønsted acid
(c) H_2O, Na^+, and OH^- (and a trace of H_3O^+)
strong Brønsted base
(d) H_2O, H_3O^+, and Br^- (and a trace of OH^-)
strong Brønsted acid

3.73 (a) $K_2CO_3(aq) + 2\ HClO_4(aq) \rightarrow 2\ KClO_4(aq) + CO_2(g) + H_2O(\ell)$
gas-forming
Potassium carbonate and perchloric acid react to form potassium perchlorate, carbon dioxide, and water.

$$CO_3^{2-}(aq) + 2\ H_3O^+(aq) \rightarrow CO_2(g) + 3\ H_2O(\ell)$$

(b) $FeCl_2(aq) + (NH_4)_2S(aq) \rightarrow FeS(s) + 2\ NH_4Cl(aq)$
precipitation
Iron(II) chloride and ammonium sulfide react to form iron(II) sulfide and ammonium chloride.

$$Fe^{2+}(aq) + S^{2-}(aq) \rightarrow FeS(s)$$

(c) $Fe(NO_3)_2(aq) + Na_2CO_3(aq) \rightarrow FeCO_3(s) + 2\ NaNO_3(aq)$
precipitation
Iron(II) nitrate and sodium carbonate react to form iron(II) carbonate and sodium nitrate

$$Fe^{2+}(aq) + CO_3^{2-}(aq) \rightarrow FeCO_3(s)$$

(d) $3\ NaOH(aq) + FeCl_3(aq) \rightarrow 3\ NaCl(aq) + Fe(OH)_3(s)$
precipitation
Sodium hydroxide and iron(III) chloride react to form sodium chloride and iron(III) hydroxide.

$$3\ OH^-(aq) + Fe^{3+}(aq) \rightarrow Fe(OH)_3(s)$$

3.75 (a) NaOH
(b) $MgCl_2$
(c) KI
(d) NH_4Cl

3.77 (a) NH_3
(b) CH_3CO_2H, HF

3.79 $2\ H_3O^+(aq) + S^{2-}(aq) \rightarrow H_2S(g) + 2\ H_2O(\ell)$
$H_2S(g) + Pb^{2+}(aq) + 2\ H_2O(\ell) \rightarrow PbS(s) + 2\ H_3O^+(aq)$

3.81 (a) Reactants: Na(+1), I(−1), H(+1), S(+6), O(−2), Mn(+4)
Products: Na(+1), S(+6), O(−2), Mn(+2), I(0), H(+1)
(b) The oxidizing agent is MnO_2, and NaI is oxidized. The reducing agent is NaI, and MnO_2 is reduced.
(c) Based on the picture, the reaction is product-favored.
(d) Sodium iodide, sulfuric acid, and manganese(IV) oxide react to form sodium sulfate, manganese(II) sulfate, iodine, and water.

3.83 Among the reactions that could be used are the following:
$MgCO_3(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + CO_2(g) + H_2O(\ell)$
$MgS(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + H_2S(g)$
$MgSO_3(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + SO_2(g) + H_2O(\ell)$
In each case, the resulting solution could be evaporated to obtain the desired magnesium chloride.

3.85 The Ag^+ was reduced (to silver metal), and the glucose was oxidized (to $C_6H_{12}O_7$). The Ag^+ is the oxidizing agent, and the glucose is the reducing agent.

3.87 Weak electrolyte test: Compare the conductivity of a solution of lactic acid and that of an equal concentration of a strong acid. The conductivity of the lactic acid solution should be significantly less.
Reversible reaction: The fact that lactic acid is an electrolyte indicates that the reaction proceeds in the forward direction. To test whether the ionization is reversible, one could prepare a solution containing as much lactic acid as it will hold and then add a strong acid (to provide H_3O^+). If the reaction proceeds in the reverse direction, this will cause some lactic acid to precipitate.

3.89 (a) Several precipitation reactions are possible:
i. $BaCl_2(aq) + H_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ HCl(aq)$
ii. $BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$
iii. $Ba(OH)_2(aq) + H_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ H_2O(\ell)$
(b) Gas-forming reaction:
$BaCO_3(s) + H_2SO_4(aq) \rightarrow BaSO_4(s) + CO_2(g) + H_2O(\ell)$

3.91 $NiC_8H_{14}N_4O_4$

3.93 (a) Reactants: As: +3; S: −2; N: +5
Products: As: +5; S: 0; N: +2
(b) Ag_3AsO_4

Chapter 4

Case Studies

Green Chemistry and Atom Economy

Reactant molecules contain 5 C, 10 H, 3 O. Combined molar mass = 118.1 g/mol

Desired product (methyl methacrylate) contains 5 C, 8 H, 2 O. Molar mass = 100.1 g/mol

% Atom economy = (100.1/118.1) × 100 = 84.75%

How Much Salt Is There in Seawater?

1. Step 1: Calculate the amount of Cl^- in the diluted solution from titration data.

Mol Cl^- in 50 mL of dilute solution = mol Ag^+ = (0.100 mol/L)(0.02625 L) = 2.63×10^{-3} mol Cl^-

Step 2: Calculate the concentration of Cl^- in the dilute solution.

Concentration of Cl^- in dilute solution = 2.63×10^{-3} mol/0.0500 L = 5.25×10^{-2} M

Step 3: Calculate the concentration of Cl^- in seawater.

Seawater was initially diluted to one hundredth its original concentration. Thus, the concentration of Cl^- in seawater (undiluted) = 5.25 M

Forensic Chemistry: Titrations and Food Tampering

1. Step 1: Calculate the amount of I_2 in solution from titration data.

Amount I_2 = (0.0425 mol $S_2O_3^{2-}$/L)(0.0253 L)(1 mol I_2/2 mol $S_2O_3^{2-}$) = 5.38×10^{-4} mol I_2

Step 2: Calculate the amount of NaClO present based on the amount of I_2 formed, and from that value calculate the mass of NaClO.

Mass NaClO = 5.38×10^{-4} mol I_2 (1 mol HClO/1 mol I_2)(1 mol NaClO/1 mol HClO)(74.44 g NaClO/1 mol NaClO) = 0.0400 g NaClO

Check Your Understanding

4.1 (454 g C_3H_8)(1 mol C_3H_8/44.10 g C_3H_8) = 10.3 mol C_3H_8

10.3 mol C_3H_8 (5 mol O_2/1 mol C_3H_8)(32.00 g O_2/1 mol O_2) = 1650 g O_2

(10.3 mol C_3H_8)(3 mol CO_2/1 mol C_3H_8)(44.01 g CO_2/1 mol CO_2) = 1360 g CO_2

(10.3 mol C_3H_8)(4 mol H_2O/1 mol C_3H_8)(18.02 g H_2O/1 mol H_2O) = 742 g H_2O

4.2 (a) Amount Al = (50.0 g Al)(1 mol Al/26.98 g Al) = 1.85 mol Al

Amount Fe_2O_3 = (50.0 g Fe_2O_3)(1 mol Fe_2O_3/159.7 g Fe_2O_3) = 0.313 mol Fe_2O_3

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Mol Al/mol Fe_2O_3 = 1.85/0.313 = 5.92

This is more than the 2:1 ratio required, so the limiting reactant is Fe_2O_3.

(b) Mass Fe = (0.313 mol Fe_2O_3)(2 mol Fe/1 mol Fe_2O_3) (55.85 g Fe/1 mol Fe) = 35.0 g Fe

4.3 (0.143 g O_2)(1 mol O_2/32.00 g O_2)(3 mol TiO_2/3 mol O_2)(79.87 g TiO_2/1 mol TiO_2) = 0.357 g TiO_2

Percent TiO_2 in sample = (0.357 g/2.367 g)(100%) = 15.1%

4.4 (1.612 g CO_2)(1 mol CO_2/44.010 g CO_2)(1 mol C/1 mol CO_2) = 0.03663 mol C

(0.7425 g H_2O)(1 mol H_2O/18.015 g H_2O)(2 mol H/1 mol H_2O) = 0.08243 mol H

0.08243 mol H/0.03663 mol = 2.250 H/1 C = 9 H/4 C

The empirical formula is C_4H_9, which has a molar mass of 57 g/mol. This is one half of the measured value of molar mass, so the molecular formula is C_8H_{18}.

4.5 (0.240 g CO_2)(1 mol CO_2/44.01 g CO_2) (1 mol C/1 mol CO_2)(12.01 g C/1 mol C) = 0.06549 g C

(0.0982 g H_2O)(1 mol H_2O/18.02 g H_2O)(2 mol H/1 mol H_2O)(1.008 g H/1 mol H) = 0.01099 g H

Mass O (by difference) = 0.1342 g − 0.06549 g − 0.01099 g = 0.0577 g

Amount C = 0.06549 g(1 mol C/12.01 g C) = 0.00545 mol C

Amount H = 0.01099 g H(1 mol H/1.008 g H) = 0.01090 mol H

Amount O = 0.0577 g O(1 mol O/16.00 g O) = 0.00361 mol O

To find a whole-number ratio, divide each value by 0.00361; this gives 1.51 mol C:3.02 mol H:1 mol O. Multiply each value by 2, and round off to 3 mol C:6 mol H:2 mol O. The empirical formula is $C_3H_6O_2$; given the molar mass of 74.1, this is also the molecular formula.

4.6 (26.3 g)(1 mol $NaHCO_3$/84.01 g $NaHCO_3$) = 0.313 mol $NaHCO_3$

0.313 mol $NaHCO_3$/0.200 L = 1.57 M

Ion concentrations: $[Na^+] = [HCO_3^-] = 1.57$ M

4.7 (2.00 M)(V_{conc}) = (1.00 M)(0.250 L); V_{conc} = 0.125 L

To prepare the solution, measure accurately 125 mL of 2.00 M NaOH into a 250-mL volumetric flask, and add water to give a total volume of 250 mL.

4.8 (a) pH = $-\log(2.6 \times 10^{-2})$ = 1.59
(b) $-\log [H^+]$ = 3.80; $[H^+] = 1.6 \times 10^{-4}$ M

4.9 HCl is the limiting reagent.

(0.350 mol HCl/1 L)(0.0750 L)(1 mol CO_2/2 mol HCl)(44.01 g CO_2/1 mol CO_2) = 0.578 g CO_2

4.10 (0.953 mol NaOH/1 L)(0.02833 L NaOH) = 0.0270 mol NaOH

(0.0270 mol NaOH)(1 mol CH_3CO_2H/1 mol NaOH) = 0.0270 mol CH_3CO_2H

(0.0270 mol CH_3CO_2H)(60.05 g/mol) = 1.62 g CH_3CO_2H

0.0270 mol CH_3CO_2H/0.0250 L = 1.08 M

4.11 (0.100 mol HCl/1 L)(0.02967 L) = 0.00297 mol HCl

(0.00297 mol HCl)(1 mol NaOH/1 mol HCl) = 0.00297 mol NaOH

0.00297 mol NaOH/0.02500 L = 0.119 M NaOH

4.12 Moles acid = moles base = (0.323 mol/L)(0.03008 L) = 9.716×10^{-3} mol

Molar mass = 0.856 g acid/9.716×10^{-3} mol acid = 88.1 g/mol

4.13 (0.196 mol $Na_2S_2O_3$/1 L)(0.02030 L) = 0.00398 mol $Na_2S_2O_3$

(0.00398 mol $Na_2S_2O_3$)(1 mol I_2/2 mol $Na_2S_2O_3$) = 0.00199 mol I_2

0.00199 mol I_2 is in excess and was not used in the reaction with ascorbic acid.

I_2 originally added = (0.0520 mol I_2/1 L)(0.05000 L) = 0.00260 mol I_2

I_2 used in reaction with ascorbic acid = 0.00260 mol − 0.00199 mol = 6.1×10^{-4} mol I_2

(6.1×10^{-4} mol I_2)(1 mol $C_6H_8O_6$/1 mol I_2)(176.1 g/1 mol) = 0.11 g $C_6H_8O_6$

4.14 A Beer's Law plot of the calibration data was constructed by plotting concentration of Cu^{2+} along the x-axis and the absorbance along the y-axis. The equation for the best-fit line is $y = 13.0x + 0.011$.

Substituting the absorbance for the solution of unknown concentration yields

$$0.418 = 13.0x + 0.011$$

$$x = 0.0315$$

Thus the concentration of Cu^{2+} in the solution of unknown concentration is 0.0315 M

Study Questions

4.1 6.0 mol Al and 335 g Fe

4.3 22.7 g Br_2; 25.3 g Al_2Br_6

4.5 (a) CO_2, carbon dioxide, and H_2O, water
(b) $CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$
(c) 102 g O_2
(d) 128 g products

4.7

Equation	2 PbS(s)	+ 3 O_2(g)	→ 2 PbO(s)	+ 2 SO_2(g)
Initial (mol)	2.50	3.75	0	0
Change (mol)	−2.50	$-\frac{3}{2}(2.50) = -3.75$	$+\frac{2}{2}(2.50) = +2.50$	$+\frac{2}{2}(2.50) = +2.50$
Final (mol)	0	0	2.50	2.50

The amounts table shows that 2.50 mol of PbS requires $\frac{3}{2}(2.50) = 3.75$ mol of O_2 and produces 2.50 mol of PbO and 2.50 mol of SO_2.

4.9 (a) Balanced equation: $4\ Cr(s) + 3\ O_2(g) \rightarrow 2\ Cr_2O_3(s)$
(b) 0.175 g of Cr is equivalent to 0.00337 mol

Equation	4 Cr(s)	+ 3 O_2(g)	→ 2 Cr_2O_3(s)
Initial (mol)	0.00337	0.00252 mol	0
Change (mol)	−0.00337	$-\frac{3}{4}(0.00337) = -0.00252$	$\frac{2}{4}(0.00337) = +0.00168$
Final (mol)	0	0	0.00168

The 0.00168 mol Cr_2O_3 produced corresponds to 0.256 g Cr_2O_3.
(c) 0.081 g O_2

4.11 0.11 mol of Na_2SO_4 and 0.62 mol of C are mixed. Sodium sulfate is the limiting reactant. Therefore, 0.11 mol of Na_2S is formed, or 8.2 g.

4.13 (a) F_2 is the limiting reactant.
(b) 12 mol SF_6

4.15 (a) CH_4 is the limiting reactant.
(b) 375 g H_2
(c) Excess H_2O = 1390 g

4.17 (a) Fe_2O_3 is the limiting reactant.
(b) 6.99 g Fe produced
(c) 16.6 g of aluminum remains
(d) Amounts table

Equation	Fe_2O_3(s)	+ 2 Al(s)	→ 2 Fe(ℓ)	+ Al_2O_3(g)
Initial (mol)	0.0626	0.741	0	0
Change (mol)	−0.0626	−0.125	+0.125	+0.0626
Final (mol)	0	0.616	0.125	0.0626

4.19 (332 g CH_3OH/407 g)100% = 81.6%

4.21 (a) 14.3 g $Cu(NH_3)_4SO_4$
(b) 88.3% yield

4.23 110 g CH_4 required

4.25 91.9% $CuSO_4 \cdot 5\ H_2O$

4.27 84.3% $CaCO_3$

4.29 13.8% NiS

4.31 Empirical formula = CH

4.33 Empirical formula = C_5H_4;
molecular formula = $C_{10}H_8$

4.35 (a) CH_3O (b) $C_2H_6O_2$

4.37 $Ni(CO)_4$

4.39 $[Na_2CO_3] = 0.254$ M; $[Na^+] = 0.508$ M;
$[CO_3^{2-}] = 0.254$ M

4.41 0.494 g $KMnO_4$

4.43 5.08×10^3 mL

4.45 (a) 0.50 M NH_4^+ and 0.25 M SO_4^{2-}
(b) 0.246 M Na^+ and 0.123 M CO_3^{2-}
(c) 0.056 M H_3O^+ and 0.056 M NO_3^-

4.47 A mass of 1.06 g of Na_2CO_3 is required. After weighing out this quantity of Na_2CO_3, transfer it to a 500.-mL volumetric flask. Rinse any solid from the neck of the flask while filling the flask with distilled water. Dissolve the solute in water. Add water until the bottom of the meniscus of the water is at the top of the scribed mark on the neck of the flask. Thoroughly mix the solution.

4.49 0.0750 M

4.51 Method (a) is correct. Method (b) gives an acid concentration of 0.15 M.

4.53 0.00340 M

4.55 $[H_3O^+] = 10^{-pH} = 4.0 \times 10^{-4}$ M; the solution is acidic.

4.57 HNO_3 is a strong acid, so $[H_3O^+] = 0.0013$ M. pH = 2.89.

4.137 The balanced chemical equation indicates that the stoichiometric ratio of HCl to Zn is 2 mol HCl/1 mol Zn. In each reaction, there is 0.100 mol of HCl present. In reaction 1, there is 0.107 mol of Zn present. This gives a 0.93 mol HCl/mol Zn ratio, indicating that HCl is the limiting reactant. In reaction 2, there is 0.050 mol of Zn, giving a 2.0 mol HCl/mol Zn ratio. This indicates that the two reactants are present in exactly the correct stoichiometric ratio. In reaction 3, there is 0.020 mol of Zn, giving a 5.0 mol HCl/mol Zn ratio. This indicates that the HCl is present in excess and that the zinc is the limiting reactant.

4.139 If both students base their calculations on the amount of HCl solution pipeted into the flask (20 mL), then the second student's result will be (e), the same as the first student's. However, if the HCl concentration is calculated using the diluted solution volume, student 1 will use a volume of 40 mL, and student 2 will use a volume of 80 mL in the calculation. The second student's result will be (c), half that of the first student's.

4.141 (a) % Atom economy = 44.15%
(b) Theoretical yield of maleic anhydride = 1.26×10^3 g; % yield = 77.4%

The theoretical yield of carbon dioxide from 1.00 kg of benzene is 1.13 kg.

Chapter 5

Case Study

The Fuel Controversy—Alcohol and Gasoline

In the following, we assume water vapor, $H_2O(g)$, is formed upon oxidation.

1. Burning ethanol: $C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$

$\Delta_r H° = (2 \text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)] + (3 \text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)] - (1 \text{ mol } C_2H_5OH/\text{mol-rxn})[\Delta_f H°(C_2H_5OH)]$

$\Delta_r H° = (2 \text{ mol } CO_2/\text{mol-rxn})[-393.5 \text{ kJ/mol } O_2] + (3 \text{ mol } H_2O/\text{mol-rxn})[-241.8 \text{ kJ/mol } H_2O] - (1 \text{ mol } C_2H_5OH/\text{mol-rxn})[-277.0 \text{ kJ/mol } C_2H_5OH)] = -1235.4 \text{ kJ/mol-rxn}$

1 mol ethanol per 1 mol-rxn; therefore, q per mol is −1235.4 kJ/mol

q per gram: $(-1235.4 \text{ kJ/mol})(1 \text{ mol } C_2H_5OH/46.07 \text{ g } C_2H_5OH) = -26.82 \text{ kJ/g } C_2H_5OH$

Burning octane: $C_8H_{18}(\ell) + 12.5\ O_2(g) \rightarrow 8\ CO_2(g) + 9\ H_2O(g)$

$\Delta_r H° = (8 \text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)] + (9 \text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)] - (1 \text{ mol } C_8H_{18}/\text{mol-rxn})[\Delta_f H°(C_8H_{18})]$

$\Delta_r H° = (8 \text{ mol } CO_2/\text{mol-rxn})[-393.5 \text{ kJ/mol } CO_2] + (9 \text{ mol } H_2O/\text{mol-rxn})[-241.8 \text{ kJ/mol } H_2O] - (1 \text{ mol } C_8H_{18}/\text{mol-rxn})[-250.1 \text{ kJ/mol } C_8H_{18})] = -5074.1 \text{ kJ/mol-rxn}$

1 mol octane per mol-rxn; therefore, q per mol octane is −5074.1 kJ/mol

q per gram: $-5074.1 \text{ kJ}/1 \text{ mol } C_8H_{18}$
$(1 \text{ mol } C_8H_{18}/114.2 \text{ g } C_8H_{18}) = -44.43 \text{ kJ/g } C_8H_{18}$

Octane provides more energy per gram than ethanol.

2. For ethanol, per liter: $q = (-26.82 \text{ kJ/g})(785 \text{ g/L}) = -2.11 \times 10^4$ kJ/L

For octane, per liter: $q = (-44.43 \text{ kJ/g})(699 \text{ g/L}) = -3.11 \times 10^4$ kJ/L

Octane produces almost 50% more energy per liter of fuel.

3. Mass of CO_2 per liter of ethanol = 1.000 L $(785 \text{ g } C_2H_5OH/L)(1 \text{ mol } C_2H_5OH/46.07 \text{ g } C_2H_5OH)(2 \text{ mol } CO_2/1 \text{ mol } C_2H_5OH)(44.01 \text{ g } CO_2/1 \text{ mol } CO_2) = 1.50 \times 10^3 \text{ g } CO_2$

Mass of CO_2 per liter of octane = 1.000 L $(699 \text{ g } C_8H_{18}/L)(1 \text{ mol } C_8H_{18}/114.2 \text{ g } C_8H_{18})(8 \text{ mol } CO_2/1 \text{ mol } C_8H_{18})(44.01 \text{ g } CO_2/1 \text{ mol } CO_2) = 2.16 \times 10^3 \text{ g } CO_2$

4. Volume of ethanol needed to obtain 3.11×10^4 kJ of energy from oxidation: $(2.11 \times 10^4 \text{ kJ/L } C_2H_5OH)(x) = 3.11 \times 10^4$ kJ (where x is volume of ethanol)

Volume of ethanol = x = 1.47 L

Mass of CO_2 produced by burning 1.47 L of ethanol = $(1.50 \times 10^3 \text{ g } CO_2/\text{L } C_2H_5OH)(1.47 \text{ L } C_2H_5OH) = 2.22 \times 10^3 \text{ g } CO_2$

To obtain the same amount of energy, slightly more CO_2 is produced by burning ethanol than by burning octane.

5. Your car will travel about 50% farther on a liter of octane, and it will produce slightly less CO_2 emissions, than if you burned 1.0 L of ethanol.

Check Your Understanding

5.1 $C = 59.8 \text{ J}/[(25.0 \text{ g})(1.00 \text{ K})] = 2.39 \text{ J/g} \cdot \text{K}$

5.2 $(15.5 \text{ g})(C_{metal})(18.9 \text{ °C} - 100.0 \text{ °C}) + (55.5 \text{ g})(4.184 \text{ J/g} \cdot \text{K})(18.9 \text{ °C} - 16.5 \text{ °C}) = 0$

$C_{metal} = 0.44 \text{ J/g} \cdot \text{K}$

5.3 1.00 L (1000 mL/1 L)(0.7849 g/cm3) = 785 g

Heat liquid from 25.0 °C to 78.3 °C.

$\Delta T = 78.3 \text{ °C} - 25.0 \text{ °C} = 53.3 \text{ °C} = 53.3 \text{ K}$

$q = (2.44 \text{ J/g} \cdot \text{K})(785 \text{ g})(53.3 \text{ K}) = 1.02 \times 10^5 \text{ J} = 102 \text{ kJ}$

Boil the liquid.

$q = 38.56 \text{ kJ/mol } (785 \text{ g})(1 \text{ mol}/46.08 \text{ g}) = 657 \text{ kJ}$

Total = 102 kJ + 657 kJ = 759 kJ

5.4 Energy transferred as heat from tea + energy as heat expended to melt ice = 0.

$(250 \text{ g})(4.2 \text{ J/g} \cdot \text{K})(273.2 \text{ K} - 291.4 \text{ K}) + x \text{ g } (333 \text{ J/g}) = 0$

$x = 57$ g

57 g of ice melts with energy supplied by cooling 250 g of tea from 18.2 °C (291.4 K) to 0 °C (273.2 K).

Mass of ice remaining = mass of ice initially − mass of ice melted

Mass of ice remaining = 75 g − 57 g = 18 g

5.5 The volume change is (−0.65 L)(1 m^3/1000 L) = -6.5×10^{-4} m^3. Work, $w_p = -P\Delta V$ = $-(1.01 \times 10^5$ kg/m · $s^2)(-6.5 \times 10^{-4}$ $m^3) = 66$ J (work done on the system by the surroundings).

Heat (485 J) is transferred from system; q_p for system = −485 J.

$\Delta U = q_p + w_p = -485$ J + 66 J = −419 J

5.6 (15.0 g C_2H_6)(1 mol C_2H_6/30.07 g C_2H_6) = 0.499 mol C_2H_6

$\Delta H°$ = 0.499 mol C_2H_6(1 mol-rxn/2 mol C_2H_6) (−2857.3 kJ/mol-rxn) = −713 kJ

5.7 Mass of final solution = 400. g

ΔT = 27.78 °C − 25.10 °C = 2.68 °C = 2.68 K

Amount of HCl used = amount of NaOH used = $C \times V$ = (0.400 mol/L) × 0.200 L = 0.0800 mol

Energy transferred as heat by acid−base reaction + energy gained as heat to warm solution = 0

q_{rxn} + (4.20 J/g · K)(400. g)(2.68 K) = 0

$q_{rxn} = -4.50 \times 10^3$ J

This represents the energy transferred as heat in the reaction of 0.0800 mol HCl.

Energy transferred as heat per mole = $\Delta_r H$ = −4.50 kJ/0.0800 mol HCl = −56.3 kJ/mol HCl

5.8 (a) Energy evolved as heat in reaction + energy as heat absorbed by H_2O + energy as heat absorbed by bomb = 0

$q_{rxn} + (1.50 \times 10^3$ g)(4.20 J/g · K)(27.32 °C − 25.00 °C) + (837 J/K)(27.32 °C − 25.00 °C) = 0

q_{rxn} = −16,600 J (energy as heat evolved in burning 1.0 g sucrose)

(b) Energy evolved as heat per mole = (−16.6 kJ/g sucrose)(342.3 g sucrose/1 mol sucrose) = −5670 kJ/mol sucrose

5.9 $C(s) + O_2(g) \rightarrow CO_2(g)$ $\Delta_r H_1° = -393.5$ kJ

$2\,[S(s) + O_2(g) \rightarrow SO_2(g)]$ $\Delta_r H° = 2\,\Delta_r H_2° = 2(-296.8) = -593.6$ kJ

$CO_2(g) + 2\,SO_2(g) \rightarrow CS_2(g) + 3\,O_2(g)$ $\Delta_r H° = -\Delta_r H_3° = +1103.9$ kJ

Net: $C(s) + 2\,S(s) \rightarrow CS_2(g)$

$\Delta_r H°_{net} = -393.5$ kJ + (−593.6 kJ) + 1103.9 kJ = +116.8 kJ

5.10 $\Delta_r H°$ = (6 mol CO_2/mol-rxn)$\Delta_f H°[CO_2(g)]$ + (3 mol H_2O/mol-rxn)$\Delta_f H°[H_2O(\ell)]$ − {(1 mol C_6H_6/1 mol-rxn)$\Delta_f H°[C_6H_6(\ell)]$ + ($^{15}/_2$ mol O_2/mol-rxn) $\Delta_f H°[O_2(g)]$}

= (6 mol/mol-rxn)(−393.5 kJ/mol) + (3 mol/mol-rxn)(−285.8 J/mol) − (1 mol/mol-rxn)(+49.0 kJ/mol) − 0

= −3267.4 kJ/mol-rxn

Review & Check

Section 5-1

1. (a) melting of ice at 0 °C

2. (b) $q < 0$

Section 5-2

1. (a) warming 2.0 g of copper by 10 °C

2. (c) 20 g of water at 20 °C + 10 g of water at 30 °C

Section 5-3

1. (a) Raising the temperature of 100 g of water by 1.0 °C

2. (b) All of the ice melts; liquid water is at a temperature between 0 °C and 10 °C.

Section 5-4

1. (b) 2 and 4

2. (c) $2\,C(s) + O_2(g) \rightarrow 2\,CO(g)$

Section 5-5

1. (c) 90.8 kJ

2. (b) −425 kJ

Section 5-6

1. (b) endothermic

2. (b) The calculated value of $\Delta_{solution}H°$ will be too small.

Section 5-7

1. (d) $Al(s) + 3/2\,Cl_2(g) \rightarrow AlCl_3(s)$

2. (c) $1/2\,\Delta_r H_1° - \Delta_r H_2° + 1/2\,\Delta_r H_3°$

Applying Chemical Principles: Gunpowder

1. (a) $\Delta_r H°$ = −567.9 kJ/mol-rxn
(b) $\Delta H°$ = −2.10 kJ

3. (a) $4\,C_3H_5N_3O_9(\ell) \rightarrow 12\,CO_2(g) + 6\,N_2(g) + 10\,H_2O(g) + O_2(g)$
(b) $\Delta_f H°$ = -3.70×10^2 kJ/mol

Study Questions

5.1 The system is the part of the universe being studied. The surroundings are everything else in the universe that can exchange matter and/or energy with the system. A system and its surroundings are said to be in thermal equilibrium if they can exchange energy with each other but are at the same temperature; therefore, there is no net transfer of energy as heat from one to the other.

5.3 (a) Exothermic
(b) Endothermic
(c) Endothermic
(d) Endothermic

5.5 0.140 J/g · K

5.7 2.44 kJ

5.9 32.8 °C

5.11 20.7 °C

5.13 $T_{initial}$ = 37.4 °C

5.15 0.40 J/g · K

5.17 330 kJ

5.19 49.3 kJ

5.21 273 J

5.23 9.97×10^5 J

5.25 $w = P\Delta V = 126$ J

5.27 $\Delta V = 4.42$ L

5.29 $\Delta U = 433$ J

5.31 $V_{final} = 2.6$ L

5.33 Reaction is exothermic because $\Delta_r H°$ is negative. The heat evolved is 2.38 kJ.

5.35 -3.3×10^4 kJ

5.37 $\Delta H = -56$ kJ/mol CsOH

5.39 0.52 J/g · K

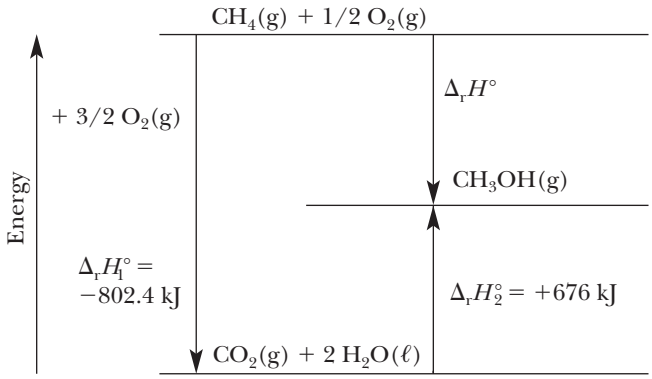
5.41 $\Delta_r H = +23$ kJ/mol-rxn

5.43 −297 kJ/mol SO_2

5.45 -3.09×10^3 kJ/mol $C_6H_5CO_2H$

5.47 0.236 J/g · K

5.49 (a) $\Delta_r H° = -126$ kJ/mol-rxn
(b)



5.51 $\Delta_r H° = +90.3$ kJ/mol-rxn

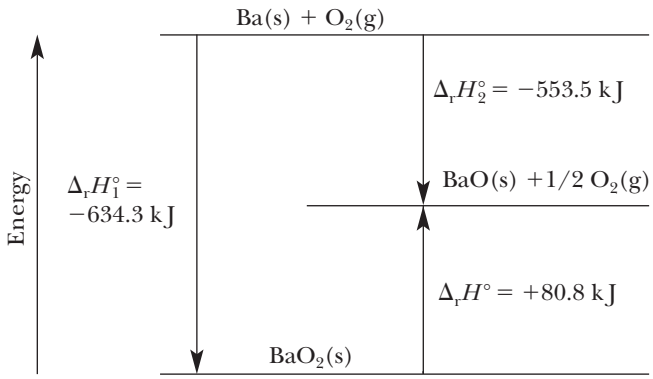
5.53 $C(s) + 2\ H_2(g) + 1/2\ O_2(g) \rightarrow CH_3OH(\ell)$
$\Delta_f H° = -238.4$ kJ/mol

5.55 (a) $2\ Cr(s) + 3/2\ O_2(g) \rightarrow Cr_2O_3(s)$
$\Delta_f H° = -1134.7$ kJ/mol
(b) 2.4 g is equivalent to 0.046 mol of Cr. This will produce 26 kJ of energy transferred as heat.

5.57 (a) $\Delta H° = -24$ kJ for 1.0 g of phosphorus
(b) $\Delta H° = -18$ kJ for 0.20 mol NO
(c) $\Delta H° = -16.9$ kJ for the formation of 2.40 g of NaCl(s)
(d) $\Delta H° = -1.8 \times 10^3$ kJ for the oxidation of 250 g of iron

5.59 (a) $\Delta_r H° = -906.2$ kJ
(b) The heat evolved is 133 kJ for the oxidation of 10.0 g of NH_3

5.61 (a) $\Delta_r H° = +161.6$ kJ/mol-rxn; the reaction is endothermic.
(b)



5.63 $\Delta_f H° = +77.7$ kJ/mol for naphthalene

5.65 (a) Exothermic: a process in which energy is transferred as heat from a system to its surroundings. (The combustion of methane is exothermic.)
Endothermic: a process in which energy is transferred as heat from the surroundings to the system. (Ice melting is endothermic.)
(b) System: the object or collection of objects being studied. (A chemical reaction—the system—taking place inside a calorimeter—the surroundings.)
Surroundings: everything outside the system that can exchange mass or energy with the system. (The calorimeter and everything outside the calorimeter comprise the surroundings.)
(c) Specific heat capacity: the quantity of energy that must be transferred as heat to raise the temperature of 1 gram of a substance 1 kelvin. (The specific heat capacity of water is 4.184 J/g · K.)
(d) State function: a quantity that is characterized by changes that do not depend on the path chosen to go from the initial state to the final state. (Enthalpy and internal energy are state functions.)
(e) Standard state: the most stable form of a substance in the physical state that exists at a pressure of 1 bar and at a specified temperature. (The standard state of carbon at 25 °C is graphite.)
(f) Enthalpy change, ΔH: the energy transferred as heat at constant pressure. (The enthalpy change for melting ice at 0 °C is 6.00 kJ/mol.)
(g) Standard enthalpy of formation: the enthalpy change for the formation of 1 mol of a compound in its standard state directly from the component elements in their standard states. ($\Delta_f H°$ for liquid water is −285.83 kJ/mol.)

5.67 (a) System: reaction between methane and oxygen
Surroundings: the furnace and the rest of the universe. Energy is transferred as heat from the system to the surroundings.

(b) System: water drops

Surroundings: skin and the rest of the universe

Energy is transferred as heat from the surroundings to the system

(c) System: water

Surroundings: freezer and the rest of the universe

Energy is transferred as heat from the system to the surroundings

(d) System: reaction of aluminum and iron(III) oxide

Surroundings: flask, laboratory bench, and rest of the universe

Energy is transferred as heat from the system to the surroundings.

5.69 Standard state of oxygen is gas, $O_2(g)$.

$O_2(g) \rightarrow 2\ O(g)$, $\Delta_r H° = +498.34$ kJ/mol-rxn, endothermic

$3/2\ O_2(g) \rightarrow O_3(g)$, $\Delta_r H° = +142.67$ kJ/mol-rxn

5.71 (a) Energy is transferred as heat from the surroundings to the system and as work done by the system.

(b) Energy is transferred as heat from the surroundings to the system and as work done by the system.

5.73 $\Delta H° = -0.627$ kJ

5.75 $C_{Ag} = 0.24$ J/g · K

5.77 Mass of ice melted = 75.4 g

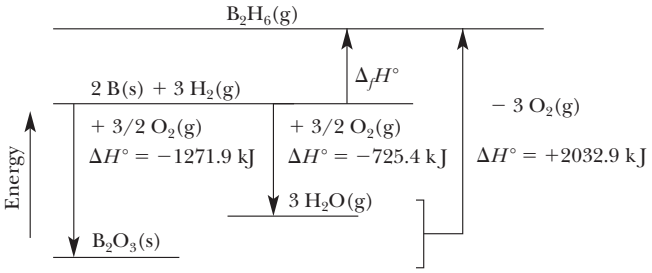
5.79 Final temperature = 278 K (5 °C)

5.81 (a) When summed, the following equations give the balanced equation for the formation of $B_2H_6(g)$ from the elements.

$2\ B(s) + 3/2\ O_2(g) \rightarrow B_2O_3(s)$	$\Delta_r H° = -1271.9$ kJ
$3\ H_2(g) + 3/2\ O_2(g) \rightarrow 3\ H_2O(g)$	$\Delta_r H° = -725.4$ kJ
$B_2O_3(s) + 3\ H_2O(g) \rightarrow B_2H_6(g) + 3\ O_2(g)$	$\Delta_r H° = +2032.9$ kJ
$2\ B(s) + 3\ H_2(g) \rightarrow B_2H_6(g)$	$\Delta_r H° = +35.6$ kJ

(b) The enthalpy of formation of $B_2H_6(g)$ is +35.6 kJ/mol.

(c)



(d) The formation of $B_2H_6(g)$ is endothermic.

5.83 (a) $\Delta_r H° = +131.31$ kJ

(b) Endothermic

(c) 1.0932×10^7 kJ

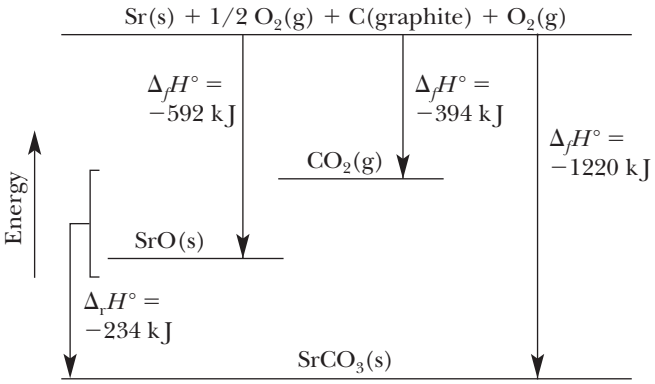
5.85 Assuming $CO_2(g)$ and $H_2O(\ell)$ are the products of combustion:

$\Delta_r H°$ for isooctane is −5461.3 kJ/mol or −47.81 kJ per gram.

$\Delta_r H°$ for liquid methanol is −726.77 kJ/mol or −22.682 kJ per gram.

5.87 (a) Adding the equations as they are given in the question results in the desired equation for the formation of $SrCO_3(s)$. The calculated $\Delta_r H° = -1220.$ kJ/mol.

(b)



5.89 $\Delta_r H° = -305.3$ kJ

5.91 This calculation assumes water vapor, $H_2O(g)$, is formed upon oxidation.

Balanced Equation: $C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$

$\Delta_r H° = (2\ mol\ CO_2/1\ mol\text{-}rxn)[\Delta_f H°\ CO_2(g)] + (3\ mol\ H_2O/1\ mol\text{-}rxn)[\Delta_f H°\ H_2O(g)] - \{(1\ mol\ C_2H_5OH/1\ mol\text{-}rxn)[\Delta_f H°\ C_2H_5OH(\ell)] + (3\ mol\ O_2/1\ mol\text{-}rxn)[\Delta_f H°\ O_2(g)]\}$

$\Delta_r H° = (2\ mol\ CO_2/1\ mol\text{-}rxn)[-393.5\ kJ/mol\ CO_2] + (3\ mol\ H_2O/1\ mol\text{-}rxn)[-241.8\ kJ/mol\ H_2O] - \{(1\ mol\ C_2H_5OH/1\ mol\text{-}rxn)[-277.0\ kJ/mol\ C_2H_5OH] + (3\ mol\ O_2/1\ mol\text{-}rxn)[0\ kJ/mol\ O_2]\}$
$= -1235.4$ kJ/mol-rxn

$100.\ g\ C_2H_5OH\ (1\ mol\ C_2H_5OH/46.07\ g\ C_2H_5OH)(1\ mol\text{-}rxn/1\ mol\ C_2H_5OH)(-1235.4\ kJ/mol\text{-}rxn) = -2680$ kJ

5.93 $C_{Pb} = 0.121$ J/g · K

5.95 $\Delta_r H = -69$ kJ/mol AgCl

5.97 36.0 kJ evolved per mol of NH_4NO_3

5.99 The standard enthalpy change, $\Delta_r H°$, is −352.88 kJ. The quantity of magnesium needed is 0.43 g.

5.101 (a) Exothermic

(b) Exothermic

5.103 The enthalpy change for each of the following three reactions is known or can be measured by calorimetry. The three equations sum to give the enthalpy of formation of $CaSO_4(s)$.

$Ca(s)$	$+ 1/2\ O_2(g)$	$\rightarrow CaO(s)$	$\Delta_r H° = \Delta_f H° = -635.09$ kJ
$1/8\ S_8(s)$	$+ 3/2\ O_2(g)$	$\rightarrow SO_3(g)$	$\Delta_r H° = \Delta_f H° = -395.77$ kJ
$CaO(s)$	$+ SO_3(g)$	$\rightarrow CaSO_4(s)$	$\Delta_r H° = -402.7$ kJ
$Ca(s)$	$+ 1/8\ S_8(s) + 2\ O_2(g)$	$\rightarrow CaSO_4(s)$	$\Delta_r H° = \Delta_f H° = -1433.6$ kJ

5.105

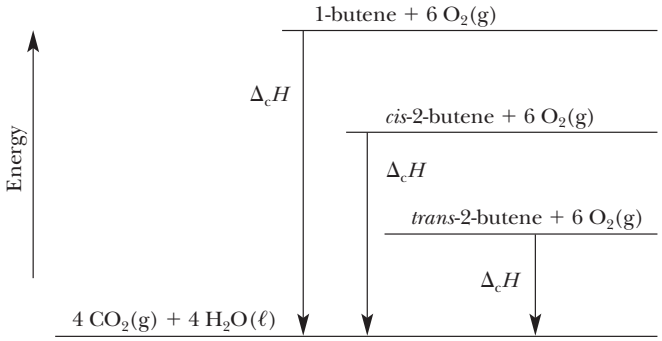
Metal	Molar Heat Capacity (J/mol · K)
Al	24.2
Fe	25.1
Cu	24.5
Au	25.4

All the metals have a molar heat capacity of 24.8 ± 0.5 J/mol · K. Therefore, assuming the molar heat capacity of Ag is 24.8 J/mol · K, its specific heat capacity is 0.230 J/g · K. This is very close to the experimental value of 0.236 J/g · K.

5.107 120 g of CH_4 required (assuming $H_2O(g)$ as product)

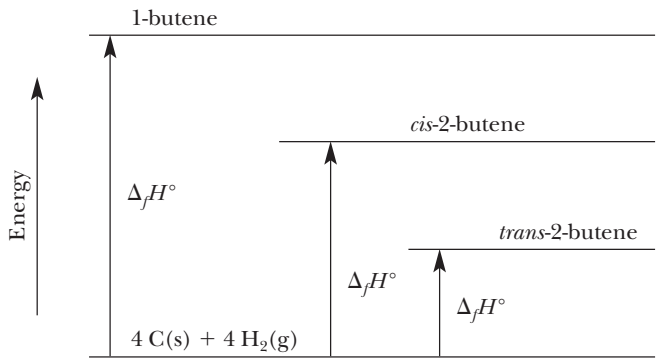
5.109 1.6×10^{11} kJ released to the surroundings. This is equivalent to 3.8×10^4 tons of dynamite.

5.111 (a)



(b) *cis*-2-butene: $\Delta_f H° = -7.6$ kJ/mol
trans-2-butene: $\Delta_f H° = -10.8$ kJ/mol
1-butene: $\Delta_f H° = -0.6$ kJ/mol

(c)



(d) −3.4 kJ/mol-rxn

5.113 (a) −726 kJ/mol Mg
(b) 25.0 °C

5.115 (a) Methane
(b) Methane
(c) −279 kJ
(d) $CH_4(g) + 1/2\ O_2(g) \rightarrow CH_3OH(\ell)$

5.117 (a) Metal heated = 100.0 g of Al; metal cooled = 50.0 g of Au; final temperature = 26 °C
(b) Metal heated = 50.0 g of Zn; metal cooled = 50.0 g of Al; final temperature = 21 °C

5.119 $w = -(1.0\ L \cdot atm)(0.36\ L - 0\ L) = -0.36\ L\ atm = -36\ J$

Thus, 36 J of work is done by the system on the surroundings.

Chapter 6

Case Study

What Makes the Colors in Fireworks?

1. Yellow light is from the 589 and 590 nm emissions.
2. Primary emission for Sr is red. This has a longer wavelength than yellow light.
3. $4\ Mg(s) + KClO_4(s) \rightarrow KCl(s) + 4\ MgO(s)$

Check Your Understanding

6.1 (a) Highest frequency, violet; lowest frequency, red
(b) The wavelength of radiation in a microwave oven is shorter than the FM radio wavelength.
(c) The wavelength of x-rays is shorter than the wavelength of ultraviolet light.
(d) $\lambda = 5.10 \times 10^{-7}$ m
$\nu = c/\lambda = (2.998 \times 10^8\ m/s^{-1})/(5.10 \times 10^{-7}\ m) = 5.88 \times 10^{14}\ s^{-1}$

6.2 $\nu = c/\lambda = (2.998 \times 10^8\ m/s)/(4.05 \times 10^{-7}\ m) = 7.40 \times 10^{14}\ s^{-1}$
$E = N_A h\nu = (6.022 \times 10^{23}\ photons/mole)(6.626 \times 10^{-34}\ J\ s/photon)(7.40 \times 10^{14}\ s^{-1})$
$E = 295{,}000$ J/mol (= 295 kJ/mol)

6.3 (a) E (per atom) $= -Rhc/n^2$
$= (-2.179 \times 10^{-18})/(3^2)$ J/atom
$= -2.421 \times 10^{-19}$ J/atom
(b) E (per mol) $= (-2.421 \times 10^{-19}\ J/atom)(6.022 \times 10^{23}\ atoms/mol)(1\ kJ/10^3\ J)$
$= -145.8$ kJ/mol

6.4 The least energetic line is from the electron transition from $n = 2$ to $n = 1$.
$\Delta E = -Rhc[1/1^2 - 1/2^2]$
$= -(2.179 \times 10^{-18}\ J/atom)(3/4)$
$= -1.634 \times 10^{-18}$ J/atom

The photon emitted thus has $E_{photon} = 1.634 \times 10^{-18}$ J

$\nu = E_{photon}/h$
$= (1.634 \times 10^{-18}\ J)/(6.626 \times 10^{-34}\ J \cdot s)$
$= 2.466 \times 10^{15}\ s^{-1}$

$\lambda = c/\nu = (2.998 \times 10^8\ m/s^{-1})/(2.466 \times 10^{15}\ s^{-1})$
$= 1.216 \times 10^{-7}$ m (or 121.6 nm)

6.5 First, calculate the velocity of the neutron:

$v = [2E/m]^{1/2} = [2(6.21 \times 10^{-21}\ \text{kg} \cdot \text{m}^2\ \text{s}^{-2})/(1.675 \times 10^{-27}\ \text{kg})]^{1/2}$
$= 2720\ \text{m} \cdot \text{s}^{-1}$

Use this value in the de Broglie equation:

$\lambda = h/mv = (6.626 \times 10^{-34}\ \text{kg} \cdot \text{m}^2\ \text{s}^{-2} \cdot \text{s})/(1.675 \times 10^{-27}\ \text{kg})\ (2720\ \text{m s}^{-1})$
$= 1.45 \times 10^{-10}\ \text{m} = 0.145\ \text{nm}$

Review & Check

Applying Chemical Principles: Chemistry of the Sun

1. $\nu = 5.102 \times 10^{14}\ \text{s}^{-1}$

3. For $\lambda = 589.00$ nm, $E = 3.3726 \times 10^{-19}$ J
For $\lambda = 589.59$ nm, $E = 3.3692 \times 10^{-19}$ J
$\Delta E = 3.4 \times 10^{-22}$ J

5. Line F corresponds to a wavelength of 486 nm. Based on Figure 6.10, this line arises from the electron in hydrogen moving from $n = 4$ to $n = 2$.

Study Questions

6.1 (a) Microwaves
(b) Red light
(c) Infrared

6.3 (a) Green light has a higher frequency than amber light
(b) $5.04 \times 10^{14}\ \text{s}^{-1}$

6.5 Frequency = $6.0 \times 10^{14}\ \text{s}^{-1}$; energy per photon = 4.0×10^{-19} J; energy per mol of photons = 2.4×10^5 J

6.7 Frequency = $7.5676 \times 10^{14}\ s^{-1}$; energy per photon = 5.0144×10^{-19} J; 301.97 kJ/mol of photons

6.9 In order of increasing energy: FM station < microwaves < yellow light < x-rays

6.11 Light with a wavelength as long as 600 nm would be sufficient. This is in the visible region.

6.13 (a) The light of shortest wavelength has a wavelength of 253.652 nm.
(b) Frequency = $1.18190 \times 10^{15}\ \text{s}^{-1}$. Energy per photon = 7.83139×10^{-19} J/photon.
(c) The lines at 404 nm (violet) and 436 nm (blue) are in the visible region of the spectrum.

6.15 The color is violet. $n_{\text{initial}} = 6$ and $n_{\text{final}} = 2$

6.17 (a) 10 lines possible
(b) Highest frequency (highest energy), $n = 5$ to $n = 1$
(c) Longest wavelength (lowest energy), $n = 5$ to $n = 4$

6.19 (a) $n = 3$ to $n = 2$
(b) $n = 4$ to $n = 1$. The energy levels are progressively closer at higher levels, so the energy difference from $n = 4$ to $n = 1$ is greater than from $n = 5$ to $n = 2$.

6.21 Wavelength = 102.6 nm and frequency = $2.923 \times 10^{15}\ \text{s}^{-1}$. Light with these properties is in the ultraviolet region.

6.23 Wavelength = 0.29 nm

6.25 The wavelength is 4.8×10^{-25} nm. (Calculated from $\lambda = h/m \cdot v$, where m is the ball's mass in kg and v is the velocity.) To have a wavelength of 5.6×10^{-3} nm, the ball would have to travel at 2.6×10^{-21} m/s.

6.27 (a) $n = 4$, $\ell = 0, 1, 2, 3$
(b) When $\ell = 2$, $m_\ell = -2, -1, 0, 1, 2$
(c) For a $4s$ orbital, $n = 4$, $\ell = 0$, and $m_\ell = 0$
(d) For a $4f$ orbital, $n = 4$, $\ell = 3$, and $m_\ell = -3, -2, -1, 0, 1, 2, 3$

6.29 Set 1: $n = 4$, $\ell = 1$, and $m_\ell = -1$
Set 2: $n = 4$, $\ell = 1$, and $m_\ell = 0$
Set 3: $n = 4$, $\ell = 1$, and $m_\ell = +1$

6.31 Four subshells. (The number of subshells in a shell is always equal to n.)

6.33 (a) ℓ must have a value no greater than $n - 1$.
(b) When $\ell = 0$, m_ℓ can only equal 0.
(c) When $\ell = 0$, m_ℓ can only equal 0.

6.35 (a) None. The quantum number set is not possible. When $\ell = 0$, m_ℓ can only equal 0.
(b) 3 orbitals
(c) 11 orbitals
(d) 1 orbital

6.37 (a) $m_s = 0$ is not possible. m_s may only have values of $\pm 1/2$.

One possible set of quantum numbers: $n = 4$, $\ell = 2$, $m_\ell = 0$, $m_s = +1/2$

(b) m_ℓ cannot equal -3 in this case. If $\ell = 1$, m_ℓ can only be -1, 0, or 1.

One possible set of quantum numbers: $n = 3$, $\ell = 1$, $m_\ell = -1$, $m_s = -1/2$

(c) $\ell = 3$ is not possible in this case. The maximum value of ℓ is $n - 1$.

One possible set of quantum numbers: $n = 3$, $\ell = 2$, $m_\ell = -1$, $m_s = +1/2$

6.39 $2d$ and $3f$ orbitals cannot exist. The $n = 2$ shell consists only of s and p subshells. The $n = 3$ shell consists only of s, p, and d subshells.

6.41 (a) For $2p$: $n = 2$, $\ell = 1$, and $m_\ell = -1$, 0, or $+1$
(b) For $3d$: $n = 3$, $\ell = 2$, and $m_\ell = -2$, -1, 0, $+1$, or $+2$
(c) For $4f$: $n = 4$, $\ell = 3$, and $m_\ell = -3$, -2, -1, 0, $+1$, $+2$, or $+3$

6.43 $4d$

6.45 (a) $2s$ has 0 nodal surfaces that pass through the nucleus ($\ell = 0$).
(b) $5d$ has 2 nodal surfaces that pass through the nucleus ($\ell = 2$).
(c) $5f$ has three nodal surfaces that pass through the nucleus ($\ell = 3$).

6.47 (a) Correct
(b) Incorrect. The intensity of a light beam is independent of frequency and is related to the number of photons of light with a certain energy.
(c) Correct

6.49 Considering only angular nodes (nodal surfaces that pass through the nucleus):

s orbital	0 nodal surfaces through the nucleus
p orbitals	1 nodal surface or plane passing through the nucleus
d orbitals	2 nodal surfaces or planes passing through the nucleus
f orbitals	3 nodal surfaces or planes passing through the nucleus

6.51

ℓ Value	Orbital Type
3	*f*
0	*s*
1	*p*
2	*d*

6.53 Considering only angular nodes (nodal surfaces that pass through the nucleus):

Orbital Type	Number of Orbitals in a Given Subshell	Number of Nodal Surfaces
s	1	0
p	3	1
d	5	2
f	7	3

6.55 (a) Green light
(b) Red light has a wavelength of 680 nm, and green light has a wavelength of 500 nm.
(c) Green light has a higher frequency than red light.

6.57 (a) Wavelength = 0.35 m
(b) Energy = 0.34 J/mol
(c) Violet light (with $\lambda = 420$ nm) has an energy of 280 kJ/mol of photons.
(d) Violet light has an energy (per mol of photons) that is 840,000 times greater than a mole of photons from a cell phone.

6.59 The ionization energy for He^+ is 5248 kJ/mol. This is four times the ionization energy for the H atom.

6.61 $1s < 2s = 2p < 3s = 3p = 3d < 4s$

In the H atom orbitals in the same shell (e.g., $2s$ and $2p$) have the same energy.

6.63 Frequency = 2.836×10^{20} s^{-1} and wavelength = 1.057×10^{-12} m

6.65 260 s or 4.3 min

6.67 (a) Size and energy
(b) ℓ
(c) More
(d) 7 (when $\ell = 3$ these are *f* orbitals)
(e) One orbital
(f) (Left to right) *d*, *s*, and *p*
(g) $\ell = 0, 1, 2, 3, 4$
(h) 16 orbitals (1 *s* orbital, 3 *p* orbitals, 5 *d* orbitals, and 7 *f* orbitals) ($= n^2$)

6.69 Energy = 4.576×10^{-19} J
Frequency = 6.906×10^{14} s^{-1}
Wavelength = 434.1 nm

6.71 The pickle glows because it was made by soaking a cucumber in brine, a concentrated solution of NaCl. The sodium atoms in the pickle are excited by the electric current and release energy as yellow light as they return to the ground state. Excited sodium atoms are the source of the yellow light you see in fireworks and in certain kinds of street lighting.

6.73 (a) $\lambda = 0.0005$ cm = 5 μm
(b) The left side is the higher energy side, and the right side is the lower energy side.
(c) The interaction with O—H requires more energy.

6.75 (c)

6.77 An experiment can be done that shows that the electron can behave as a particle, and another experiment can be done to show that it has wave properties. (However, no single experiment shows both properties of the electron.) The modern view of atomic structure is based on the wave properties of the electron.

6.79 (a) and (b)

6.81 Radiation with a wavelength of 93.8 nm is sufficient to raise the electron to the $n = 6$ quantum level (see Figure 6.10). There should be 15 emission lines involving transitions from $n = 6$ to lower energy levels. (There are five lines for transitions from $n = 6$ to lower levels, four lines for $n = 5$ to lower levels, three for $n = 4$ to lower levels, two lines for $n = 3$ to lower levels, and one line for $n = 2$ to $n = 1$.) Wavelengths for many of the lines are given in Figure 6.10. For example, there will be an emission involving an electron moving from $n = 6$ to $n = 2$ with a wavelength of 410.2 nm.

6.83 (a) Group 7B (IUPAC Group 7); Period 5
(b) $n = 5$, $\ell = 0$, $m_\ell = 0$, $m_s = +1/2$
(c) $\lambda = 8.79 \times 10^{-12}$ m; $\nu = 3.41 \times 10^{19}\ s^{-1}$
(d) (i) $HTcO_4(aq) + NaOH(aq) \rightarrow H_2O(\ell) + NaTcO_4(aq)$
(ii) 8.5×10^{-3} g $NaTcO_4$ produced; 1.8×10^{-3} g NaOH needed
(e) 0.28 mg $NaTcO_4$; 0.00015 M

Chapter 7

Case Study

Metals in Biochemistry and Medicine

1. Fe: $[Ar]3d^64s^2$; Fe^{2+}: $[Ar]3d^6$; Fe^{3+}: $[Ar]3d^5$

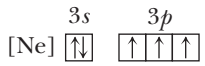
2. Both iron ions are paramagnetic.

3. The slightly larger size of Cu compared to Fe is related to greater electron–electron repulsions.

4. Fe^{2+} is larger than Fe^{3+} and will fit less well into the structure. As a result, some distortion of the ring structure from planarity occurs.

Check Your Understanding

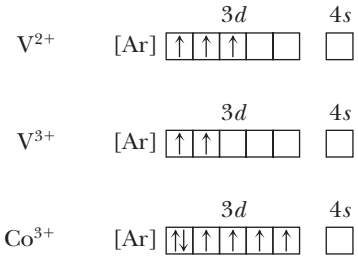
7.1 (a) chlorine (Cl)
(b) $1s^22s^22p^63s^23p^3$



7.2 Calcium has two valence electrons in the 4*s* subshell. Quantum numbers for these two electrons are $n = 4$, $\ell = 0$, $m_\ell = 0$, and $m_s = \pm 1/2$

7.3 Obtain the answers from Table 7.3.

7.4



All three ions are paramagnetic with three, two, and four unpaired electrons, respectively.

7.5 (a) Increasing atomic radius: C < B < Al
(b) Increasing ionization energy: Al < B < C
(c) Carbon is predicted to have the more negative electron attachment enthalpy.

Review & Check

Section 7-1

1. (d) 98

2. (b) $n = 3$, $\ell = 2$, $m_\ell = -1$, and $m_s = -1/2$

Section 7-2

1. (a) the 4*s* orbital fills before the 4*p* orbitals

Section 7-3

1. (c) $3d^{10}4s^24p^4$

2. (c) Ni

Section 7-4

1. (d) Fe^{2+}

2. (c) Co^{3+}

3. (a) Cr

Section 7-5

1. (d) $S^{2-} > Cl^- > K^+$

2. (c) N highest, Si lowest

Section 7-6

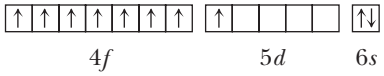
1. (a) MgCl

2. (d) S^{3-}

Applying Chemical Principles: The Not-So-Rare Earths

1. (a) Sm^{3+}: $[Xe]4f^5$
(b) $4\ Sm(s) + 3\ O_2(g) \rightarrow 2\ Sm_2O_3(s)$

3. (a)



(b) The most common oxidation state is +3, corresponding to the loss of the two 6*s* and one 5*d* electrons. The electron configuration of Gd^{3+} is $[Xe]4f^7$.

5. $\nu = 4.90 \times 10^{14}\ s^{-1}$; $E = 3.25 \times 10^{-19}$ J/photon

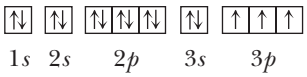
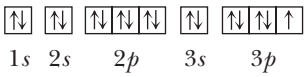
Study Questions

7.1 (a) Phosphorus: $1s^2 2s^2 2p^6 3s^2 3p^3$



The element is in the third period in Group 5A. Therefore, it has five electrons in the third shell.

(b) Chlorine: $1s^2 2s^2 2p^6 3s^2 3p^5$



The element is in the third period and in Group 7A. Therefore, it has seven electrons in the third shell.

7.3 (a) Chromium: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 4s^1$
(b) Iron: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6 4s^2$

7.5 (a) Arsenic: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^3$; $[Ar]3d^{10} 4s^2 4p^3$
(b) Krypton: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$; $[Ar]3d^{10} 4s^2 4p^6 = [Kr]$

7.7 (a) Tantalum: This is the third element in the transition series in the sixth period. Therefore, it has a core equivalent to Xe plus two 6*s* electrons, 14 4*f* electrons, and three electrons in 5*d*: $[Xe]4f^{14} 5d^3 6s^2$
(b) Platinum: This is the eighth element in the transition series in the sixth period. Therefore, it is predicted to have a core equivalent to Xe plus two 6*s* electrons, 14 4*f* electrons, and eight electrons in 5*d*: $[Xe]4f^{14} 5d^8 6s^2$. In reality, its actual configuration (Table 7.3) is $[Xe]4f^{14} 5d^9 6s^1$.

7.9 Americium: $[Rn]5f^7 7s^2$ (see Table 7.3)

7.11 (a) 2
(b) 1
(c) None (because ℓ cannot equal n)

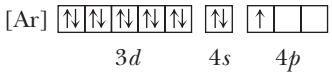
7.13 Magnesium: $1s^2 2s^2 2p^6 3s^2$

Quantum numbers for the two electrons in the 3*s* orbital:

$n = 3$, $\ell = 0$, $m_\ell = 0$, and $m_s = +1/2$

$n = 3$, $\ell = 0$, $m_\ell = 0$, and $m_s = -1/2$

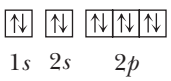
7.15 Gallium: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^1$



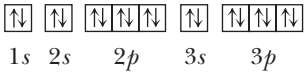
Quantum numbers for the 4*p* electron:

$n = 4$, $\ell = 1$, $m_\ell = -1$, 0, or +1, and $m_s = +\frac{1}{2}$ or $-\frac{1}{2}$

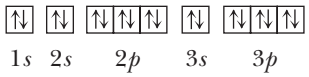
7.17 (a) Mg^{2+} ion



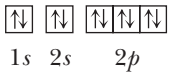
(b) K^+ ion



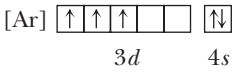
(c) Cl^- ion (Note that both Cl^- and K^+ have the same configuration; both are equivalent to Ar.)



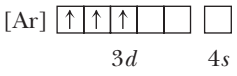
(d) O^{2-} ion



7.19 (a) V (paramagnetic; three unpaired electrons)

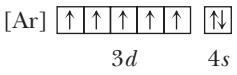


(b) V^{2+} ion (paramagnetic, three unpaired electrons)

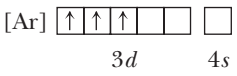


(c) V^{5+} ion. This ion has an electron configuration equivalent to argon, [Ar]. It is diamagnetic with no unpaired electrons.

7.21 (a) Manganese



(b) Mn^{4+}



(c) The 4^+ ion is paramagnetic to the extent of three unpaired electrons.
(d) 3

7.23 Increasing size: C < B < Al < Na < K

7.25 (a) Cl^-
(b) Al
(c) In

7.27 (c)

7.29 (a) Largest radius, Na
(b) Most negative electron attachment enthalpy: O
(c) Ionization energy: Na < Mg < P < O

7.31 (a) Increasing ionization energy: S < O < F. S is less than O because the IE decreases down a group. F is greater than O because IE generally increases across a period.
(b) Largest IE: O. IE decreases down a group.
(c) Most negative electron attachment enthalpy: Cl. Electron attachment enthalpy generally becomes more negative across the periodic table and on ascending a group.
(d) Largest size: O^{2-}. Negative ions are larger than their corresponding neutral atoms. F^- is thus larger than F. O^{2-} and F^- are isoelectronic, but the O^{2-} ion has only eight protons in its nucleus to attract the 10 electrons, whereas the F^- has nine protons, making the O^{2-} ion larger.

7.33 (a) Li (b) K (c) Sc

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

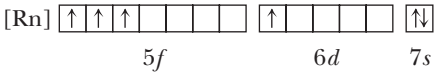
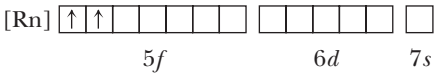
7.35 Identify orbitals that contain electrons: In H and He only the 1*s* orbital is occupied; in Li electrons are present in the 1*s* and 2*s* orbitals. The intensities of peaks in the Li PES are 1 (for the 2*s* electron) and 2 (for the 1*s* electrons).

7.37 (a) Cr configuration: $[Ar]3d^5 4s^1$
Cr^{3+} configuration: $[Ar]3d^3$
(b) Both Cr^{2+} and Cr^{3+} are paramagnetic
(c) The radii are similar (radius for Al^{3+} = 57 nm), which is the reason that Cr^{3+} ions are sometimes found in solid Al_2O_3 in place of Al^{3+}.

7.39 Uranium configuration: $[Rn]5f^3 6d^1 7s^2$



Uranium(IV) ion, U^{4+}: $[Rn]5f^2$

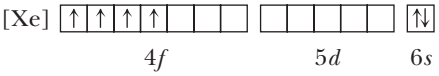


Both U and U^{4+} are paramagnetic.

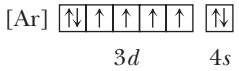
7.41 (a) Atomic number = 20
(b) Total number of *s* electrons = 8
(c) Total number of *p* electrons = 12
(d) Total number of *d* electrons = 0
(e) The element is Ca, calcium, a metal.

7.43 (a) Valid. Possible elements are Li and Be.
(b) Not valid. The maximum value of ℓ is $(n - 1)$.
(c) Valid. Possible elements are B through Ne.
(d) Valid. Possible elements are Y through Cd.

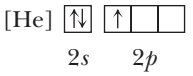
7.45 (a) Neodymium, Nd: $[Xe]4f^4 6s^2$ (Table 7.3)



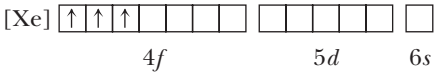
Iron, Fe: $[Ar]3d^6 4s^2$



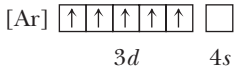
Boron, B: $[He]2s^2 2p^1$



(b) All three elements have unpaired electrons and so should be paramagnetic.
(c) Neodymium(III) ion, Nd^{3+}: $[Xe]4f^3$



Iron(III) ion, Fe^{3+}: $[Ar]3d^5$



Both neodymium(III) and iron(III) have unpaired electrons and are paramagnetic.

7.47 K < Ca < Si < P

7.49 (a) Metal
(b) B
(c) A
(d) A
(e) Rb_2Se

7.51 In^{4+}: Indium has three outer shell electrons and so is unlikely to form a 4^+ ion.

Fe^{6+}: Although iron has eight electrons in its 3*d* and 4*s* orbitals, ions with a 6^+ charge are highly unlikely. The ionization energy is too large.

Sn^{5+}: Tin has four outer shell electrons and so is unlikely to form a 5^+ ion.

7.53 (a) Se
(b) Br^-
(c) Na
(d) N
(e) N^{3-}

7.55 (a) Na
(b) C
(c) Na < Al < B < C

7.57 (a) Cobalt
(b) Paramagnetic
(c) Four unpaired electrons

7.59 (a) metal
(b) B
(c) A
(d) B
(e) A
(f) AB_2 or SrI_2

7.61 (a) 0.421 g
(b) Paramagnetic; two unpaired electrons
(c) 99.8 mg; the nickel powder is paramagnetic and will stick to a magnet.

7.63 Li has three electrons ($1s^2 2s^1$) and Li^+ has only two electrons ($1s^2$). The ion is smaller than the atom because there are only two electrons to be held by three protons in the ion. Also, an electron in a larger orbital has been removed. Fluorine atoms have nine electrons and nine protons ($1s^2 2s^2 2p^5$). The anion, F^-, has one additional electron, which means that 10 electrons must be held by only nine protons, and so the ion is larger than the atom.

7.65 (a) The electron removed from Al is in the 3*p* orbital, which has a less negative energy than the 3*s* orbital from which the electron is removed in Mg. See the plot of orbital energies in *A Closer Look: Orbital Energies, Z*, and Electron Configurations*, page 262.
(b) The electron removed from S is one of a pair. Electron-electron repulsion lowers the energy required to remove the electron. (The 3*p* electrons of P are not paired.)

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

7.67 The most stable configuration is (d) (parallel spins in different orbitals, according to Hund's rule.) Configuration (b) is less stable than (c) due to repulsion of the two electrons in the same orbital. Configuration (a) is not an acceptable possibility; two electrons cannot have the same set of quantum numbers.

7.69 $K\ (1s^2 2s^2 2p^6 3s^2 3p^6 4s^1) \rightarrow K^+(1s^2 2s^2 2p^6 3s^2 3p^6)$

$K^+\ (1s^2 2s^2 2p^6 3s^2 3p^6) \rightarrow K^{2+}(1s^2 2s^2 2p^6 3s^2 3p^5)$

The first ionization is for the removal of an electron from the valence shell of electrons. The second electron, however, is removed from the 3*p* subshell. This subshell is significantly lower in energy than the 4*s* subshell, and considerably more energy is required to remove this second electron.

7.71 (a) In going from one element to the next across the period, the effective nuclear charge increases slightly and the attraction between the nucleus and the electrons increases.
(b) The size of fourth period transition elements, for example, is a reflection of the size of the 4*s* orbital. As *d* electrons are added across the series, protons are added to the nucleus. Adding protons should lead to a decreased atom size, but the effect of the protons is balanced by repulsions of the 3*d* electrons and 4*s* electrons, and the atom size is changed little.

7.73 Among the arguments for a compound composed of Mg^{2+} and O^{2-} are the following:
(a) Chemical experience suggests that all Group 2A elements form 2^+ cations, and that oxygen is typically the O^{2-} ion in its compounds.
(b) Other alkaline earth elements form oxides such as BeO, CaO, and BaO.

A possible experiment is to measure the melting point of the compound. An ionic compound such as NaF (with ions having 1^+ and 1^- charges) melts at 990 °C, whereas a compound analogous to MgO, CaO, melts at a much higher temperature (2580 °C).

7.75 (a) The effective nuclear charge increases, causing the valence orbital energies to become more negative on moving across the period.
(b) As the valence orbital energies become more negative, it is increasingly difficult to remove an electron from the atom, and the IE increases. Toward the end of the period, the orbital energies have become so negative that removing an electron requires significant energy. Instead, the effective nuclear charge has reached the point that the atom forms a negative ion, in line with the more negative electron attachment enthalpy for elements on the right side of the periodic table.
(c) The valence orbital energies are in the order:

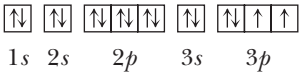
Li (−520.0 kJ) < Be (−899.3 kJ) > B (−800.8 kJ) < C (−1029 kJ)

This means it is more difficult to remove an electron from Be than from either Li or B. The energy is more negative for C than for B, so it is more difficult to remove an electron from C than from B.

7.77 The size declines across this series of elements while their mass increases. Thus, the mass per volume, the density, increases.

7.79 (a) Element 113: $[Rn]5f^{14}6d^{10}7s^27p^1$
Element 115: $[Rn]5f^{14}6d^{10}7s^27p^3$
(b) Element 113 is in Group 3A (with elements such as boron and aluminum), and element 115 is in Group 5A (with elements such as nitrogen and phosphorus).
(c) Americium ($Z = 95$) + argon ($Z = 18$) = element 113

7.81 (a) Sulfur electron configuration



(b) One possible set of quantum numbers for a 3*p* electron is:
$n = 3$, $\ell = 1$, $m_\ell = 1$, and $m_s = +1/2$
(c) S has the smallest ionization energy and O has the smallest radius.
(d) S is smaller than the S^{2-} ion.
(e) 584 g SCl_2
(f) 10.0 g of SCl_2 is the limiting reactant, and 11.6 g of $SOCl_2$ can be produced.
(g) $\Delta_f H°[SCl_2(g)] = -17.6$ kJ/mol

7.83 (a) Z* for F is 5.20; Z* for Ne is 5.85. The effective nuclear charge increases from O to F to Ne. As the effective nuclear charge increases, the atomic radius decreases, and the first ionization energy increases.
(b) Z* for a 3*d* electron in Mn is 5.6; for a 4*s* electron it is only 3.6. The effective nuclear charge experienced by a 4*s* electron is much smaller than that experienced by a 3*d* electron. A 4*s* electron in Mn is thus more easily removed.

Chapter 8

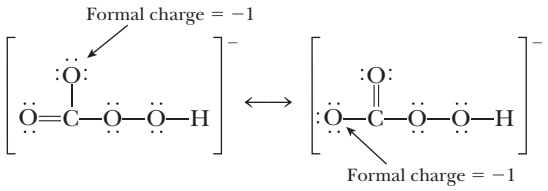
Case Studies

Free Radicals, Atmospheric Chemistry, and Hair Dyes

1. 18 valence electrons

All atoms have a formal charge of zero. There are no equivalent resonance structures.

2. 30 valence electrons



All atoms have zero formal charge except for those indicated.

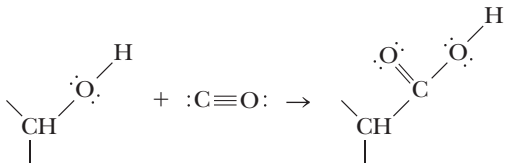
Ibuprofen, a Study in Green Chemistry

1. The Lewis structures for the key portions of the molecules where the reaction takes place are the following:



Bonds broken: 1 C—O and 1 C≡O

(1 mol C—O/1 mol-rxn)(358 kJ/mol C—O) + (1 mol C≡O/1 mol-rxn)(1046 kJ/mol C≡O) = 1404 kJ/mol-rxn

Bonds formed: 1 C—C, 1 C═O, and 1 C—O

(1 mol C—C/1 mol-rxn)(346 kJ/mol C—C) + (1 mol C═O/1 mol-rxn)(745 kJ/mol C═O) + (1 mol C—O/1 mol-rxn)(358 kJ/mol C—O) = 1449 kJ/mol-rxn

$\Delta_r H° \approx$ 1404 kJ/mol-rxn − 1449 kJ/mol-rxn = −45 kJ/mol-rxn

The reaction is thus predicted to be exothermic.

2. All of the atoms in ibuprofen have a formal charge of zero.

3. The most polar bond in the molecule is the O—H bond.

4. The molecule is not symmetrical and so is polar.

5. The shortest bond in the molecule is the O—H bond.

6. The C═O bond has the highest bond order. The C═C bonds in the ring have an order of 1.5.

7. Yes, there are 120° bond angles present: the bond angles around the C atoms in the ring and those around the C atom in the $—CO_2H$ group are all 120°. There are no 180° angles in this molecule.

8. There is one acid group in ibuprofen ($—CO_2H$), therefore 1 mol of ibuprofen will react with 1 mol of NaOH.

200. mg ibuprofen (1 g/1000 mg)(1 mol ibuprofen/206.3 g ibuprofen)(1 mol NaOH/1 mol ibuprofen)(1 L/0.0259 mol NaOH)(1000 mL/1 L) = 37.4 mL

Therefore 37.4 mL of the NaOH solution would be required.

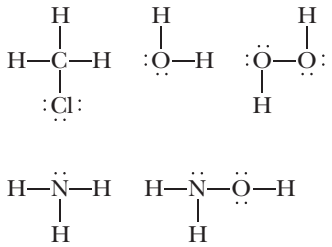
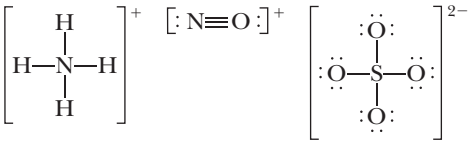
8.1

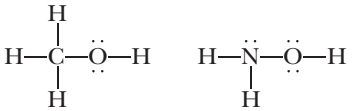


8.2 :C≡O:

8.3



8.4

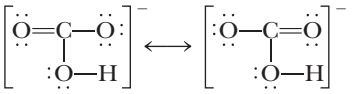


methanol hydroxylamine

8.5 (a) CN^- : formal charge on C is −1; formal charge on N is 0.

(b) SO_3^{2-}: formal charge on S is +1; formal charge on each O is −1.

8.6 Resonance structures for the HCO_3^- ion:



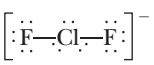
(a) No. Three resonance structures are needed in the description of CO_3^{2-}; only two are needed to describe HCO_3^-.

(b) In each resonance structure: carbon's formal charge is 0; the oxygen of the —OH group and the double-bonded oxygen have a formal charge of zero; the singly bonded oxygen has a formal charge of −1. The average formal charge on the latter two oxygen atoms is $-\frac{1}{2}$. In the carbonate ion, each of the three oxygen atoms has an average formal charge of $-\frac{2}{3}$.

(c) H^+ would be expected to add to one of the oxygens with a negative formal charge; that is, one of the oxygens with formal charge of $-\frac{1}{2}$ in this structure.

8.7

ClF_2^+, 2 bond pairs and 2 lone pairs.



ClF_2^-, 2 bond pairs and 3 lone pairs.

8.8 Tetrahedral geometry around carbon. The Cl—C—Cl bond angle will be close to 109.5°.

8.9 For each species, the electron-pair geometry and the molecular shape are the same. BF_3: trigonal-planar; BF_4^-: tetrahedral. Adding F^- to BF_3 adds an electron pair to the central atom and changes the shape.

8.10 The electron-pair geometry around I is trigonal-bipyramidal. The molecular geometry of the ion is linear.

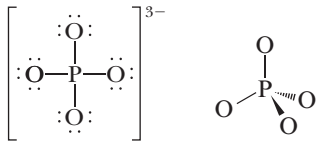
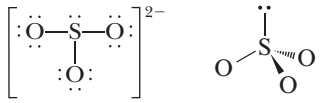
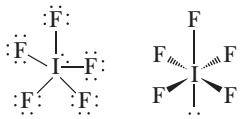
8.11 (a) In PO_4^{3-}, there is tetrahedral electron-pair geometry. The molecular geometry is also tetrahedral.



(b) In SO_3^{2-}, there is tetrahedral electron-pair geometry. The molecular geometry is trigonal-pyramidal.



(c) In IF_5, there is octahedral electron-pair geometry. The molecular geometry is square-pyramidal.

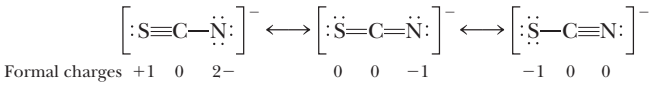


8.12 (a) The H atom is the positive pole in each case. H—F ($\Delta\chi = 1.8$) is more polar than H—I ($\Delta\chi = 0.5$).

(b) The B atom is the positive pole in each case. B—F ($\Delta\chi = 2.0$) is more polar than B—C ($\Delta\chi = 0.5$).

(c) C—Si ($\Delta\chi = 0.6$) is more polar than C—S ($\Delta\chi = 0.1$). In C—Si, C is the negative pole, and Si is the positive pole. In C—S, S is the negative pole, and C the positive pole.

8.13 16 valence electrons

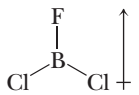


Formal charge considerations favor the middle structure because it has less formal charge than the left structure and, unlike the right structure, it has the negative formal charge on the most electronegative atom in the ion.

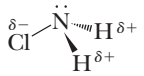
Bond polarity: For the C—N bond, $\Delta\chi = 0.5$, so this bond is polar and should have a partially positive C and a partially negative N. For the C—S bond, $\Delta\chi = 0.1$, so this bond should be only slightly polar with a partially positive C and a partially negative S.

Comparison of formal charge and bond polarity: The bonding in SCN^- will be closest to the middle resonance structure with a smaller contribution of the resonance structure on the right. From this we conclude that both N and S will have a negative formal charge, with N having the more negative value. The polarities of the C—N and C—S bonds match this description, with N and S being the negative end of each polar bond.

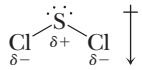
8.14 (a) $BFCl_2$, polar, negative side is the F atom because F is the most electronegative atom in the molecule.



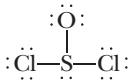
(b) NH_2Cl, polar, negative side is the Cl atom.



(c) SCl_2, polar, Cl atoms are on the negative side.



8.15 (a)



Formal charges: S = +1, O = −1, Cl = 0

(b) Geometry: trigonal-pyramidal. The molecule is polar. The positive charge is on sulfur, the negative charge on oxygen.

8.16 $CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(g)$

Break 4 C—H bonds and 2 O=O bonds:
(4 mol)(413 kJ/mol) + (2 mol)(498 kJ/mol) = 2648 kJ

Make 2 C=O bonds and 4 H—O bonds:
(2 mol)(803 kJ/mol) + (4 mol)(463 kJ/mol) = 3458 kJ

$\Delta_r H° = 2648\ kJ - 3458\ kJ = -810$ kJ/mol-rxn
(value calculated using enthalpies of formation = −802 kJ/mol-rxn)

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

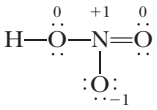
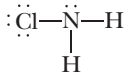
(d) The central N atom is +1, one of the O atoms is −1, and the other two O atoms and the H atom are all 0.



8.17 (a) Electron-pair geometry around N is tetrahedral. Molecular geometry is trigonal-pyramidal.



(b) Electron-pair geometry around O is tetrahedral. Molecular geometry is bent.

(c) Electron-pair geometry around C is linear. Molecular geometry is linear.

(d) Electron-pair geometry around O is tetrahedral. The molecular geometry is bent.

8.19 (a) Electron-pair geometry around C is linear. Molecular geometry is linear.

(b) Electron-pair geometry around N is trigonal-planar. Molecular geometry is bent.

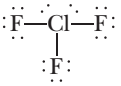
(c) Electron-pair geometry around O is trigonal-planar. Molecular geometry is bent.

(d) Electron-pair geometry around Cl atom is tetrahedral. Molecular geometry is bent.

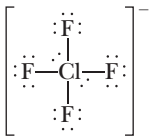
All have two atoms attached to the central atom. As the bond and lone pairs vary, the electron-pair geometries vary from linear to tetrahedral, and the molecular geometries vary from linear to bent.

8.21 (a) Electron-pair geometry around Cl is trigonal-bipyramidal. Molecular geometry is linear.

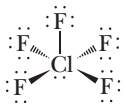
(b) Electron-pair geometry around Cl is trigonal-bipyramidal. Molecular geometry is T-shaped.



(c) Electron-pair geometry around Cl is octahedral. Molecular geometry is square-planar.



(d) Electron-pair geometry around Cl is octahedral. Molecular geometry is a square-pyramidal.



8.23 (a) Ideal O—S—O angle = 120°
(b) 120°
(c) 120°
(d) H—C—H = 109° and C—C—N angle = 180°

8.25 1 = 120°; 2 = 109°; 3 = 120°; 4 = 109°; 5 = 109°

The chain cannot be linear because the first two carbon atoms in the chain have bond angles of 109° and the final one has a bond angle of 120°. These bond angles do not lead to a linear chain.

8.27

CO is more polar

PCl is more polar

BO is more polar

BF is more polar

8.29 (a) CH and CO bonds are polar.
(b) The CO bond is most polar, and O is the most negative atom.

8.31 (a) OH^-: The formal charge on O is −1 and on H it is 0.
(b) BH_4^-: Even though the formal charge on B is −1 and on H is 0, H is slightly more electronegative than B. The four H atoms are therefore more likely to bear the −1 charge of the ion. The BH bonds are polar with the H atom the negative end.
(c) The CH and CO bonds are all polar (but the C—C bond is not). The negative charge in the CO bonds lies on the O atoms.

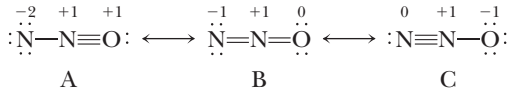
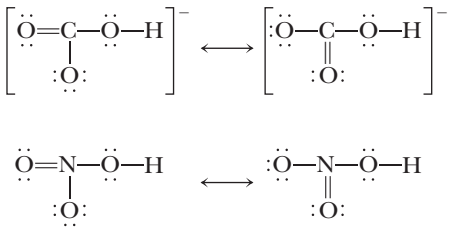
8.33 Structure C is most reasonable. The charges are as small as possible, and the negative charge resides on the more electronegative atom.



A B C

8.35 Lewis structures:



(a) These species are isoelectronic.
(b) Each has two major resonance structures.
(c) In HCO_3^-, the H, C, and O attached to the H all have a formal charge of 0. Each of the other oxygen atoms has a formal charge of −1/2.

In HNO_3, the same formal charges are present as in HCO_3^- except that the central N has a formal charge of +1.
(d) HNO_3 is much more acidic than HCO_3^-. This is due, in part, to simple electrostatics. It is much easier to remove a positively charge species (H^+) from a neutral species (HNO_3) than from a negatively charged one (HCO_3^-).

8.37 (a) 

(b) If an H^+ ion were to attack NO_2^-, it would attach to an O atom because the O atoms bear the negative charge in this ion.

(c) 
The structure on the left is strongly favored because all of the atoms have zero formal charge, whereas the structure on the right has a −1 formal charge on one oxygen (*left*) and a +1 formal charge on the other (*right*).

8.39 (i) The most polar bonds are in H_2O (because O and H have the largest difference in electronegativity).
(ii) Not polar: CO_2 and CCl_4
(iii) The F atom is more negatively charged.

8.41 (a) $BeCl_2$, nonpolar linear molecule
(b) HBF_2, polar trigonal-planar molecule with F atoms on the negative end of the dipole and the H atom on the positive end.
(c) CH_3Cl, polar tetrahedral molecule. The Cl atom is on the negative end of the dipole and the three H atoms are on the positive side of the molecule.
(d) SO_3, a nonpolar trigonal-planar molecule

8.43 (a) Two C—H bonds, bond order is 1; 1 C=O bond, bond order is 2.
(b) Three S—O single bonds, bond order is 1.
(c) Two nitrogen–oxygen double bonds, bond order is 2.
(d) One N=O double bond, bond order is 2; one N—Cl bond, bond order is 1.

8.45 (a) B—Cl
(b) C—O
(c) P—O
(d) C=O

8.47 NO bond orders: 2 in NO_2^+, 1.5 in NO_2^-; 1.33 in NO_3^-. The NO bond is longest in NO_3^- and shortest in NO_2^+.

8.49 The CO bond in carbon monoxide is a triple bond, so it is both shorter and stronger than the CO double bond in H_2CO.

8.51 Using bond dissociation enthalpy data, $\Delta_r H° \approx -44$ kJ/mol-rxn. Using $\Delta_f H°$ data, $\Delta_r H° = -45.9$ kJ/mol-rxn.

8.53 $\Delta_r H = -126$ kJ

8.55 O—F bond dissociation energy = 192 kJ/mol

8.57

Element	Number of Valence Electrons
Li	1
Ti	4
Zn	2
Si	4
Cl	**7**

8.59 SeF_4, BrF_4^-, XeF_4

8.61 
Bond order = 3/2

8.63 To estimate the enthalpy change, we need bond dissociation enthalpies for the following bonds: O=O, H—H, and H—O.

ΔH to break bonds ≈ 498 kJ (for O=O) + 2 × 436 kJ (for H—H) = +1370 kJ

ΔH evolved when bonds are made ≈ 4 × 463 kJ (for O—H) = −1852 kJ

$\Delta_r H \approx -482$ kJ

8.65 All the species in the series have 16 valence electrons and all are linear.

(a) 

(b) 
(c) 
Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

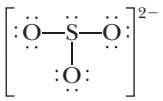
8.67 The N—O bonds in NO_2^- have a bond order of 1.5, whereas in NO_2^+ the bond order is 2. The shorter bonds (110 pm) are the NO bonds with the higher bond order (in NO_2^+), whereas the longer bonds (124 pm) in NO_2^- have a lower bond order.

8.69 The F—Cl—F bond angle in ClF_2^+, which has a tetrahedral electron-pair geometry, is approximately 109°.

The ClF_2^- ion has a trigonal-bipyramidal electron-pair geometry with F atoms in the axial positions and the lone pairs in the equatorial positions. Therefore, the F—C—F angle is 180°.

The anion ClF_2^- has the greater bond angle.

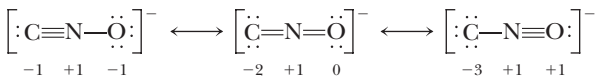
8.71 An H^+ ion will attach to an O atom of SO_3^{2-} and not to the S atom. The O atoms each have a formal charge of −1, whereas the S atom formal charge is +1.



8.73 (a) Calculation from bond dissociation enthalpies: $\Delta_r H° = -1070$ kJ/mol-rxn; $\Delta H° = -535$ kJ/mol CH_3OH

(b) Calculation from thermochemical data: $\Delta_r H° = -1352.3$ kJ/mol-rxn; $\Delta H° = -676$ kJ/mol CH_3OH

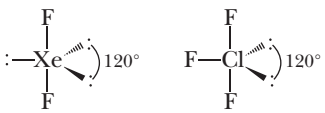
8.75 (a)



(b) The first resonance structure is the most reasonable because oxygen, the most electronegative atom, has a negative formal charge, and the unfavorable negative charge on the least electronegative atom, carbon, is smallest.

(c) This species is so unstable because carbon, the least electronegative element in the ion, has a negative formal charge. In addition, all three resonance structures have an unfavorable charge distribution.

8.77



(a) XeF_2 has three lone pairs around the Xe atom. The electron-pair geometry is trigonal-bipyramidal. Because lone pairs require more space than bond pairs, it is better to place the lone pairs in the equator of the bipyramid where the angles between them are 120°.

(b) Like XeF_2, ClF_3 has a trigonal-bipyramidal electron-pair geometry, but with only two lone pairs around the Cl. These are again placed in the equatorial plane where the angle between them is 120°.

8.79 (a) Angle 1 = 109°; angle 2 = 120°; angle 3 = 109°; angle 4 = 109°; and angle 5 = 109°

(b) The O—H bond is the most polar bond.

8.81 $\Delta_r H = +146 \text{ kJ} = 2\,(\Delta H_{C-N}) + \Delta H_{C=O} - [\Delta H_{N-N} + \Delta H_{C\equiv O}]$

8.83 (a) Two C—H bonds and one O=O are broken and two O—C bonds and two H—O bonds are made in the reaction. $\Delta_r H = -318$ kJ. The reaction is exothermic.

(b) Both hydroxyacetone and acetone are polar.

(c) The O—H hydrogen atoms are the most positive in dihydroxyacetone.

8.85 (a) The C=C bond is stronger than the C—C bond.

(b) The C—C single bond is longer than the C=C double bond.

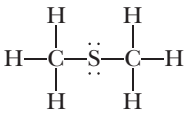
(c) Ethylene is nonpolar, whereas acrolein is polar.

(d) The reaction is exothermic ($\Delta_r H = -45$ kJ).

8.87 $\Delta_r H = -211$ kJ

8.89 Methanol is a polar solvent. Methanol contains two bonds of significant polarity, the C—O bond and the O—H bond. The C—O—H atoms are in a bent configuration, leading to a polar molecule. Toluene contains only carbon and hydrogen atoms, which have similar electronegativites and which are arranged in tetrahedral or trigonal planar geometries, leading to a molecule that is largely nonpolar.

8.91 (a)



The bond angles are all approximately 109°.

(b) The sulfur atom should have a slight partial negative charge, and the carbons should have slight partial positive charges. The molecule has a bent shape and is polar.

(c) 1.6×10^{18} molecules

8.93 (a) $P_4 + 6\ Cl_2 \rightarrow 4\ PCl_3$

(b) $\Delta_r H = -1206.9$ kJ/mol-rxn

(c) Bonds broken: 6 mol P—P, 6 mol Cl—Cl
Bonds formed: 12 mol P—Cl
$\Delta H_{P-Cl} = 322$ kJ/mol; the value in Table 8.9 is 326 kJ/mol

8.95 (a) Odd electron molecules: BrO (13 electrons)

(b) $Br_2(g) \rightarrow 2\ Br(g)$ $\quad \Delta_r H = +193$ kJ
$2\ Br(g) + O_2(g) \rightarrow 2\ BrO(g)$ $\quad \Delta_r H = +96$ kJ
$BrO(g) + H_2O(g) \rightarrow HOBr(g) + OH(g)$ $\quad \Delta_r H = 0$ kJ

(c) $\Delta_f H\ [HOBr(g)] = -101$ kJ/mol

(d) The reactions in part (b) are endothermic (or thermal-neutral for the third reaction), and the enthalpy of formation in part (c) is exothermic.

Case Study

Green Chemistry, Safe Dyes, and Molecular Orbitals

1. C_8H_4BrNO
2. The energy per photon is inversely proportional to wavelength. The light absorbed by butter yellow has a smaller wavelength than that absorbed by nitrated butter yellow; therefore, butter yellow absorbs higher energy light than does nitrated butter yellow.
3. Tyrian purple: 9

   Nitrated butter yellow: 8

Check Your Understanding

9.1 The carbon and nitrogen atoms in CH_3NH_2 are sp^3 hybridized. The C—H bonds arise from overlap of carbon sp^3 orbitals and hydrogen 1*s* orbitals. The bond between C and N is formed by overlap of sp^3 orbitals from these atoms. Overlap of nitrogen sp^3 and hydrogen 1*s* orbitals gives the two N—H bonds, and there is a lone pair in the remaining sp^3 orbital on nitrogen.

9.2 (a) sp^3
(b) (from left to right) sp^2, sp^2, sp^3
(c) sp^2

9.3 The two CH_3 carbon atoms are sp^3 hybridized, and the center carbon atom is sp^2 hybridized. For each of the carbon atoms in the methyl groups, the sp^3 orbitals overlap with hydrogen 1*s* orbitals to form the three C—H bonds, and the fourth sp^3 orbital overlaps with an sp^2 orbital on the central carbon atom, forming a carbon–carbon sigma bond. Overlap of an sp^2 orbital on the central carbon and an oxygen sp^2 orbital gives the sigma bond between these elements. The π bond between carbon and oxygen arises by overlap of a *p* orbital from each element.

9.4 H_2^+: $(\sigma_{1s})^1$ The ion has a bond order of ½ and is expected to exist. A bond order of ½ is predicted for He_2^+ and H_2^-, both of which are predicted to have electron configurations $(\sigma_{1s})^2(\sigma^*_{1s})^1$.

9.5 Li_2^- is predicted to have an electron configuration $(\sigma_{1s})^2(\sigma^*_{1s})^2(\sigma_{2s})^2(\sigma^*_{2s})^1$ and a bond order of ½, the positive value implying that the ion might exist.

9.6 O_2^+: [core electrons] $(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^1$. The bond order is 2.5. The ion is paramagnetic with one unpaired electron.

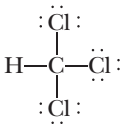
Applying Chemical Principles: Probing Molecules with Photoelectron Spectroscopy

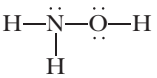
1. Metal
3. σ_{2p}
5. The 15.6 eV and 16.7 eV ejected electrons came from bonding orbitals. Removing an electron from a bonding orbital weakens the bond and thus results in a longer bond length. The 18.6 eV ejected electron comes from an antibonding orbital.

Study Questions

9.1 The electron-pair and molecular geometry of $CHCl_3$ are both tetrahedral. Each C—Cl bond is formed by the overlap of an sp^3 hybrid orbital on the C atom with a 3*p* orbital on a Cl atom to form a sigma bond. A C—H sigma bond is formed by the overlap of an sp^3 hybrid orbital on the C atom with an H atom 1*s* orbital.

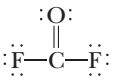


9.3



Both the N and the O are sp^3 hybridized. One of the sp^3 orbitals on the N overlaps with one of the sp^3 hybrid orbitals on the O.

9.5



The electron-pair and molecular geometries are both trigonal-planar. The carbon atom is sp^2 hybridized. The σ bond between the C and O is formed by the overlap of an sp^2 hybrid orbital on C with an sp^2 hybrid orbital on O. The π bond is formed by the overlap of a 2*p* orbital on C with a 2*p* orbital on O.

9.7

	Electron-Pair Geometry	Molecular Geometry	Hybrid Orbital Set
(a)	Trigonal-planar	Trigonal-planar	sp^2
(b)	Linear	Linear	sp
(c)	Tetrahedral	Tetrahedral	sp^3
(d)	Trigonal-planar	Trigonal-planar	sp^2

9.9 (a) C, sp^3; O, sp^3
(b) CH_3, sp^3; middle C, sp^2; CH_2, sp^2
(c) CH_2, sp^3; CO_2H, sp^2; N, sp^3

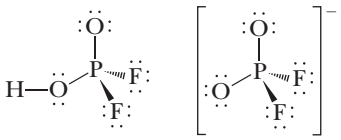
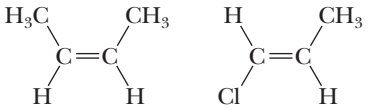
9.11 There are 32 valence electrons in both HPO_2F_2 and its anion. Both have a tetrahedral molecular geometry, so the P atom in both is sp^3 hybridized.



9.13 The C atom is sp^2 hybridized. Two of the sp^2 hybrid orbitals are used to form C—Cl σ bonds, and the third is used to form the C—O σ bond. The p orbital not used in the C atom hybrid orbitals is used to form the CO pi bond.

9.15 The electron-pair geometry around S is tetrahedral, and the molecular geometry is trigonal-pyramidal. The S atom is sp^3 hybridized.

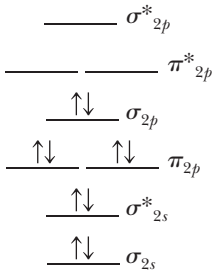
9.17



cis isomer *trans* isomer

9.19 H_2^+ ion: $(\sigma_{1s})^1$. Bond order is 0.5. The bond in H_2^+ is weaker than in H_2 (bond order = 1).

9.21 MO diagram for C_2^{2-} ion



The ion has 10 valence electrons (isoelectronic with N_2). There are one net σ bond and two net π bonds, for a bond order of 3. The bond order increases by 1 on going from C_2 to C_2^{2-}. The ion is not paramagnetic.

9.23 O_2: (core electrons)$(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^2$
O_2^{2-}: (core electrons)$(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^4$
(a) O_2 is paramagnetic; O_2^{2-} is diamagnetic.
(b) O_2 has one net σ bond and one net π bond. O_2^{2-} has one net σ bond.
(c) O_2 bond order = 2; O_2^{2-} bond order = 1
(d) The bond length in O_2 is shorter than that in O_2^{2-}.

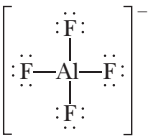
9.25 Shortest, N_2; longest, Li_2

9.27 (a) ClO has 13 valence electrons

$$[\text{core}](\sigma_s)^2(\sigma^*_s)^2(\pi_p)^4(\sigma_p)^2(\pi^*_p)^3$$

(b) π^*_p
(c) Paramagnetic
(d) There are net 1 σ bond and 0.5 π bonds; bond order is 1.5.

9.29



The electron pair and molecular geometries are both tetrahedral. The Al atom is sp^3 hybridized, so the Al—F bonds are formed by overlap of an Al sp^3 orbital with a p orbital on each F atom. The formal charge on each of the fluorines is 0, and that on the Al is −1. This is not a reasonable charge distribution because the less electronegative atom, aluminum, has the negative charge.

9.31

The electron-pair geometry is trigonal-planar. The molecular geometry is bent (or angular). The O—N—O angle will be about 120°, the average N—O bond order is 3/2, and the N atom is sp^2 hybridized.

9.33 The resonance structures of N_2O, with formal charges, are shown here.

A B C

The central N atom is sp hybridized in all structures. The two sp hybrid orbitals on the central N atom are used to form N—N and N—O σ bonds. The two p orbitals not used in the N atom hybridization are used to form the required π bonds.

9.35 (a) All three have the formula C_2H_4O. (These are isomers because they have the same formula. However, they have different structures.)
(b) *Ethylene oxide:* Both C atoms are sp^3 hybridized.
Acetaldehyde: The CH_3 carbon atom has sp^3 hybridization, and the other C atom is sp^2 hybridized.
Vinyl alcohol: Both C atoms are sp^2 hybridized.
(c) *Ethylene oxide:* 109°
Acetaldehyde: 109°
Vinyl alcohol: 120°
(d) All are polar.
(e) Acetaldehyde has the strongest CO bond, and vinyl alcohol has the strongest C—C bond.

9.37 (a) CH_3 carbon atom: sp^3
C=N carbon atom: sp^2
N atom: sp^2
(b) C—N—O bond angle = 120°

9.39 (a) C(1) = sp^2; O(2) = sp^3; N(3) = sp^3; C(4) = sp^3; P(5) = sp^3
(b) Angle A = 120°; angle B = 109°; angle C = 109°; angle D = 109°
(c) The P—O and O—H bonds are most polar ($\Delta\chi$ = 1.3).

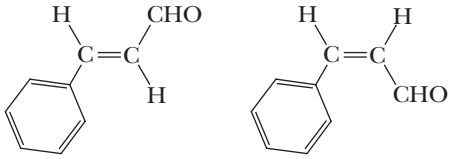
9.41 (a) C═O bond is most polar.
(b) 18 σ bonds and five π bonds
(c)



trans isomer *cis* isomer

(d) All C atoms are sp^2 hybridized.
(e) All bond angles are 120°.

9.43 (a) The peroxide ion has a bond order of 1.

(b) [Core electrons]$(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^4$
This configuration also leads to a bond order of 1.
(c) Both theories lead to a diamagnetic ion with a bond order of 1.

9.45 Paramagnetic diatomic molecules: B_2 and O_2

Bond order of 1: Li_2, B_2, F_2; bond order of 2: C_2 and O_2; highest bond order: N_2

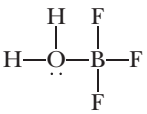
9.47 CN has nine valence electrons.

[core electrons]$(\sigma_{2s})^2(\sigma^*_{2s})^2(\pi_{2p})^4(\sigma_{2p})^1$

(a) HOMO, σ_{2p}
(b, c) Bond order = 2.5 (0.5 σ bond and 2 π bonds)
(d) Paramagnetic

9.49 (a) All C atoms are sp^3 hybridized.
(b) About 109°
(c) Polar
(d) The six-membered ring cannot be planar, owing to the tetrahedral C atoms of the ring. The bond angles are all 109°.

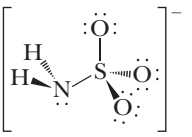
9.51 (a) The geometry about the boron atom is trigonal-planar in BF_3 but tetrahedral in $H_3N—BF_3$.
(b) Boron is sp^2 hybridized in BF_3 but sp^3 hybridized in $H_3N—BF_3$.
(c) The ammonia molecule is polar with the N atom partially negative. While the BF_3 molecule is nonpolar overall, each of the B—F bonds is polarized such that the B has a partial positive charge. The partially negative N in NH_3 is attracted to the partially positive B in BF_3.
(d) One of the lone pairs on the oxygen of H_2O can form a coordinate covalent bond with the B in BF_3. The resulting compound would be (the lone pairs on the F's not shown):



9.53 (a) NH_2^-: electron-pair geometry = tetrahedral, molecular geometry = bent, hybridization of N = sp^3

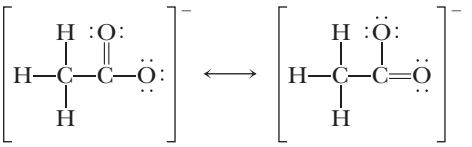
SO_3: electron-pair geometry = molecular geometry = trigonal-planar, hybridization of S = sp^2

(b)



The bond angles around the N and the S are all approximately 109°.
(c) The N does not undergo any change in its hybridization; the S changes from sp^2 to sp^3.
(d) The SO_3 is the acceptor of an electron pair in this reaction. The electrostatic potential map confirms this to be reasonable because the sulfur has a partial positive charge.

9.55



Hybridization of C in $—CO_2^-$ is sp^2

C—C bond: overlap of sp^2 hybrid orbital on the carbon of $—CO_2^-$ with sp^3 hybrid orbital on the other C.

C—O σ bond of C═O double bond: overlap of sp^2 hybrid orbital on C with sp^2 hybrid orbital on O

C—O π bond of C═O double bond: overlap of p orbital on C with p orbital on O

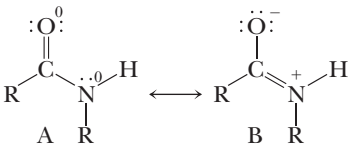
C—O single bond: The Lewis structure by itself would make it appear this bond is formed by the overlap of an sp^2 hybrid orbital on C with an sp^3 hybrid orbital on O. In the resonance hybrid, however, this oxygen would also have sp^2 hybridization.

9.57

MO theory pictures one net σ bond for each S—O linkage plus a contribution from π bonding. The π bonding in this molecule will be similar to that in O_3 discussed in the text. There will be two electrons in a π bonding MO and two electrons in a π nonbonding MO. This gives an overall bond order of 1 for the π bonding in the entire molecule and therefore a net π bond order of 0.5 for each S—O linkage. The total bond order for each S—O linkage is therefore 1.5 (1 from σ bonding, 0.5 from π bonding).

9.59 A C atom may form, at most, four hybrid orbitals (sp^3). The minimum number is two, for example, the sp hybrid orbitals used by carbon in CO. Carbon has only four valence orbitals, so it cannot form more than four hybrid orbitals.

9.61 (a) C, sp^2; N (predicted based on Lewis structure), sp^3
(b) The amide or peptide link has two resonance structures (shown here with formal charges on the O and N atoms). Structure B is less favorable, owing to the separation of charge.



A B

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(c) The fact that the amide link is planar indicates that structure B has some importance and that the N of the peptide linkage is sp^2 hybridized.

The principal sites of positive charge are the nitrogen in the amide linkage and the hydrogen of the —O—H group. The principal regions of negative charge are oxygen atoms and the nitrogen of the free $—NH_2$ group.

9.63 MO theory is better to use when explaining or understanding the effect of adding energy to molecules. A molecule can absorb energy and an electron can thus be promoted to a higher level. Using MO theory, one can see how this can occur. Additionally, MO theory is a better model to use to predict whether a molecule is paramagnetic.

9.65 Lowest energy = orbital C < orbital B < orbital A = highest energy

9.67 B surrounded by three electron pairs: electron-pair geometry = molecular geometry = trigonal planar; hybridization = sp^2; formal charge = 0

B surrounded by four electron pairs; electron-pair geometry = molecular geometry = tetrahedral; hybridization = sp^3; formal charge = −1

9.69 HF has a bond order of 1. HF_2^- has a bond order of 1 for the entire three-center-four-electron bond and thus a 0.5 bond order per H—F linkage. It should therefore be easier to break the bond in HF_2^-, leading to a smaller bond enthalpy for HF_2^- than for HF.

9.71 (a) empirical formula = Br_2O

The O should have sp^3 hybrid orbitals.

(b) 13 valence electrons; $(\sigma_s)^2(\sigma^*_s)^2(\pi_p)^4(\sigma_p)^2(\pi^*_p)^3$

HOMO = π^*_p

9.73 (a) Bonds broken: two N—H bonds, one N—H bond in each N in urea; two C—O bonds in malonic acid (at each end of the molecule). Bonds made: two N—C bond in barbituric acid; two O—H bonds, one in each molecule of H_2O (the other product of this reaction). Estimated enthalpy change calculated from average bond energies: 38 kJ evolved, exothermic.

(b) $H_2NCONH_2 + HO_2CCH_2CO_2H \rightarrow C_4H_4N_2O_3 + 2\ H_2O$

(c) 109.5° angles in bonds to C in the CH_2 group; all other angles will be close to 120°

(d) The C and N atoms in the ring are sp^2 hybridized except for the C atom of the CH_2 group where the C atom is sp^3 hybridized.

(e) C═O group, as the difference in electronegativity is greatest between C and O.

(f) yes, it is polar.

Chapter 10

Case Study

The Methane Mystery

1. Ratio $[CO_2]/[CH_4]$ = 390 ppm/0.1774 ppm = 2.2×10^3

2. Both C and P have tetrahedral geometry and sp^3 hybridization.

3. Oxidation number of P is +5

4. (a) mole fraction of CH_4 in air = 1.774×10^{-7} mol
(There is 1.774×10^{-7} mol of CH_4 in 1 mol of air.)

Vol of air = $(1.00\ km^3)(10^9\ m^3/km^3)(10^6\ cm^3/m^3)(1L/10^3\ cm) = 1.00 \times 10^{12}$ L

Moles gases in 1 km^3 of air: $n = PV/RT$ = (1.00 atm)$(1.00 \times 10^{12}$ L$)/[(0.08205$ L atm/mol K)(298 K)] = 4.09×10^{10} mol gases

Amt $CH_4 = (1.774 \times 10^{-7}$ mol CH_4/mol)$(4.09 \times 10^{10}$ mol) = 7.26×10^3 mol CH_4/km^3

Molecules CH_4 in 1 km^3 of air = $(7.26 \times 10^3$ mol $CH_4)(6.022 \times 10^{23}$ molecules/mol) = 4.37×10^{27} molecules CH_4

(b) $(7.26 \times 10^3$ mol $CH_3PO_3H^-)(95.0$ g/mol) = 6.90×10^5 g

Check Your Understanding

10.1 0.29 atm(760 mm Hg/1 atm) = 220 mm Hg
0.29 atm(1.01325 bar/1 atm) = 0.29 bar
0.29 bar$(10^5$ Pa/1 bar)(1 kPa/10^3 Pa) = 29 kPa

10.2 $V_2 = P_1V_1/P_2$ = (745 mm Hg)(65.0 L)/[0.70(745 mm Hg)] = 93 L

10.3 V_1 = 45 L and T_1 = 298 K; V_2 = ? and T_2 = 263 K
$V_2 = V_1(T_2/T_1)$ = (45 L)(263 K/298 K) = 40. L

10.4 $V_2 = V_1(P_1/P_2)(T_2/T_1)$ =
(22 L)(150 atm/0.993 atm)(295 K/304 K) = 3200 L

At 5.0 L per balloon, there is sufficient He to fill 640 balloons.

10.5 44.8 L of O_2(g) is required; 44.8 L of H_2O(g) and 22.4 L of CO_2(g) are produced.

10.6 $PV = nRT$

(750/760 atm)(V) = (1300 mol)(0.08206 L · atm/mol · K)(296 K)

$V = 3.2 \times 10^4$ L

10.7 According to Equation 10.5, density is inversely proportional to T (K).

d (at 55° C) = (1.18 g/L)(298 K/328 K) = 1.07 g/L

10.8 $PV = (m/M)RT$; $M = mRT/PV$

M = (0.105 g)(0.08206 L · atm/mol · K)(296.2 K)/[(561/760) atm (0.125 L)] = 27.8 g/mol

10.9 $2\ Na(s) + 2\ H_2O(\ell) \rightarrow 2\ NaOH(aq) + H_2(g)$

Amount H_2 = (15.0 g Na)(1 mol Na/22.99 g Na)(1 mol H_2/2 mol Na) = 0.326 mol

Volume of $H_2 = V = nRT/P$ = (0.326 mol)(0.08206 L atm/mol K)(298.2 K)/1.10 atm = 7.25 L

10.10 $P_{halothane}$ (5.00 L) = (0.0760 mol)(0.08206 L · atm/mol · K) (298.2 K)

$P_{halothane}$ = 0.372 atm (or 283 mm Hg)

P_{oxygen} (5.00 L) = (0.734 mol)(0.08206 L · atm/mol · K)(298.2 K)

P_{oxygen} = 3.59 atm (or 2730 mm Hg)

$P_{total} = P_{halothane} + P_{oxygen}$ = 283 mm Hg + 2730 mm Hg = 3010 mm Hg

10.11 For He: Use Equation 10.9, with $M = 4.00 \times 10^{-3}$ kg/mol, T = 298 K, and R = 8.314 J/mol · K to calculate the rms speed of 1360 m/s. A similar calculation for N_2, with $M = 28.01 \times 10^{-3}$ kg/mol, gives an rms speed of 515 m/s.

10.12 The molar mass of CH_4 is 16.0 g/mol.

$$\frac{\text{Rate for } CH_4}{\text{Rate for unknown}} = \frac{n \text{ molecules/1.50 min}}{n \text{ molecules/4.73 min}} = \sqrt{\frac{M_{unknown}}{16.0}}$$

$M_{unknown}$ = 159 g/mol

10.49 36 g/mol

10.51 (c) High pressure and low temperature (T near condensation point)

10.53 P from the van der Waals equation = 26.0 atm
P from the ideal gas law = 30.6 atm

10.55 (a) As an ideal gas, P = 162 atm. Using the van der Waals equation, P = 111.10 atm.
(b) $a(n/V^2)$

10.57 (a) Standard atmosphere: 1 atm; 760 mm Hg; 101.325 kPa; 1.013 bar
(b) N_2 partial pressure: 0.780 atm; 593 mm Hg; 79.1 kPa; 0.791 bar
(c) H_2 pressure: 131 atm; 9.98×10^4 mm Hg; 1.33×10^4 kPa; 133 bar
(d) Air: 0.333 atm; 253 mm Hg; 33.7 kPa; 0.337 bar

10.59 T = 290. K or 17 °C

10.61 $2\ C_4H_9SH(g) + 15\ O_2(g) \rightarrow 8\ CO_2(g) + 10\ H_2O(g) + 2\ SO_2(g)$
Total pressure = 37.3 mm Hg. Partial pressures: CO_2 = 14.9 mm Hg, H_2O = 18.6 mm Hg, and SO_2 = 3.73 mm Hg.

10.63 4 mol

10.65 V = 44.8 L O_2

10.67 Ni is the limiting reactant; 1.31 g $Ni(CO)_4$

10.69 (a, b) Sample 4 (He) has the largest number of molecules and sample 3 (H_2 at 27 °C and 760 mm Hg) has the fewest number of molecules.
(c) Sample 2 (Ar)

10.71 8.54 g $Fe(CO)_5$

10.73 S_2F_{10}

10.75 (a) 28.7 g/mol ≃ 29 g/mol
(b) X of O_2 = 0.17 and X of N_2 = 0.83

10.77 Molar mass = 86.4 g/mol. The gas is probably ClO_2F.

10.79 Calculate molar mass (44 g/mol). Gas is probably CO_2.

10.81 (d) is not correct. The rate of effusion is really inversely proportional to the square root of a gas's molar mass.

10.83 1.3×10^2 g/mol

10.85 n(He) = 0.0128 mol

10.87 Weight percent $KClO_3$ = 69.1%

10.89 (a) $NO_2 < O_2 < NO$
(b) $P(O_2)$ = 75 mm Hg
(c) $P(NO_2)$ = 150 mm Hg

10.91 $P(NH_3)$ = 69 mm Hg and $P(F_2)$ = 51 mm Hg
Pressure after reaction = 17 mm Hg

10.93 At 20 °C, there is 7.8×10^{-3} g H_2O/L. At 0 °C, there is 4.6×10^{-3} g H_2O/L.

10.95 The mixture contains 0.22 g CO_2 and 0.77 g CO.
$P(CO_2)$ = 0.22 atm; $P(O_2)$ = 0.12 atm; $P(CO)$ = 1.22 atm

10.97 The formula of the iron compound is $Fe(CO)_5$.

10.99 (a) $P(B_2H_6)$ = 0.0160 atm
(b) $P(H_2)$ = 0.0320 atm, so P_{total} = 0.0480 atm

10.101 Amount of Na_2CO_3 = 0.00424 mol
Amount of $NaHCO_3$ = 0.00951 mol
Amount of CO_2 produced = 0.0138 mol
Volume of CO_2 produced = 0.343 L

10.103 Decomposition of 1 mol of $Cu(NO_3)_2$ should give 2 mol NO_2 and ½ mol of O_2. Total actual amount = 4.72×10^{-3} mol of gas.
(a) Average molar mass = 41.3 g/mol
(b) Mole fractions: $X(NO_2)$ = 0.666 and $X(O_2)$ = 0.334
(c) Amount of each gas: 3.13×10^{-3} mol NO_2 and 1.57×10^{-3} mol O_2. The ratio of these amounts is 1.99 mol NO_2/mol O_2. This is different from the 4 mol NO_2/mol O_2 ratio expected from the reaction.
(d) If some NO_2 molecules combine to form N_2O_4, the apparent mole fraction of NO_2 would be smaller than expected (= 0.8). As this is the case, it is apparent that some N_2O_4 has been formed (as is observed in the experiment).

10.105 (a) M = 138 g/mol; the unknown compound is P_2F_4.
(b) $M = 1.4 \times 10^2$ g/mol; this is consistent with the result obtained in part (a).

10.107 (a) 10.0 g of O_2 represents more molecules than 10.0 g of CO_2. Therefore, O_2 has the greater partial pressure.
(b) The average speed of the O_2 molecules is greater than the average speed of the CO_2 molecules.
(c) The gases are at the same temperature and so have the same average kinetic energy.

10.109 (a) $P(C_2H_2) > P(CO)$
(b) There are more molecules in the C_2H_2 container than in the CO container.

10.111 (a) Not a gas. A gas would expand to an infinite volume.
(b) Not a gas. A density of 8.2 g/mL is typical of a solid.
(c) Insufficient information
(d) Gas

10.113 (a) There are more molecules of H_2 than atoms of He.
(b) The mass of He is greater than the mass of H_2.

10.115 The speed of gas molecules is related to the square root of the absolute temperature, so a doubling of the temperature will lead to an increase of about $(2)^{1/2}$ or 1.4.

Chapter 11

Case Study

A Pet Food Catastrophe

1. % N in melamine = 84/126 × 100 = 67%

% N in cyanuric acid = 42/129 × 100 = 33%

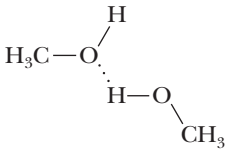
Both of these compounds have a greater percentage of nitrogen than the average protein.

2. 454 g sample (0.14 g melamine/1,000,000 g sample) = 6.4×10^{-5} g melamine = 0.064 mg melamine = 64 μg melamine

Check Your Understanding

11.1 Because F^- is the smaller ion, water molecules can approach more closely and interact more strongly. Thus, F^- should have the more negative enthalpy of hydration.

11.2



Hydrogen bonding in methanol entails the attraction of the hydrogen atom bearing a partial positive charge (δ^+) on one molecule to the oxygen atom bearing a partial negative charge (δ^-) on a second molecule. The strong attractive force of hydrogen bonding will cause the boiling point and the enthalpy of vaporization of methanol to be quite high.

11.3 Water is a polar solvent, while hexane and CCl_4 are nonpolar. London dispersion forces are the primary forces of attraction between all pairs of dissimilar solvents. For mixtures of water with the other solvents, dipole–induced dipole forces will also be important.

11.4 (a) O_2: induced dipole–induced dipole forces only.
(b) CH_3OH: strong hydrogen bonding (dipole–dipole forces) as well as induced dipole–induced dipole forces.
(c) Forces between water molecules: strong hydrogen bonding and induced dipole–induced dipole forces. Between N_2 and H_2O: dipole-induced dipole forces and induced dipole–induced dipole forces.

11.5 $(1.00 \times 10^3$ g)(1 mol/32.04 g)(35.2 kJ/mol) = 1.10×10^3 kJ

11.6 (a) At 40 °C, the vapor pressure of ethanol is about 120 mm Hg.
(b) The equilibrium vapor pressure of ethanol at 60 °C is about 320 mm Hg. At 60 °C and 600 mm Hg, ethanol is a liquid. If vapor is present, it will condense to a liquid.

Applying Chemical Principles: Chromatography

1. (a) The 1,5-pentanediol is most attracted to the mobile phase. The primary attractive force is hydrogen bonding. Dipole–dipole forces and dispersion forces are also present.
(b) The propyl ethyl ether is most attracted to the stationary phase by dispersion forces but there are also some dipole–induced dipole interactions.
(c) The molecules will elute in the following order (first to last): 1,5-pentanediol, 1-pentanol, and propyl ethyl ether.

Study Questions

11.1 (a) Dipole–dipole interactions (and hydrogen bonds)
(b) Induced dipole–induced dipole forces
(c) Dipole–dipole interactions (and hydrogen bonds)

11.3 (a) Induced dipole–induced dipole forces
(b) Induced dipole–induced dipole forces
(c) Dipole–dipole forces
(d) Dipole–dipole forces (and hydrogen bonding)

11.5 (a), (b), and (c). The boiling points of these liquids are: Ne, (−246 °C), CO (−192 °C), CH_4 (−162 °C), and CCl_4 (77 °C).

11.7 (c) HF; (d) acetic acid; (f) CH_3OH

11.9 (a) LiCl. The Li^+ ion is smaller than Cs^+ (Figure 7.12), which makes the ion–ion forces of attraction stronger in LiCl.
(b) $Mg(NO_3)_2$. The Mg^{2+} ion is smaller than the Na^+ ion (Figure 7.11), and the magnesium ion has a 2+ charge (as opposed to 1+ for sodium). Both of these effects lead to stronger ion–ion forces of attraction in magnesium nitrate.
(c) $NiCl_2$. The nickel(II) ion has a larger charge than Rb^+ and is considerably smaller. Both effects mean that there are stronger ion–ion forces of attraction in nickel(II) chloride.

11.11 q = +90.1 kJ

11.13 (a) Water vapor pressure is about 150 mm Hg at 60 °C. (Appendix G gives a value of 149.4 mm Hg at 60 °C.)
(b) 600 mm Hg at about 93 °C
(c) At 70 °C, ethanol has a vapor pressure of about 520 mm Hg, whereas that of water is about 225 mm Hg.

11.15 At 30 °C, the vapor pressure of ether is about 590 mm Hg. (This pressure requires 0.23 g of ether in the vapor phase at the given conditions, so there is sufficient ether in the flask.) At 0 °C, the vapor pressure is about 160 mm Hg, so some ether condenses when the temperature declines.

11.17 (a) O_2 (−183 °C) (bp of N_2 = −196 °C)
(b) SO_2 (−10 °C) (CO_2 sublimes at −78 °C)
(c) HF (+19.7 °C) (HI, −35.6 °C)
(d) GeH_4 (−90.0 °C) (SiH_4, −111.8 °C)

11.19 (a) CS_2, about 620 mm Hg; CH_3NO_2, about 80 mm Hg
(b) CS_2, induced dipole–induced dipole forces; CH_3NO_2, dipole–dipole forces
(c) CS_2, about 46 °C; CH_3NO_2, about 100 °C
(d) About 39 °C
(e) About 95 °C

11.21 (a) 80.1 °C
(b) At about 48 °C, the liquid has a vapor pressure of 250 mm Hg. The vapor pressure is 650 mm Hg at 75 °C.
(c) 33.5 kJ/mol (from slope of plot)

11.23 No, CO cannot be liquefied at room temperature because the critical temperature is lower than room temperature.

11.25 The layer of molecules on the surface of a liquid is harder to break through than the bulk liquid. The energy needed to break through this skin is the surface tension. An application of surface tension is that it is possible to float a paperclip on the surface of water, but if the paperclip breaks through the surface, it will sink. Surface tension results from intermolecular forces because molecules in the interior of a liquid interact through intermolecular forces with molecules all around them, but molecules on the surface have intermolecular forces only with molecules at or below the surface layer and thus feel a net inward force of attraction.

11.27 This phenomenon results from capillary action. The water is attracted to —OH groups in the paper. As a result of these adhesive forces, some water molecules begin to move up the paper. Other water molecules remain in contact with these water molecules by means of cohesive forces. A stream of water molecules thus moves up the paper.

11.29 (a) Induced dipole-induced dipole
(b) Induced dipole-induced dipole, dipole-dipole
(c) Induced dipole-induced dipole, dipole-dipole, hydrogen bonding.

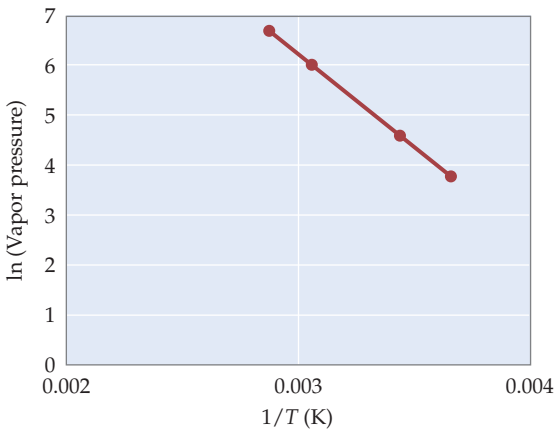
11.31 Li^+ ions are smaller than Cs^+ ions (78 pm and 165 pm, respectively; see Figure 7.11). Thus, there will be a stronger attractive force between Li^+ ion and water molecules than between Cs^+ ions and water molecules.

11.33 (a) 350 mm Hg
(b) Ethanol (lower vapor pressure at every temperature)
(c) 84 °C
(d) CS_2, 46 °C; C_2H_5OH, 78 °C; C_7H_{16}, 99 °C
(e) CS_2, gas; C_2H_5OH, gas; C_7H_{16}, liquid

11.35 Molar enthalpy of vaporization increases with increasing intermolecular forces: C_2H_6 (14.69 kJ/mol; induced dipole) < HCl (16.15 kJ/mol; dipole) < CH_3OH (35.21 kJ/mol, hydrogen bonds). (The molar enthalpies of vaporization here are given at the boiling point of the liquid.)

11.37 5.49×10^{19} atoms/m^3

11.39 (a) 70.3 °C
(b)



Using the equation for the straight line in the plot

$\ln P = -3885\ (1/T) + 17.949$

we calculate that T = 311.6 K (39.5 °C) when P = 250 mm Hg. When P = 650 mm Hg, T = 338.7 K (65.5 °C).
(c) Calculated $\Delta_{vap}H$ = 32.3 kJ/mol

11.41 (a) When the can is inverted in cold water, the water vapor pressure in the can, which was approximately 760 mm Hg, drops rapidly—say, to 9 mm Hg at 10 °C. This creates a partial vacuum in the can, and the can is crushed because of the difference in pressure inside the can and the pressure of the atmosphere pressing down on the outside of the can.
(b)

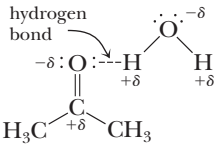
11.43 Acetone and water can interact by hydrogen bonding.



11.45 Ethylene glycol's viscosity will be greater than ethanol's, owing to the greater hydrogen-bonding capacity of glycol.

11.47 (a) Water has two OH bonds and two lone pairs, whereas the O atom of ethanol has only one OH bond (and two lone pairs). More extensive hydrogen bonding is likely for water.
(b) Water and ethanol interact extensively through hydrogen bonding, so the volume is expected to be slightly smaller than the sum of the two volumes.

11.49 Two pieces of evidence for $H_2O(\ell)$ having considerable intermolecular attractive forces:
(a) Based on the boiling points of the Group 6A hydrides (Figure 11.4), the boiling point of water should be approximately −80 °C. The actual boiling point of 100 °C reflects the significant hydrogen bonding that occurs.
(b) Liquid water has a specific heat capacity that is higher than almost any other liquid. This reflects the fact that a relatively larger amount of energy is necessary to overcome intermolecular forces and raise the temperature of the liquid.

11.51 (a) HI, hydrogen iodide
(b) The large iodine atom in HI leads to a significant polarizability for the molecule and thus to a large dispersion force.
(c) The dipole moment of HCl (1.07 D, Table 8.6) is larger than for HI (0.38 D).
(d) HI. See part (b).

11.53 A gas can be liquefied at or below its critical temperature. The critical temperature for CF_4 (−45.7 °C) is below room temperature (25 °C), so it cannot be liquefied at room temperature.

11.55 Hydrogen bonding is most likely at the O—H group at the "right" end of the molecule, and at the C═O and N—H groups in the amide group (—NH—CO—).

11.57 Boiling point, enthalpy of vaporization, volatility, surface tension

11.59 The more branching in the hydrocarbons, the lower the boiling point. This implies weaker induced dipole–induced dipole forces. Greater branching results in a more compact shape with less surface area available for contact and therefore smaller induced dipole–induced dipole forces.

11.61 $F_2 < Cl_2 < Br_2 < I_2$
$He < Ne < Ar < Kr < Xe$

Molar mass and boiling point correlate with these orders.

11.63 The boiling point of the water in the pressure cooker is 121 °C.

11.65 Using the equation of the line from Question 11.64, $P = 9.8$ atm.

11.67 (a) There will be water in the tube in equilibrium with its vapor, but almost all of the water will be present as liquid water.
(b) 760. mm Hg
(c) 10.4 cm^3
(d) 0.0233 g H_2O

Chapter 12

Case Studies

Lithium and "Green Cars"

1. 73,000,000 metric tons Li_2CO_3 (13.88 metric tons Li/73.89 metric tons Li_2CO_3) = 1.4×10^7 metric tons Li (= 14 million metric tons Li)

2. The unit cell for lithium metal is body-centered cubic. (There are atoms at each of the corners of a cube and one atom embedded in the middle of the cube.)

3. 351 pm (1 m/10^{12} pm)(100 cm/1 m) = 3.51×10^{-8} cm

V of unit cell = $(3.51 \times 10^{-8}\ cm)^3 = 4.32 \times 10^{-23}\ cm^3$

Mass of unit cell = 6.941 g Li/mol (1 mol/6.022×10^{23} atoms)(2 atoms/unit cell) = 2.305×10^{-23} g/unit cell

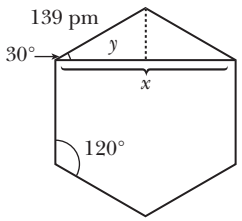
Density = mass/volume = 2.305×10^{-23} g/$4.32 \times 10^{-23}\ cm^3 = 0.533\ g/cm^3$

4. One method is to carry out the following gas-forming reaction:

$$Li_2CO_3(aq) + 2\ HCl(aq) \rightarrow 2\ LiCl(aq) + H_2O(\ell) + CO_2(g)$$

Nanotubes and Graphene—The Hottest New Network Solids

1. We want to know the distance x in the diagram of the hexagon. You know the interior angles in a hexagon are all 120°. To find x, we can find the distance y in the figure and then double it ($x = 2y$). The angle bounded by the side of the hexagon and y is 30°, and, from geometry, cos 30° = y/(hexagon side) so y = (cos 30°)(139 pm) = (0.866)(139 pm) = 120. pm. Finally, x = 241 pm.



2. 1.0 μm (1 m/10^6 μm)(10^{12} pm/1 m)(1 C_6-ring/241 pm) = 4.1×10^3 C_6-rings

3. The thickness would be approximately 150 pm. This corresponds to the diameter of a carbon atom, found by multiplying the radius of a carbon atom (given in Figure 7.7) by 2 and rounding off to two significant figures.

Check Your Understanding

12.1 (a) The strategy to solve this problem is given in Example 12.1.

Step 1. Mass of the unit cell
= (197.0 g/mol)(1 mol/6.022 × 10^{23} atom)
(4 atoms/unit cell)
= 1.309 × 10^{-21} g/unit cell

Step 2. Volume of unit cell
= (1.309 × 10^{-21} g/unit cell)(1 cm^3/19.32 g)
= 6.773 × 10^{-23} cm^3/unit cell

Step 3. Length of side of unit cell
= [6.773 × 10^{-23} cm^3/unit cell]$^{1/3}$
= 4.076 × 10^{-8} cm

Step 4. Calculate the radius from the edge dimension.

Diagonal distance = 4.076 × 10^{-8} cm ($2^{½}$) = 4 (r_{Au})

r_{Au} = 1.441 × 10^{-8} cm (= 144.1 pm)

(b) To verify a body-centered cubic structure, calculate the mass contained in the unit cell. If the structure is bcc, then the mass will be the mass of 2 Fe atoms. (Other possibilities: fcc − mass of 4 Fe; primitive cubic − mass of 1 Fe atom.) This calculation uses the four steps from the previous exercise in reverse order.

Step 1. Use radius of Fe to calculate cell dimensions. In a body-centered cube, atoms touch across the diagonal of the cube.

Diagonal distance = side dimension ($\sqrt{3}$) = 4 r_{Fe}

Side dimension of cube =
4 (1.26 × 10^{-8} cm)/($\sqrt{3}$) = 2.910 × 10^{-8} cm

Step 2. Calculate unit cell volume

Unit cell volume = (2.910 × 10^{-8} cm)^3 =
2.464 × 10^{-23} cm^3

Step 3. Combine unit cell volume and density to find the mass of the unit cell.

Mass of unit cell = 2.464 × 10^{-23} cm^3
(7.8740 g/cm^3) = 1.940 × 10^{-22} g

Step 4. Calculate the mass of 2 Fe atoms, and compare this to the answer from step 3.

Mass of 2 Fe atoms =
55.85 g/mol (1 mol/6.022 × 10^{23} atoms)(2 atoms)
= 1.85 × 10^{-22} g.

This is a fairly good match, and clearly much better than the two other possibilities, primitive and fcc.

12.2 M_2X. In a face-centered cubic unit cell, there are four anions and eight tetrahedral holes in which to place metal ions. All of the tetrahedral holes are inside the unit cell, so the ratio of atoms in the unit cell is 2:1.

12.3 We need to calculate the mass and volume of the unit cell from the information given. The density of KCl will then be mass/volume. Select units so the density is calculated as g/cm^3.

Step 1. Mass: The unit cell contains 4 K^+ ions and 4 Cl^- ions

Unit cell mass = (39.10 g/mol)(1 mol/6.022 × 10^{23} K^+ ions)(4 K^+ ions) + (35.45 g/mol)(1 mol/6.022 × 10^{23} Cl^- ions)(4 Cl^- ions) = 2.597 × 10^{-22} g + 2.355 × 10^{-22} g = 4.952 × 10^{-22} g

Step 2. Volume: Assuming K^+ and Cl^- ions touch along one edge of the cube, the side dimension = 2 r_{K^+} + 2 r_{Cl^-}. The volume of the cube is the cube of this value. (Convert the ionic radius from pm to cm.)

V = [2(1.33 × 10^{-8} cm) + 2(1.81 × 10^{-8} cm)]^3 = 2.477 × 10^{-22} cm^3

Step 3. Density = mass/volume =
4.952 ×10^{-22} g/2.477 × 10^{-22} cm^3) = 2.00 g/cm^3

Review & Check

Section 12-1

1. (b) body-centered cubic

2. (a) 0.858 g/cm^3

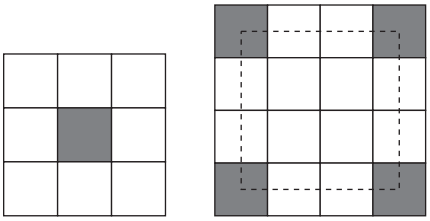
Study Questions

12.1 Two possible unit cells are illustrated here. The simplest formula is AB_8.



12.3 Ca^{2+} ions at eight corners = 1 net Ca^{2+} ion

O^{2-} ions in six faces = 3 net O^{2-} ions

Ti^{4+} ion in center of unit cell = 1 net Ti^{4+} ion

Formula = $CaTiO_3$

12.5 (a) There are eight O^{2-} ions at the corners and one in the center for a net of two O^{2-} ions per unit cell. There are four Cu ions in the interior in tetrahedral holes. The ratio of ions is Cu_2O.
(b) The oxidation number of copper must be +1.

12.7 Calcium atom radius = 197 pm

12.9 There are three ways the edge dimensions can be calculated:
(a) Calculate mass of unit cell (= 1.103×10^{-21} g/uc)

Calculate volume of unit cell from mass (= 3.53×10^{-22} cm^3/uc)

Calculate edge length from volume (= 707 pm)
(b) Assume I^- ions touch along the cell diagonal (◀ Check Your Understanding 12.1) and use I^- radius to find the edge length. Radius I^- = 220 pm

Edge = $4(220 \text{ pm})/2^{1/2}$ = 622 pm
(c) Assume the I^- and K^+ ions touch along the cell edge (page 449)

Edge = 2 × I^- radius + 2 × K^+ radius = 706 pm

Methods (a) and (c) agree. It is apparent that the sizes of the ions are such that the I^- ions cannot touch along the cell diagonal.

12.11 Increasing lattice energy: RbI < LiI < LiF < CaO

12.13 As the ion–ion distance decreases, the force of attraction between ions increases. This should make the lattice more stable, and more energy should be required to melt the compound.

12.15 $\Delta_f H° = -607$ kJ/mol

12.17 The 1000 2*s* orbitals will combine to form 1000 molecular orbitals. In the lowest energy state, 500 of these will be populated by pairs of electrons, and 500 will be empty.

12.19 In metals, thermal energy causes some electrons to occupy higher-energy orbitals in the band of molecular orbitals. For each electron promoted, two singly occupied levels result: a negative electron above the Fermi level and a positive hole below the Fermi level. Electrical conductivity results because in the presence of an electric field, these negative electrons will move toward the positive side of the field and the positive holes will move toward the negative side.

12.21 In carbon the band gap is too large for electrons to move up in energy from the valence band to the conduction band, whereas in silicon the band gap is small enough to permit this.

12.23 An intrinsic semiconductor (such as Si or Ge) is one that naturally can have electrons move across the band gap, whereas an extrinsic semiconductor (such as Ge with added As) requires the addition of dopants in order for it to conduct.

12.25 (a) Eight C atoms per unit cell. There are eight corners (= 1 net C atom), six faces (= 3 net C atoms), and four internal C atoms
(b) Face-centered cubic (fcc) with C atoms in the tetrahedral holes

12.27 Type of solid: particles, forces of attraction
(a) Metallic: metal atoms, metallic bonding
(b) Ionic: ions, ion–ion interactions
(c) Molecular: molecules, covalent bonds within the molecules and intermolecular forces between the molecules
(d) Network: extended network of covalently bonded atoms, covalent bonds
(e) Amorphous: covalently bonded networks with no long-range regularity, covalent bonds

12.29 Substance: type of solid, particles, forces, property
(a) Gallium arsenide: network, covalently bonded atoms, covalent bonds, semiconductor
(b) Polystyrene: amorphous, covalent bonds within the polymer molecules and dispersion forces between the polymer molecules, thermal insulator
(c) Silicon carbide: network, covalently bonded atoms, covalent bonds, very hard material
(d) Perovskite: ionic, Ca^{2+} and TiO_3^{2-} ions, ion–ion interactions, high melting point

12.31 *q* (for fusion) = −1.97 kJ; *q* (for melting) = +1.97 kJ

12.33 (a) The density of liquid CO_2 is less than that of solid CO_2.
(b) CO_2 is a gas at 5 atm and 0 °C.
(c) Critical temperature = 31 °C, so CO_2 cannot be liquefied at 45 °C.

12.35 *q* (to heat the liquid) = 9.4×10^2 kJ

q (to vaporize NH_3) = 1.6×10^4 kJ

q (to heat the vapor) = 8.8×10^2 kJ

$q_{total} = 1.8 \times 10^4$ kJ

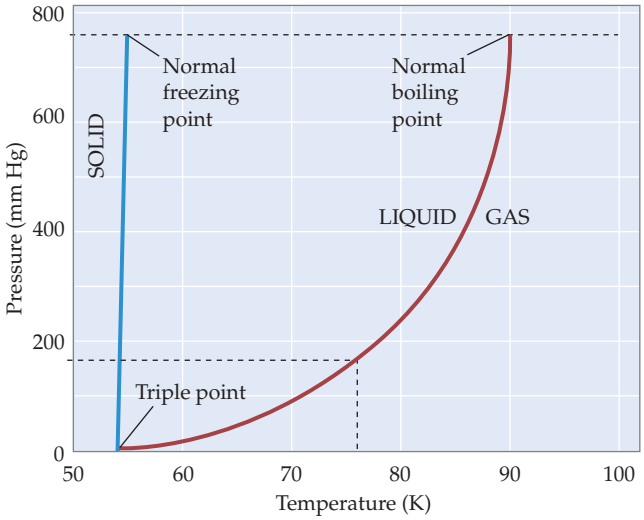
Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

12.37 O_2 phase diagram. (i) Note the slight positive slope of the solid–liquid equilibrium line. It indicates that the density of solid O_2 is greater than that of liquid O_2. (ii) Using the diagram here, the vapor pressure of O_2 at 77 K is between 150 and 200 mm Hg.



12.39 Radius of silver = 145 pm

12.41 1.356×10^{-8} cm (literature value is 1.357×10^{-8} cm)

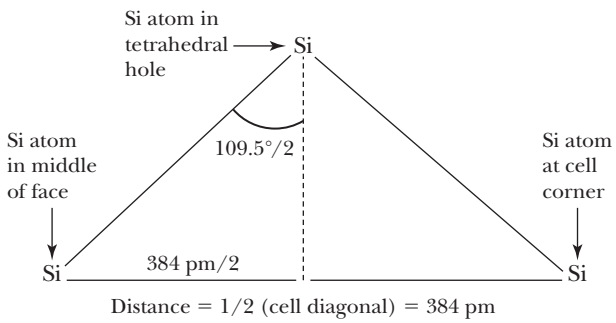
12.43 Mass of 1 CaF_2 unit calculated from crystal data = 1.2963×10^{-22} g. Divide molar mass of CaF_2 (78.077 g/mol) by mass of 1 CaF_2 to obtain Avogadro's number. Calculated value = 6.0230×10^{23} CaF_2/mol.

12.45 Diagram A leads to a surface coverage of 78.5%. Diagram B leads to 90.7% coverage.

12.47 (a) The lattice can be described as an fcc lattice of Si atoms.
(b) Si atoms are located in one half of the tetrahedral holes.
(c) There are eight Si atoms in the unit cell.
(d) Mass of unit cell = 3.731×10^{-22} g

Volume of unit cell = 1.602×10^{-22} cm^3

Density = 2.329 g/cm^3 (which is the same as the literature value)
(e) In the Si unit cell we cannot assume the atoms touch along the edge or along the face diagonal. Instead, we know that the Si atoms in the tetrahedral holes are bonded to the Si atoms at the corner.



Distance across cell face diagonal = 768 pm

Sin (109.5°/2) = 0.817 = (384 pm/2)/(Si-Si distance)

Distance from Si in tetrahedral hole to face or corner Si = 235 pm

Si radius = 118 pm

Figure 7.5 gives Si radius as 117 pm

12.49 (a) Mg^{2+} ions are in ⅛ of the eight possible tetrahedral holes, and Al^{3+} ions are in ½ of the four available octahedral holes.
(b) Fe^{2+} ions are in ⅛ of the eight possible tetrahedral holes, and Cr^{3+} ions are in ½ of the four available octahedral holes.

12.51 8.5×10^2 nm

12.53 Germanium has a smaller band gap, so it has a higher conductivity.

12.55 Because boron is electron deficient in comparison to carbon, this is a p-type semiconductor.

12.57 Lead sulfide has the same structure as sodium chloride, not the same structure as ZnS. There are four Pb^{2+} ions and four S^{2-} ions per unit cell, a 1:1 ratio that matches the compound formula.

12.59 4 formula units/unit cell; mass of unit cell = 7.904×10^{-22} g

Dimension of one side of unit cell = $2r(K^+) + 2r(Br^-) = 6.58 \times 10^{-8}$ cm; so volume of the unit cell = $side^3 = 2.85 \times 10^{-22}$ cm^3

Density = 7.902×10^{-22} g/2.85×10^{-22} cm^3 = 2.77 g/cm^3

12.61 (a) $BBr_3(g) + PBr_3(g) + 3\ H_2(g) \rightarrow BP(s) + 6\ HBr(g)$
(b) If B atoms are in an fcc lattice, then the P atoms must be in ½ of the tetrahedral holes. (In this way it resembles Si in Question 12.47.)
(c) Unit cell volume = 1.092×10^{-22} cm^3
Unit cell mass = 2.775×10^{-22} g
Density = 2.54 g/cm^3
(d) The solution to this problem is identical to Question 12.47. In the BP lattice, the cell face diagonal is 676 pm. Therefore, the calculated BP distance is 207 pm.

12.63 Assuming the spheres are packed in an identical way, the water levels are the same. A face-centered cubic lattice, for example, uses 74% of the available space, regardless of the sphere size.

12.65 Step 1. There are four atoms within a ccp unit cell. Calculate the volume of these four atoms (V of a sphere = $(4/3)\pi r^3$).

Step 2. Calculate the total volume of the unit cell ($V_{cell} = side^3$).

Step 3. Percent occupancy = $(V_{atoms}/V_{cell})100\%$

12.67 (a) Two triple points. One with diamond, graphite and liquid C; the second with liquid C, graphite, and carbon vapor.
(b) no

(c) diamond
(d) Graphite is the stable form of carbon at room temperature and 1 atmosphere of pressure.

Chapter 13

Case Study

Henry's Law and Exploding Lakes

1. $PV = nRT$

4.0 atm(0.025 L) = n(0.08206 L · atm/mol · K)(298 K); $n = 4.1 \times 10^{-3}$ mol

2. $P_1V_1 = P_2V_2$

4.0 atm(0.025 L) = 3.7×10^{-4} atm (V_2); V_2 = 270 L

The gas expanded by a factor of 11,000 (= 270 L/0.025 L).

3. Solubility of $CO_2 = k_H P_g$ = 0.034 mol/kg · bar (3.7×10^{-4} bar) = 1.3×10^{-5} mol/kg

4. Before opening: Solubility of CO_2 before opening = $k_H P_g$ = 0.034 mol/kg · bar (4.0 bar) = 0.14 mol/kg

Assume the density of the solution is 1.0 g/cm^3, therefore 1.0 L corresponds to 1.0 kg. The amount of CO_2 dissolved is 0.14 mol.

After opening: Solubility of $CO_2 = 1.3 \times 10^{-5}$ mol/kg as calculated in part 3 above. The amount of CO_2 in 1.0 kg is 1.3×10^{-5} mol.

Mass of CO_2 released = (0.14 mol CO_2 − 1.3×10^{-5} mol CO_2)(44.01 g CO_2/1 mol CO_2) = 6.0 g CO_2

Check Your Understanding

13.1 (a) 10.0 g sucrose = 0.0292 mol; 250. g H_2O = 13.9 mol

$X_{sucrose}$ = (0.0292 mol)/(0.0292 mol + 13.9 mol) = 0.00210

$c_{sucrose}$ = (0.0292 mol sucrose)/(0.250 kg solvent) = 0.117 m

Weight % sucrose = (10.0 g sucrose/260 g soln)(100%) = 3.85%

(b) 1.08×10^4 ppm = 1.08×10^4 mg Na^+ per 1000 g soln = (1.08×10^4 mg Na^+/1000 g soln)(1050 g soln/1 L) = 1.13×10^4 mg Na^+/L = 11.3 g Na^+/L

(11.3 g Na^+/L)(58.44 g NaCl/23.0 g Na^+) = 28.8 g NaCl/L

13.2 $\Delta_{soln}H° = \Delta_f H°[NaOH(aq)] - \Delta_f H°[NaOH(s)]$
= −469.2 kJ/mol − (−425.9 kJ/mol)
= −43.3 kJ/mol

13.3 Solubility of $CO_2 = k_H P_g$ = 0.034 mol/kg · bar × 0.33 bar = 1.1×10^{-2} mol/kg

13.4 The solution contains sucrose [(10.0 g)(1 mol/342.3 g) = 0.0292 mol] in water [(225 g)(1 mol/18.02 g) = 12.5 mol].

X_{water} = (12.5 mol H_2O)/(12.5 mol + 0.0292 mol) = 0.998

$P_{water} = X_{water}P°_{water}$ = 0.998(149.4 mm Hg) = 149 mm Hg

13.5 $c_{glycol} = \Delta T_{bp}/K_{bp}$ = 1.0 °C/(0.512 °C/m) = 2.0 m = 2.0 mol/kg

$mass_{glycol}$ = (2.0 mol/kg)(0.125 kg)(62.07 g/mol) = 15 g

13.6 c_{glycol} = (525 g)(1 mol/62.07 g)/(3.00 kg) = 2.82 m

$\Delta T_{fp} = K_{fp} \times m$ = (−1.86 °C/m)(2.82 m) = −5.24 °C

You will be protected only to about −5 °C and not to −25 °C.

13.7 c (mol/L) = (0.033 g bradykinin)(1 mol bradykinin/1060 g bradykinin)/0.0500 L = 6.2×10^{-4} M

$\Pi = cRT$ = (6.2×10^{-4} mol/L)(0.082057 L · atm/mol · K)(293 K) = 0.015 atm

13.8 ΔT_{fp} = 5.265 °C − 5.50 °C = −0.24 °C

$\Delta T_{fp} = K_{fp} \times m_{solute}$

m_{solute} = −0.24 °C/−5.12 °C/m = 0.046 mol/kg

m_{solute} = (0.046 mol solute/kg benzene)(0.02346 kg benzene) = 0.0011 mol solute

M = 0.448 g/0.0011 mol = 4.2×10^2 g/mol

M(compound)/M(empirical formula) = 4.2×10^2 g/mol/104.1 g/mol = 4.0

Molecular formula = $(C_2H_5)_8Al_4F_4$

13.9 c (mol/L) = Π/RT = [(1.86 mm Hg)(1 atm/760 mm Hg)]/[(0.08206 L · atm/mol · K)(298 K)] = 1.00×10^{-4} M

(1.00×10^{-4} mol/L)(0.100 L) = 1.00×10^{-5} mol

Molar mass = 1.40 g/1.00×10^{-5} mol = 1.4×10^5 g/mol

(Assuming the polymer is composed of CH_2 units, the polymer is about 10,000 units long.)

13.10 c_{NaCl} = (25.0 g NaCl)(1 mol/58.44 g)/(0.525 kg) = 0.815 m

$\Delta T_{fp} = K_{fp} \times m \times i$ = (−1.86 °C/m)(0.815 m)(1.85) = −2.80 °C

Review & Check

Section 13-1

1. (b) 0.063
(b) 3.7

2. (b) 0.88 mol/kg

Section 13-2

1. (c) −23.55 kJ/mol

Section 13-3

1. (b) 0.097 mol

Section 13-4

1. (b) Na_2SO_4 < sugar < KBr < $C_2H_4(OH)_2$

2. (d) naphthalene, $C_{10}H_8$

3. (c) 1.0 g propylene glycol, $C_3H_6(OH)_2$

4. (c) 122 g/mol

Section 13-5

1. (b) 40 million atoms.

Applying Chemical Principles: Distillation

1. X(hexane) = 0.59

3. Mass percent (hexane) = 18%

Study Questions

13.1 (a) Concentration (m) = 0.0434 m
(b) Mole fraction of acid = 0.000781
(c) Weight percent of acid = 0.509%

13.3 NaI: 0.15 m; 2.2%; $X = 2.7 \times 10^{-3}$
CH_3CH_2OH: 1.1 m; 5.0%; X = 0.020
$C_{12}H_{22}O_{11}$: 0.15 m; 4.9%; $X = 2.7 \times 10^{-3}$

13.5 2.65 g Na_2CO_3; $X(Na_2CO_3) = 3.59 \times 10^{-3}$

13.7 220 g glycerol; 5.7 m

13.9 16.2 m; 37.1%

13.11 Molality = 2.6×10^{-5} m (assuming that 1 kg of seawater is equivalent to 1 kg of solvent)

13.13 (b) and (c)

13.15 $\Delta_{soln}H°$ for LiCl = −36.9 kJ/mol. This is an exothermic enthalpy of solution, as compared with the very slightly endothermic value for NaCl.

13.17 Above about 40 °C the solubility increases with temperature; therefore, add more NaCl and raise the temperature.

13.19 2×10^{-3} g O_2

13.21 1100 mm Hg or 1.5 bar

13.23 (a) $S = 2.0 \times 10^{-3}$ mol/kg
(b) Raising the pressure to 1.7 atm will result in an increased concentration of dissolved O_2; lowering the pressure to 1.0 atm will lead to a lower concentration of dissolved O_2.

13.25 35.0 mm Hg

13.27 $X(H_2O)$ = 0.869; 16.7 mol glycol; 1040 g glycol

13.29 Calculated boiling point = 84.2 °C

13.31 ΔT_{bp} = 0.808 °C; solution boiling point = 62.51 °C

13.33 Molality = 8.60 m; 28.4%

13.35 Molality = 0.195 m; ΔT_{fp} = fp = −0.362 °C

13.37 (a) ΔT_{fp} = −0.348 °C; fp = −0.348 °C
(b) ΔT_{bp} = +0.0959 °C; bp = 100.0959 °C
(c) Π = 4.58 atm
The osmotic pressure is large and can be measured with a small experimental error.

13.39 Molar mass = 6.0×10^3 g/mol

13.41 Molar mass = 360 g/mol; $C_{20}H_{16}Fe_2$

13.43 Molar mass = 150 g/mol

13.45 Molar mass = 170 g/mol

13.47 Freezing point = −24.6 °C

13.49 0.08 m $CaCl_2$ < 0.1 m NaCl < 0.04 m Na_2SO_4 < 0.1 sugar

13.51 (a) $BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$
(b) Initially, the $BaSO_4$ particles form a colloidal suspension.
(c) Over time, the particles of $BaSO_4$(s) grow and precipitate.

13.53 Molar mass = 110 g/mol

13.55 (a) Increase in vapor pressure of water
0.20 m Na_2SO_4 < 0.50 m sugar < 0.20 m KBr < 0.35 m ethylene glycol
(b) Increase in boiling point
0.35 m ethylene glycol < 0.20 m KBr < 0.50 m sugar < 0.20 m Na_2SO_4

13.57 (a) 0.456 mol DMG and 11.4 mol ethanol; X(DMG) = 0.0385
(b) 0.869 m
(c) VP ethanol over the solution at 78.4 °C = 730.7 mm Hg
(d) bp = 79.5 °C

13.59 For ammonia: 23 m; $X(NH_3)$ = 0.29; 28%

13.61 0.592 g Na_2SO_4

13.63 (a) 0.20 m KBr; (b) 0.10 m Na_2CO_3

13.65 Freezing point = −11 °C

13.67 4.0×10^2 g/mol

13.69 4.7×10^{-4} mol/kg

13.71 (a) Molar mass = 4.9×10^4 g/mol
(b) $\Delta T_{fp} = -3.8 \times 10^{-4}$ °C

13.73 $\Delta_{soln}H°$ [Li_2SO_4] = −28.0 kJ/mol
$\Delta_{soln}H°$ [LiCl] = −36.9 kJ/mol
$\Delta_{soln}H°$ [K_2SO_4] = +23.7 kJ/mol
$\Delta_{soln}H°$ [KCl] = +17.2 kJ/mol
Both lithium compounds have exothermic enthalpies of solution, whereas both potassium compounds have endothermic values. Consistent with this is the fact that lithium salts (LiCl) are often more water-soluble than potassium salts (KCl) (see Figure 13.11).

13.75 X(benzene in solution) = 0.67 and X(toluene in solution) = 0.33

$$P_{total} = P_{toluene} + P_{benzene} = 7.3 \text{ mm Hg} + 50. \text{ mm Hg} = 57 \text{ mm Hg}$$

$$X(\text{toluene in vapor}) = \frac{7.3 \text{ mm Hg}}{57 \text{ mm Hg}} = 0.13$$

$$X(\text{benzene in vapor}) = \frac{50. \text{ mm Hg}}{57 \text{ mm Hg}} = 0.87$$

13.77 i = 1.7. That is, there is 1.7 mol of ions in solution per mole of compound.

13.79 (a) Calculate the number of moles of ions in 10^6 g H_2O: 550. mol Cl^-; 470. mol Na^+; 53.1 mol Mg^{2+}; 9.42 mol SO_4^{2-}; 10.3 mol Ca^{2+}; 9.72 mol K^+; 0.84 mol Br^-. Total moles of ions = 1.103×10^3 per 10^6 g water. This gives ΔT_{fp} of −2.05 °C.

(b) Π = 27.0 atm. This means that a minimum pressure of 27 atm would have to be used in a reverse osmosis device.

13.81 (a) i = 2.06

(b) There are approximately two particles in solution, so $H^+ + HSO_4^-$ best represents H_2SO_4 in aqueous solution.

13.83 Mass of N_2O = 0.53 g; concentration = 1.1×10^3 ppm

13.85 The best method would be to shine a laser through the liquid and look for the Tyndall effect. Some other properties of colloids that could be utilized are that the dispersed material in a colloid will either not crystallize or crystallize only with difficulty and will either not diffuse across a membrane or do so much more slowly than a true solute.

13.87 The calculated molality at the freezing point of benzene is 0.47 m, whereas it is 0.99 m at the boiling point. A higher molality at the higher temperature indicates more molecules are dissolved. Therefore, assuming benzoic acid forms dimers like acetic acid (page 413), dimer formation is more prevalent at the lower temperature. In this process two molecules become one entity, lowering the number of separate species in solution and lowering the molality.

13.89 Molar mass in benzene = 1.20×10^2 g/mol; molar mass in water = 62.4 g/mol. The actual molar mass of acetic acid is 60.1 g/mol. In benzene, the molecules of acetic acid form "dimers." That is, two molecules form a single unit through hydrogen bonding (see page 413).

13.91 The empirical formula, calculated from the percent composition data, is $C_7H_6N_2$. The calculated molar mass of the compound is 118 g/mol, which agrees with the molar mass calculated from the vapor pressure data.

13.93 The strength of the interactions is related to the size of the ion. Thus, Be^{2+} is most strongly hydrated, and Ca^{2+} is least strongly hydrated.

13.95 Colligative properties depend on the number of ions or molecules in solution. Each mole of $CaCl_2$ provides 1.5 times as many ions as each mole of NaCl.

13.97 Benzene is a nonpolar solvent. Thus, ionic substances such as $NaNO_3$ and NH_4Cl will certainly not dissolve. However, naphthalene is also nonpolar and resembles benzene in its structure; it should dissolve very well. (A chemical handbook gives a solubility of 33 g naphthalene per 100 g benzene.) Diethyl ether is weakly polar but is miscible to some extent with benzene.

Water is a polar solvent. The ionic compounds, $NaNO_3$ and NH_4Cl, are both soluble in water ($NaNO_3$ solubility (at 25 °C) = 91 g per 100 g water; NH_4Cl solubility (at 25 °C) = 40 g per 100 g water. The slightly polar compound diethyl ether is soluble to a small extent in water (about 6 g per 100 g water at 25 °C). Nonpolar naphthalene is not soluble in water (solubility at 25 °C = 0.003 g per 100 g water).

13.99 The C—C and C—H bonds in hydrocarbons are nonpolar or weakly polar and tend to make such dispersions hydrophobic (water-hating). The C—O and O—H bonds in starch present opportunities for hydrogen bonding with water. Hence, starch is expected to be more hydrophilic.

13.101 [NaCl] = 1.0 M and [KNO_3] = 0.88 M. The KNO_3 solution has a higher solvent concentration, so solvent will flow from the KNO_3 solution to the NaCl solution.

13.103 (a) $X(C_2H_5OH)$ = 0.051; $X(H_2O)$ = 0.949

(b) $P(C_2H_5OH)$ over mixture = 38 mm Hg; $P°(H_2O)$ calculated by linear interpolation using the vapor pressures at 78 °C and 79 °C = 334.2 mm Hg; $P(H_2O)$ over mixture = 317 mm Hg

(c) $X(C_2H_5OH)$ = 0.11; $X(H_2O)$ = 0.89

(d) The mole fraction of ethanol increased from 0.051 to 0.11, a factor of 2.2 times.

Weight percent of C_2H_5OH = 24%

13.105 The molality of the 5.00% NaCl solution is 0.901 m. Assuming no dissociation, this leads to ΔT_{fp}(calculated) = −1.68 °C and i = 1.82. The molality of the 5.00% Na_2SO_4 solution is 0.371 m, ΔT_{fp}(calculated) = −0.689 °C, and i = 1.97. These values are consistent with the trends seen in Table 13.4. As the concentration of the ionic solute increases, the value of i continues to decrease for both solutes, and rate of decrease is falling for both solutes. In the case of NaCl, this value is leveling off quite a bit. In the case of Na_2SO_4, it is continuing to decrease by significant amounts. Interestingly, the value of i for Na_2SO_4 has now fallen below 2 and is getting closer to that for NaCl.

13.107 This does not lend credence to this story. The reported lowest temperature for a NaCl solution corresponds to a temperature of 2.372 °F. The temperature of 0 °F is still below this.

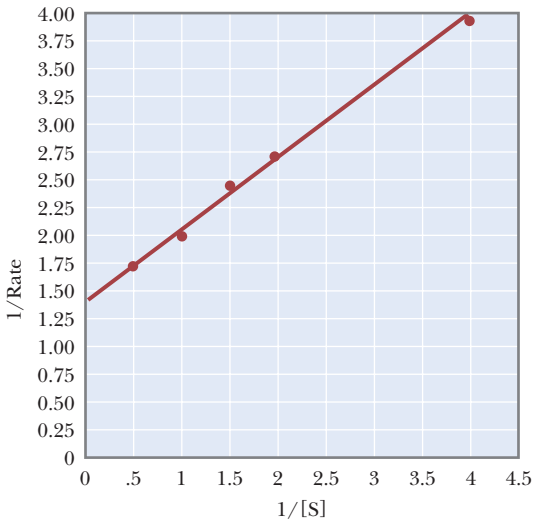
Chapter 14

Case Study

Enzymes—Nature's Catalysts

1. To decompose an equivalent amount of H_2O_2 catalytically would take 1.0×10^{-7} years; this is equivalent to 3.2 seconds.

2.



[S]	1/[S]	Rate	1/Rate
2.50	0.400	0.588	1.70
1.00	1.00	0.500	2.00
0.714	1.40	0.417	2.40
0.526	1.90	0.370	2.70
0.250	4.00	0.256	3.91

From the graph, we obtain a value of 1/Rate = 1.47 when 1/[S] = 0. From this, R_{max} = 0.68 mmol/min.

Check Your Understanding

14.1 For the first 2 hours:

$-\Delta[\text{sucrose}]/\Delta t = -[(0.033 - 0.050)\text{ mol/L}]/(2.0\text{ h}) = 0.0085\text{ mol/L} \cdot \text{h}$

For the last 2 hours:

$-\Delta[\text{sucrose}]/\Delta t = -[(0.010 - 0.015)\text{ mol/L}]/(2.0\text{ h}) = 0.003\text{ mol/L} \cdot \text{h}$

Instantaneous rate at 4 hours = 0.0045 mol/L · h. (Calculated from the slope of a line tangent to the curve at the defined concentration.)

14.2 $-\frac{1}{2}(\Delta[\text{NOCl}]/\Delta t) = \frac{1}{2}(\Delta[\text{NO}]/\Delta t) = \Delta[\text{Cl}_2]/\Delta t$

14.3 Compare experiments 1 and 2: Doubling $[O_2]$ causes the rate to double, so the rate is first order in $[O_2]$. Compare experiments 2 and 4: Doubling [NO] causes the rate to increase by a factor of 4, so the rate is second order in [NO]. Thus, the rate law is

$\text{Rate} = -(\Delta[\text{NO}]/\Delta t) = k[\text{NO}]^2[\text{O}_2]$

Using the data in experiment 1 to determine k:

$0.028\text{ mol/L} \cdot \text{s} = k[0.020\text{ mol/L}]^2[0.010\text{ mol/L}]$

$k = 7.0 \times 10^3\text{ L}^2/\text{mol}^2 \cdot \text{s}$

14.4 $\text{Rate} = k[\text{Pt(NH}_3)_2\text{Cl}_2] = (0.27\text{ h}^{-1})(0.020\text{ mol/L}) = 0.0054\text{ mol/L} \cdot \text{h}$

14.5 $\ln([\text{sucrose}]/[\text{sucrose}]_o) = -kt$

$\ln([\text{sucrose}]/[0.010]) = -(0.21\text{ h}^{-1})(5.0\text{ h})$

$[\text{sucrose}] = 0.0035\text{ mol/L}$

14.6 (a) The fraction remaining is $[CH_3N_2CH_3]/[CH_3N_2CH_3]_o$.

$\ln([CH_3N_2CH_3]/[CH_3N_2CH_3]_o) = -(3.6 \times 10^{-4}\text{ s}^{-1})(150\text{ s})$

$[CH_3N_2CH_3]/[CH_3N_2CH_3]_o = 0.95$

(b) After the reaction is 99% complete $[CH_3N_2CH_3]/[CH_3N_2CH_3]_o = 0.010$

$\ln(0.010) = -(3.6 \times 10^{-4}\text{ s}^{-1})(t)$

$t = 1.3 \times 10^4\text{ s}$ (210 min)

14.7 $1/[\text{HI}] - 1/[\text{HI}]_o = kt$

$1/[\text{HI}] - 1/[0.010\text{ M}] = (30.\text{ L/mol} \cdot \text{min})(12\text{ min})$

$[\text{HI}] = 0.0022\text{ M}$

14.8 (0.060 M/0.24 M) = 0.25; thus ¼ of the original material remains and two half-lives have transpired. $t_{1/2}$ = 141 min.

$k = \ln 2/t_{1/2} = (\ln 2)/141\text{ min} = 4.92 \times 10^{-3}\text{ min}^{-1}$

Initial rate = $k[\text{H}_2\text{O}_2]_0$ = $4.92 \times 10^{-3}\text{ min}^{-1}\ (0.24\text{ mol/L}) = 1.2 \times 10^{-3}\text{ mol/L} \cdot \text{min}$

14.9 (a) For ^{241}Am, $t_{1/2} = 0.693/k = 0.693/(0.0016\text{ y}^{-1}) = 430$ y

For ^{125}I, $t_{1/2} = 0.693/(0.011\text{ d}^{-1}) = 63$ d

(b) ^{125}I decays much faster.

(c) $\ln[(n)/(1.6 \times 10^{15}\text{ atoms})] = -(0.011\text{ d}^{-1})(2.0\text{ d})$

$n/1.6 \times 10^{15}\text{ atoms} = 0.978$;

$n = 1.57 \times 10^{15}$ atoms

Since the answer should have two significant figures, we should round this off to 1.6×10^{15} atoms. The approximately 2% that has decayed is not discernable within the limits of accuracy of the data presented.

14.10 An Arrhenius plot was constructed by plotting ln k on the y-axis and $1/T$ on the x-axis. Using Microsoft Excel, the equation of the best-fit line is $y = -22336x + 27.304$.

$E_a = -R \cdot (\text{slope}) = -(0.0083145\text{ kJ/mol} \cdot \text{K})(-22336\text{ K}) = 1.9 \times 10^2\text{ kJ/mol}$

14.11 $\ln(k_2/k_1) = (-E_a/R)(1/T_2 - 1/T_1)$

$\ln[(1.00 \times 10^4)/(4.5 \times 10^3)] = -(E_a/8.3145 \times 10^{-3}\text{ kJ/mol} \cdot \text{K})(1/283\text{ K} - 1/274\text{ K})$

$E_a = 57\text{ kJ/mol}$

14.12 All three steps are bimolecular.

For step 3: $\text{Rate} = k[\text{N}_2\text{O}][\text{H}_2]$.

There are two intermediates, N_2O_2(g) and N_2O(g).

When the three equations are added, N_2O_2 (a product in the first step and a reactant in the second step) and N_2O (a product in the second step and a reactant in the third step) cancel, leaving the net equation:

$2\text{ NO(g)} + 2\text{ H}_2\text{(g)} \rightarrow \text{N}_2\text{(g)} + 2\text{ H}_2\text{O(g)}$.

14.13 (a) $2\ NH_3(aq) + OCl^-(aq) \rightarrow N_2H_4(aq) + Cl^-(aq) + H_2O(\ell)$
(b) The second step is the rate-determining step.
(c) Rate = $k[NH_2Cl][NH_3]$
(d) NH_2Cl, $N_2H_5^+$, and OH^- are intermediates.

14.14 Overall reaction: $2\ NO_2Cl(g) \rightarrow 2\ NO_2(g) + Cl_2(g)$
Rate = $k'[NO_2Cl]^2/[NO_2]$ (where $k' = k_1k_2/k_{-1}$)
Increasing $[NO_2]$ causes the reaction rate to decrease.

Review & Check

Section 14-1

1. (b) The rate of disappearance of NO(g) is twice the rate of disappearance of $O_2(g)$.

2. (c) 0.6×10^{-5} mol/L · min

Section 14-2

1. (b) decreasing the concentration of one of the reactants.

Section 14-3

1. (b) 1.24×10^{-5} mol/L · s

Section 14-4

1. (b) between 6 and 7

2. (d) A graph of $\ln[SO_2Cl_2]$ vs. time gives a straight line.

3. (b) second order

Section 14-5

1. (c) ln k vs. 1/T

2. (b) A higher proportion of reactant molecules exceeds the activation energy.

Section 14-6

1. (b) This reaction might occur in a single elementary step.

2. (c) Rate = $k[A]^2[B]$

Applying Chemical Principles: Kinetics and Mechanisms: A 70-Year-Old Mystery Solved

1. (a) 207 kJ/mol photons
(b) 792 nm

3. The probability of three particles colliding simultaneously with the correct geometry for a successful reaction is low.

Study Questions

14.1 (a) $-\frac{1}{2}\frac{\Delta[O_3]}{\Delta t} = \frac{1}{3}\frac{\Delta[O_2]}{\Delta t}$

(b) $-\frac{1}{2}\frac{\Delta[HOF]}{\Delta t} = \frac{1}{2}\frac{\Delta[HF]}{\Delta t} = \frac{\Delta[O_2]}{\Delta t}$

14.3 $\frac{1}{3}\frac{\Delta[O_2]}{\Delta t} = -\frac{1}{2}\frac{\Delta[O_3]}{\Delta t}$ or $\frac{\Delta[O_3]}{\Delta t} = -\frac{2}{3}\frac{\Delta[O_2]}{\Delta t}$

so $\Delta[O_3]/\Delta t = -1.0 \times 10^{-3}$ mol/L · s.

14.5 (a) The graph of [B] (product concentration) versus time shows [B] increasing from zero. The line is curved, indicating the rate changes with time; thus the rate depends on concentration. Rates for the four 10–s intervals are as follows: 0–10 s, 0.0326 mol/L · s; from 10–20 s, 0.0246 mol/L · s; 20–30 s, 0.0178 mol/L · s; 30–40 s, 0.0140 mol/L · s.

(b) $-\frac{\Delta[A]}{\Delta t} = \frac{1}{2}\frac{\Delta[B]}{\Delta t}$ throughout the reaction

In the interval 10–20 s, $\frac{\Delta[A]}{\Delta t} = -0.0123\ \frac{mol}{L \cdot s}$

(c) Instantaneous rate when [B] = 0.750 mol/L = $\frac{\Delta[B]}{\Delta t} = 0.0163\ \frac{mol}{L \cdot s}$

14.7 The reaction is second order in A, first order in B, and third order overall.

14.9 (a) Rate = $k[NO_2][O_3]$
(b) If $[NO_2]$ is tripled, the rate triples.
(c) If $[O_3]$ is halved, the rate is halved.

14.11 (a) The reaction is second order in [NO] and first order in $[O_2]$.

(b) Rate = $\frac{-\Delta[NO]}{\Delta t} = k[NO]^2[O_2]$

(c) $k = 25\ L^2/mol^2 \cdot s$
(d) Rate = 2.8×10^{-5} mol/L · s
(e) When $-\Delta[NO]/\Delta t = 1.0 \times 10^{-4}$ mol/L · s, $\Delta[O_2]/\Delta t = 5.0 \times 10^{-5}$ mol/L · s and $\Delta[NO_2]/\Delta t = 1.0 \times 10^{-4}$ mol/L · s.

14.13 (a) Rate = $-\Delta[NO]/\Delta t = k[NO]^2[O_2]$
(b) $50.\ L^2/mol^2 \cdot h$
(c) Rate = 8.4×10^{-9} mol/L · h

14.15 $k = 3.73 \times 10^{-3}\ min^{-1}$

14.17 5.0×10^2 min

14.19 (a) 153 min
(b) 1790 min

14.21 140 s

14.23 6.3 s

14.25 (a) $t_{1/2} = 1.0 \times 10^4$ s (b) 34,000 s

14.27 1.0×10^3 min

14.29 Fraction of ^{64}Cu remaining = 0.030

14.31 The straight line obtained in a graph of $\ln[N_2O]$ versus time indicates a first-order reaction.
k = (−slope) = $0.0128\ min^{-1}$
The rate when $[N_2O] = 0.035$ mol/L is 4.5×10^{-4} mol/L · min.

14.33 The graph of $1/[NO_2]$ versus time gives a straight line, indicating the reaction is second order with respect to $[NO_2]$ (see Table 14.1 on page 524). The slope of the line is k, so $k = 1.1$ L/mol · s.

14.35 $-\Delta[C_2F_4]/\Delta t = k[C_2F_4]^2 = (0.04\ L/mol \cdot s)[C_2F_4]^2$

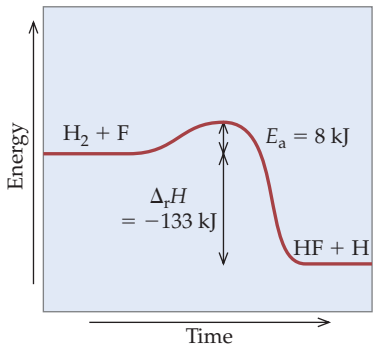
Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

14.37 Activation energy = 102 kJ/mol

14.39 $k = 0.3\ s^{-1}$

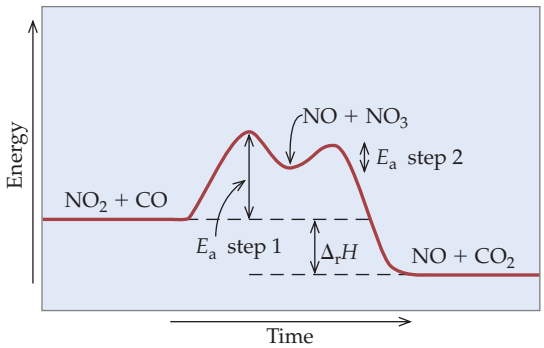
14.41



14.43 (a) Rate = $k[NO_3][NO]$
(b) Rate = $k[Cl][H_2]$
(c) Rate = $k[(CH_3)_3CBr]$

14.45 (a) The second step; (b) Rate = $k[O_3][O]$

14.47 (a) NO_2 is a reactant in the first step and a product in the second step. CO is a reactant in the second step. NO_3 is an intermediate, and CO_2 is a product. NO is a product.
(b) Reaction coordinate diagram



14.49 Doubling the concentration of A will increase the rate by a factor of 4 because the concentration of A appears in the rate law as $[A]^2$. Halving the concentration of B will halve the rate The net result is that the rate of the reaction will double.

14.51 After measuring pH as a function of time, one could then calculate pOH and then $[OH^-]$. Finally, a plot of $1/[OH^-]$ versus time would give a straight line with a slope equal to k.

14.53 72 s represents two half-lives, so $t_{1/2} = 36$ s.

14.55 (a) A plot of $1/[C_2F_4]$ versus time indicates the reaction is second order with respect to $[C_2F_4]$. The rate law is Rate = $k[C_2F_4]^2$.
(b) The rate constant (= slope of the line) is about 0.045 L/mol · s. (The graph does not allow a very accurate calculation.)
(c) Using $k = 0.045$ L/mol · s, the concentration after 600 s is 0.03 M (to one significant figure).
(d) Time = 2000 s [using k from part (b)].

14.57 (a) A plot of $1/[NH_4NCO]$ versus time is linear, so the reaction is second order with respect to NH_4NCO.
(b) Slope = k = 0.0109 L/mol · min.
(c) $t_{1/2}$ = 200. min
(d) $[NH_4NCO]$ = 0.0997 mol/L

14.59 Mechanism 2

14.61 $k = 0.0176\ h^{-1}$ and $t_{1/2} = 39.3$ h

14.63 (a) After 125 min, 0.250 g remains. After 145, 0.144 g remains.
(b) Time = 43.9 min
(c) Fraction remaining = 0.016

14.65 Plotting 1/concentration versus the time gives a reasonably good linear correlation. The reaction is second order.

14.67 The rate equation for the slow step is Rate = $k[O_3][O]$. The equilibrium constant, K, for step 1 is $K = [O_2][O]/[O_3]$. Solving this for [O], we have $[O] = K[O_3]/[O_2]$. Substituting the expression for [O] into the rate equation we find

Rate = $k[O_3]\{K[O_3]/[O_2]\} = kK[O_3]^2/[O_2]$

14.69 The slope of the ln k versus $1/T$ plot is −6370. From slope = $-E_a/R$, we derive E_a = 53.0 kJ/mol.

14.71 Step 2 is the rate-determining step, and N_2O_2 is an intermediate.

Rate = $-\frac{1}{2}\,\Delta[NO]/\Delta t = k[NO]^2[O_2]$

14.73 (a) k = 3.41 L/mol · min
(b) The rate constant (k') for the rewritten equation is ½ the value of the rate constant, k, for the original equation. The rate equation for the original equation is $-\Delta[NO_2]/\Delta t = k[NO_2]$. For the rewritten equation the rate equation is $-(\frac{1}{2})\Delta[NO_2]/\Delta t = k'[NO_2]$ or $-\Delta[NO_2]/\Delta t = 2k'[NO_2]$. Therefore, $k = 2k'$ or $k' = (\frac{1}{2})k$.

14.75 Estimated time at 90 °C = 4.76 min

14.77 After 30 min (one half-life), P_{HOF} = 50.0 mm Hg and P_{total} = 125.0 mm Hg. After 45 min, P_{HOF} = 35.4 mm Hg and P_{total} = 132 mm Hg.

14.79 (a) Reaction is first order in NO_2NH_2 and −1 for H_3O^+. In a buffered solution, $[H_3O]^+$ is constant, so the reaction has an apparent order of 1.
(b, c) Mechanism 3

In step 1, $K = k_4/k_4' = [NO_2NH^-][H_3O^+]/[NO_2NH_2]$

Rearrange this and substitute into the rate law for the slow step.

Rate = $k_5[NO_2NH^-] = k_5K[NO_2NH_2]/[H_3O^+]$

This is the same as the experimental rate law, where the overall rate constant $k = k_5K$.
(d) Addition of OH^- ions will shift the equilibrium in step 1 (by reacting with H_3O^+) to produce a larger concentration of NO_2NH^-, the reactant in the rate-determining step, thus the reaction rate will increase.

14.81 (a) Average rate for $t = 0$ to $t = 15$ is about 4.7×10^{-5} M/s. For $t = 100$ s to 125 s, the average rate is about 1.6×10^{-5} M/s. The rate slows because the rate of the reaction is dependent on the concentration of reactant and this concentration is declining with time.
(b) Instantaneous rate at 50 s is about 2.7×10^{-5} M/s.
(c) A plot of ln (concentration) versus time is a straight line with an equation of $y = -0.010x - 5.30$. This indicates the reaction is a first-order reaction; Rate = k[phenolphthalein]. The slope, which is equal to $-k$, is -0.010, so $k = 0.010\ s^{-1}$.
(d) From the data the half-life is 69.3 s, and the same value comes from the relation $t_{1/2} = \ln 2/k$.

14.83 A plot of 1/Rate versus 1/[S] gives the equation

$1/\text{Rate} = 94\ (1/[S]) + 7.6 \times 10^4$

so $\text{Rate}_{max} = 1/(7.6 \times 10^4) = 1.3 \times 10^{-5}$ M min^{-1}.

14.85 (a) The reaction is first order in [ClO^-] (experiments 1 and 3), first order in [I^-] (experiments 2 and 3), and -1 order in [OH^-] (experiments 3 and 4). Therefore, Rate = $k[ClO^-][I^-]/[OH^-]$
(b) Step 2 is the rate determining step. For this step, rate = $k[I^-][HOCl]$. From the first step, $K_{eq} = [HOCl][OH^-]/[ClO^-]$, so $[HOCl] = K_{eq}[ClO^-]/[OH^-]$; substituting for [HOCl] in the rate equation for the second step gives the observed rate law.

14.87 The finely divided rhodium metal will have a significantly greater surface area than the small block of metal. This leads to a large increase in the number of reaction sites and vastly increases the reaction rate.

14.89 (a) False. The reaction may occur in a single step but this does not have to be true.
(b) True
(c) False. Raising the temperature increases the value of k.
(d) False. Temperature has no effect on the value of E_a.
(e) False. If the concentrations of both reactants are doubled, the rate will increase by a factor of 4.
(f) True

14.91 (a) True
(b) True
(c) False. As a reaction proceeds, the reactant concentration decreases and the rate decreases.
(d) False. It is possible to have a one-step mechanism for a third-order reaction if the slow, rate-determining step is termolecular.

14.93 (a) Decrease (d) No change
(b) Increase (e) No change
(c) No change (f) No change

14.95 (a) There are three mechanistic steps.
(b) The overall reaction is exothermic.

Chapter 15

Case Study

Applying Equilibrium Concepts—The Haber-Bosch Ammonia Process

1. (a) Oxidize part of the NH_3 to HNO_3, then react NH_3 and HNO_3 (an acid–base reaction) to form NH_4NO_3.

$4\ NH_3 + 7\ O_2 \rightarrow 4\ NO_2 + 6\ H_2O$

$2\ NO_2 + H_2O \rightarrow HNO_3 + HNO_2$

$HNO_3 + NH_3 \rightarrow NH_4NO_3$

(b) $\Delta_r H° = (1\text{ mol } (NH_2)_2CO/\text{mol-rxn})[\Delta_f H°\{(NH_2)_2CO\}] + (1\text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)] - (2\text{ mol } NH_3/\text{mol-rxn})[\Delta_f H°(NH_3)] - (1\text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)]$

$\Delta_r H° = (1\text{ mol } (NH_2)_2CO/\text{mol-rxn})(-333.1\text{ kJ/mol}) + (1\text{ mol } H_2O/\text{mol-rxn})(-241.8\text{ kJ/mol}) - (2\text{ mol } NH_3/\text{mol-rxn})(-45.90\text{ kJ/mol}) - (1\text{ mol } CO_2/\text{mol-rxn})(-393.5\text{ kJ/mol})$

$\Delta_r H° = -89.6$ kJ/mol-rxn.

The reaction as written is exothermic, so the equilibrium will be more favorable for product formation at a low temperature. The reaction converts three moles of gaseous reactants to one mole of gaseous products; thus, high pressure will be more favorable to product formation.

2. (a) For $CH_4(g) + H_2O(g) \rightarrow CO(g) + 3\ H_2(g)$

$\Delta_r H° = (1\text{ mol CO/mol-rxn})[\Delta_f H°(CO)] - (1\text{ mol } CH_4/\text{mol-rxn})[\Delta_f H°(CH_4)] - (1\text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)]$

$\Delta_r H° = (1\text{ mol CO/mol-rxn})(-110.5\text{ kJ/mol}) - (1\text{ mol } CH_4/\text{mol-rxn})(-74.87\text{ kJ/mol}) - (1\text{ mol } H_2O/\text{mol-rxn})(-241.8\text{ kJ/mol}) =$ 206.2 kJ/mol-rxn (endothermic)

For $CO(g) + H_2O(g) \rightarrow CO_2(g) + H_2(g)$

$\Delta_r H° = (1\text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)] - (1\text{ mol CO/mol-rxn})[\Delta_f H°(CO)] - (1\text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)]$

$\Delta_r H° = (1\text{ mol } CO_2/\text{mol-rxn})(-393.5\text{ kJ/mol}) - (1\text{ mol CO/mol-rxn})(-110.5\text{ kJ/mol}) - (1\text{ mol } H_2O/\text{mol-rxn})(-241.8\text{ kJ/mol}) =$ -41.2 kJ/mol-rxn (exothermic)

(b) (15 billion kg = 1.5×10^{13} g)

Add the two equations:
$CH_4(g) + 2\ H_2O(g) \rightarrow CO_2(g) + 4\ H_2(g)$

CH_4 required = $(1.5 \times 10^{13}\text{ g } NH_3)(1\text{ mol } NH_3/17.03\text{ g } NH_3)(3\text{ mol } H_2/2\text{ mol } NH_3)(1\text{ mol } CH_4/4\text{ mol } H_2)(16.04\text{ g } CH_4/1\text{ mol } CH_4) = 5.3 \times 10^{12}$ g CH_4

CO_2 formed = $(1.5 \times 10^{13}\text{ g } NH_3)(1\text{ mol } NH_3/17.03\text{ g } NH_3)(3\text{ mol } H_2/2\text{ mol } NH_3)(1\text{ mol } CO_2/4\text{ mol } H_2)(44.01\text{ g } CO_2/1\text{ mol } CO_2) = 1.5 \times 10^{13}$ g CO_2

Check Your Understanding

15.1 (a) $K = [CO]^2/[CO_2]$
(b) $K = [Cu^{2+}][NH_3]^4/[Cu(NH_3)_4{}^{2+}]$
(c) $K = [H_3O^+][CH_3CO_2^-]/[CH_3CO_2H]$

15.2 (a) $Q = 0.00218/0.00097 = 2.2$. The system is not at equilibrium; $Q < K$. To reach equilibrium, [isobutane] will increase and [butane] will decrease.
(b) $Q = 0.00260/0.00075 = 3.5$. The system is not at equilibrium; $Q > K$. To reach equilibrium, [butane] will increase and [isobutane] will decrease.

15.3 (a)

Equation	$C_6H_{10}I_2$	$\rightleftharpoons$	C_6H_{10}	+	I_2
Initial (M)	0.050		0		0
Change (M)	−0.035		+0.035		+0.035
Equilibrium (M)	0.015		0.035		0.035

(b) $K = (0.035)\ (0.035)/(0.015) = 0.082$

15.4

Equation	H_2	+	I_2	$\rightleftharpoons$	2 HI
Initial (M)	6.00×10^{-3}		6.00×10^{-3}		0
Change (M)	$-x$		$-x$		$+2x$
Equilibrium (M)	$0.00600 - x$		$0.00600 - x$		$+2x$

$$K_c = 33 = \frac{(2x)^2}{(0.00600 - x)^2}$$

$x = 0.0045$ M, so $[H_2] = [I_2] = 0.0015$ M and $[HI] = 0.0090$ M.

15.5

Equation	$PCl_5(g)$	$\rightleftharpoons$	$PCl_3(g)$	+	$Cl_{2(g)}$
Initial (M)	0.1000		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$0.1000 - x$		x		x

$K_c = [PCl_3][Cl_2]/[PCl_5]$

$33.3 = x^2/0.1000 - x$

We cannot use the simplifying assumption in this case (K is > 1 and $100 \cdot K > 0.1000$), so we must solve using the quadratic formula.

$x^2 + 33.3x - 3.33 = 0$

Using the quadratic formula, $x = 0.0997$ (the other root, $x = -33.4$, is not possible because it leads to negative concentrations).

$[PCl_3] = [Cl_2] = 0.0997$ M

$[PCl_5] = 0.1000$ M $- 0.0997$ M $= 0.0003$ M

15.6 (a) $K' = K^2 = (2.5 \times 10^{-29})^2 = 6.3 \times 10^{-58}$
(b) $K'' = 1/K^2 = 1/(6.3 \times 10^{-58}) = 1.6 \times 10^{57}$

15.7

Equation	Butane	$\rightleftharpoons$	Isobutane
Initial (M)	0.020		0.050
After adding more isobutane (M)	0.020		0.050 + 0.020
Change (M)	$+x$		$-x$
Equilibrium (M)	$0.020 + x$		$0.070 - x$

$K = (0.070 - x)/(0.020 + x)$

Solving for x gives $x = 0.0057$ M. Therefore, [isobutane] $= 0.070 - 0.0057 = 0.064$ M and [butane] $= 0.020 + 0.0057 = 0.026$ M.

Review & Check

Section 15-1

1. (c) The forward and reverse reactions occur at an equal rate.

Section 15-2

1. (b) $K = [SO_2]^2[O_2]/[SO_3]^2$

2. (b) No, it is not at equilibrium, and the reaction proceeds further to the right.

Section 15-3

1. (b) 6.1×10^{-4}

Section 15-4

1. (b) 0.011 M

Section 15-5

1. (c) $K_p = 2.7 \times 10^{33}$

Section 15-6

1. (b) shift right

2. (a) shift left

Applying Chemical Principles: Trivalent Carbon

1. (a) Concentration (molality) $= -0.542\ °C/-5.12\ °C/m =$ 0.106 mol dimer/kg benzene

Amount dimer = (0.106 mol dimer/kg benzene) (0.0100 kg benzene) $= 1.06 \times 10^{-3}$ mol dimer

Molar mass of dimer $= 0.503$ g/1.06×10^{-3} mol = 475 g/mol

(b) Each molecule of the dimer that decomposes produces two monomer particles, increasing the total number of moles of particles in solution. When the mass of the dimer is divided by the moles of particles, the calculated molar mass is too low.

3. [Monomer] $= 0.0045$ M, [dimer] $= 0.0503$ M

5. (b) Triphenylmethyl radical

Study Questions

15.1 (a) $K_c = \dfrac{[H_2O]^2[O_2]}{[H_2O_2]^2}$

(b) $K_c = \dfrac{[CO_2]}{[CO][O_2]^{1/2}}$

(c) $K_c = \dfrac{[CO]^2}{[CO_2]}$

(d) $K_c = \dfrac{[CO_2]}{[CO]}$

15.3 $Q = (2.0 \times 10^{-8})^2/(0.020) = 2.0 \times 10^{-14}$
$Q < K_c$, so the reaction proceeds to the right.

15.5 $Q = 1.0 \times 10^3$, so $Q > K_c$ and the reaction is not at equilibrium. It proceeds to the left to convert products to reactants.

15.7 $K_c = 1.2$

15.9 (a) $K_c = 0.025$
(b) $K_c = 0.025$
(c) The amount of solid does not affect the equilibrium.

15.11 (a) $[COCl_2] = 0.00308$ M; $[CO] = 0.0071$ M
(b) $K_c = 140$

15.13 [isobutane] = 0.024 M; [butane] = 0.010 M

15.15 $[I_2] = 6.14 \times 10^{-3}$ M; $[I] = 4.79 \times 10^{-3}$ M

15.17 $[COBr_2] = 0.0026$ M; $[CO] = [Br_2] = 0.0224$ M
89.6% of the $COBr_2$ has decomposed.

15.19 (b)

15.21 (e) $K_2 = 1/(K_1)^2$

15.23 $K_c = 13.7$

15.25 (a) $K_c = K_p/(RT)^{\Delta n} = 0.16/[(0.08205)(298)] = 6.5 \times 10^{-3}$
(b) $\Delta n = 0$, therefore $K_c = K_p = 1.05$

15.27 (a) Equilibrium shifts to the right
(b) Equilibrium shifts to the left
(c) Equilibrium shifts to the right
(d) Equilibrium shifts to the left

15.29 Equilibrium concentrations are the same under both circumstances: [butane] = 1.1 M and [isobutane] = 2.9 M.

15.31 $K = 3.9 \times 10^{-4}$

15.33 For decomposition of $COCl_2$, $K_c = 1/(K_c$ for $COCl_2$ formation$) = 1/(6.5 \times 10^{11}) = 1.5 \times 10^{-12}$

15.35 $K_c = 3.9$

15.37 Q is less than K_c, so the system shifts to form more isobutane.

At equilibrium, [butane] = 0.86 M and [isobutane] = 2.14 M.

15.39 The second equation has been reversed and multiplied by 2.
(c) $K_2 = 1/K_1^2$

15.41 (a) No change
(b) Shifts left
(c) No change
(d) Shifts right
(e) Shifts right

15.43 (a) The equilibrium will shift to the left on adding more Cl_2.
(b) K_c is calculated (from the quantities of reactants and products at equilibrium) to be 0.00470. After Cl_2 is added, the concentrations are: $[PCl_5] = 0.00199$ M, $[PCl_3] = 0.00231$ M, and $[Cl_2] = 0.00403$ M.

15.45 $K_p = 0.215$

15.47 (a) Fraction dissociated = 0.15
(b) Fraction dissociated = 0.189. If the pressure decreases, the equilibrium shifts to the right, increasing the fraction of N_2O_4 dissociated.

15.49 $[NH_3] = 0.67$ M; $[N_2] = 0.57$ M; $[H_2] = 1.7$ M; $P_{total} = 180$ atm

15.51 (a) $[NH_3] = [H_2S] = 0.013$ M
(b) $[NH_3] = 0.027$ M and $[H_2S] = 0.0067$ M

15.53 $P(NO_2) = 0.066$ atm and $P(N_2O_4) = 0.066$ atm; P(total) = 0.16 atm

15.55 (a) $K_p = K_c = 56$. Because 2 mol of reactant gases gives 2 mol of product gases, Δn does not change and $K_p = K_c$ (◀ page 560).
(b) Total pressure before reaction is 0.52 atm. After reaction the total pressure is the same because the amount of gas present has not changed.
(c) After reaction, at equilibrium, $P(H_2) = P(I_2) = 0.052$ atm and $P(HI) = 0.42$ atm.

15.57 $P(CO) = 0.0010$ atm

15.59 3.9×10^{17} O atoms

15.61 Glycerin concentration should be 1.7 M

15.63 (a) $K_p = 0.20$
(b) When initial $[N_2O_4] = 1.00$ atm, the equilibrium pressures are $[N_2O_4] = 0.80$ atm and $[NO_2] = 0.40$ atm. When initial $[N_2O_4] = 0.10$ atm, the equilibrium pressures are $[N_2O_4] = 0.050$ atm and $[NO_2] = 0.10$ atm. The percent dissociation is now 50.%. This is in accord with Le Chatelier's principle: If the initial pressure of the reactant is smaller, the equilibrium shifts to the right, increasing the fraction of the reactant dissociated. [This might be clearer if you imagine beginning with the equilibrium system in the case when the initial pressure of N_2O_4 was 1.00 atm and then increasing the volume tenfold (obtaining the same equilibrium system as starting with 0.10 atm N_2O_4). Le Chatelier's principle predicts a shift in the direction that has a greater number of gas molecules. See also Question 15.45.]

15.65 (a) The flask containing $(H_3N)B(CH_3)_3$ will have the largest partial pressure of $B(CH_3)_3$.
(b) $P[B(CH_3)_3] = P(NH_3) = 0.23$ and $P[(H_3N)B(CH_3)_3] = 0.012$ atm

$P_{total} = 0.48$ atm

Percent dissociation = 95%

15.67 (a) As more KSCN is added, Le Chatelier's principle predicts more of the red complex ion $[Fe(H_2O)_5(SCN)]^+$ will form.
(b) Adding Ag^+ ions leads to a precipitate of AgSCN, thus removing SCN^- ions from solution. The equilibrium shifts left, dropping the concentration of the red complex ion.

15.69 (a) False. The magnitude of K is always dependent on temperature.
(b) True
(c) False. The equilibrium constant for a reaction is the reciprocal of the value of K for its reverse.
(d) True
(e) False. $\Delta n = 1$, so $K_p = K_c(RT)$

15.71 (a) Product-favored, $K >> 1$
(b) Reactant-favored, $K << 1$
(c) Product-favored, $K >> 1$

15.73 Begin with an equilibrium system containing $^{14}N_2$, H_2, and $^{14}NH_3$. Introduce some $^{15}N_2$ and allow the system to equilibrate. The presence of $^{15}NH_3$ indicates that the forward reaction has occurred. In addition, the presence of $^{15}N^{14}N$ indicates that the reverse reaction has occurred. Further evidence of the reverse reaction occurring could be obtained by carrying out another trial in which $^{15}NH_3$ is added to the initial equilibrium mixture. The presence of $^{15}N^{14}N$ or $^{15}N_2$ indicates that the reverse reaction is occurring. (A similar set of experiments could be run using ^2H instead of ^{15}N.)

15.75 $K_p = 3.2 \times 10^{-7}$

Chapter 16

Case Study

Would You Like Some Belladonna Juice in Your Drink?

1. (100. mg $C_{17}H_{23}NO_3$)(1 g/1000 mg)(1 mol $C_{17}H_{23}NO_3$/289.4 g $C_{17}H_{23}NO_3$) = 3.46×10^{-4} mol $C_{17}H_{23}NO_3$

2. The proton will attach to the N.

3. The pK_a of protonated atropine (4.35) is less than that of the ammonium (pK_a = 9.26), methylammonium (pK_a = 10.70), and anilinium (pK_a = 4.60) ions.

Check Your Understanding

16.1 $[H_3O^+] = 4.0 \times 10^{-3}$ M; $[OH^-] = K_w/[H_3O^+] = 2.5 \times 10^{-12}$ M

16.2 (a) pH = 7
(b) pH < 7 (NH_4^+ is an acid)
(c) pH < 7 $[Al(H_2O)_6]^{3+}$ is an acid
(d) pH > 7 (HPO_4^{2-} is a stronger base than it is an acid)

16.3 (a) NH_4^+ is a stronger acid than HCO_3^-. CO_3^{2-}, the conjugate base of HCO_3^-, is a stronger base than NH_3, the conjugate base of NH_4^+.
(b) Reactant-favored; the reactants are the weaker acid and base.
(c) Reactant-favored; the reactants are the weaker acid and base, so reaction lies to the left.

16.4 From the pH, we can calculate $[H_3O^+] = 1.9 \times 10^{-3}$ M. Also, [butanoate$^-$] = $[H_3O^+] = 1.9 \times 10^{-3}$ M. Use these values along with [butanoic acid] to calculate K_a.

$K_a = [1.9 \times 10^{-3}]\,[1.9 \times 10^{-3}]/(0.055 - 1.9 \times 10^{-3}) = 6.8 \times 10^{-5}$

16.5 $K_a = 1.8 \times 10^{-5} = [x][x]/(0.10 - x)$

$x = [H_3O^+] = [CH_3CO_2^-] = 1.3 \times 10^{-3}$ M; $[CH_3CO_2H] = 0.099$ M; pH = 2.87

16.6 $HF(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + F^-(aq)$

$K_a = 7.2 \times 10^{-4} = [x][x]/(0.00150 - x)$

The x in the denominator cannot be dropped. This equation must be solved with the quadratic formula or by successive approximations. Because this problem follows the section dealing with the method of successive approximations, that method will be used here.

$7.2 \times 10^{-4} = x^2/(0.00150)$; $x = 1.0 \times 10^{-3}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 1.0 \times 10^{-3})$; $x = 6.0 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 6.0 \times 10^{-4})$; $x = 8.0 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 8.0 \times 10^{-4})$; $x = 7.1 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.1 \times 10^{-4})$; $x = 7.5 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.5 \times 10^{-4})$; $x = 7.3 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.3 \times 10^{-4})$; $x = 7.4 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.4 \times 10^{-4})$; $x = 7.4 \times 10^{-4}$

The result has converged to two significant figures.

$[H_3O^+] = [F^-] = 7.4 \times 10^{-4}$ M

[HF] = 0.00150 M − 7.4 10^{-4} M = 7.6×10^{-4} M

pH = 3.13

16.7 $OCl^-(aq) + H_2O(\ell) \rightleftharpoons HOCl(aq) + OH^-(aq)$

$K_b = 2.9 \times 10^{-7} = [x][x]/(0.015 - x)$

$x = [OH^-] = [HOCl] = 6.6 \times 10^{-5}$ M

pOH = 4.18; pH = 9.82

16.8 Equivalent amounts of acid and base react to form water, $CH_3CO_2^-$ and Na^+. Acetate ion hydrolyzes to a small extent, giving CH_3CO_2H and OH^-. We need to determine $[CH_3CO_2^-]$ and then solve a weak base equilibrium problem to determine $[OH^-]$.

Amount $CH_3CO_2^-$ = moles base = 0.12 mol/L × 0.015 L = 1.8×10^{-3} mol

Total volume = 0.030 L, so $[CH_3CO_2^-] = (1.8 \times 10^{-3}$ mol)/0.030 L = 0.060 M

$CH_3CO_2^-(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2H(aq) + OH^-(aq)$

$K_b = 5.6 \times 10^{-10} = [x][x]/(0.060 - x)$

$x = [OH^-] = [CH_3CO_2H] = 5.8 \times 10^{-6}$ M

pOH = 5.24; pH = 8.76

16.9 $H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HC_2O_4^-(aq)$

$K_{a1} = 5.9 \times 10^{-2} = [x][x]/(0.10 - x)$

The x in the denominator cannot be dropped. This equation must be solved with the quadratic formula or by successive approximations.

$x = [H_3O^+] = [HC_2O_4^-] = 5.3 \times 10^{-2}$ M

pH = 1.28

$K_{a2} = [H_3O^+][C_2O_4^{2-}]/[HC_2O_4^-]$; because $[H_3O^+] = [HC_2O_4^-]$

$[C_2O_4^{2-}] = K_{a2} = 6.4 \times 10^{-5}$ M

Review & Check

Section 16-1

1. (c) amphiprotic
2. (b) base
3. (b) acid = HNO_3 and conjugate base = NO_3^-
   (a) base = NH_3 and conjugate acid = NH_4^+
4. (c) HF/F^- and $CH_3CO_2H/CH_3CO_2^-$

Section 16-2

1. (b) 11.08
2. (a) 4.8×10^{-5} M
3. (d) 1.4×10^{-4} M

Section 16-3

1. (a) HF
2. (c) HCN
3. (a) $C_6H_5CO_2H$
4. (b) 9.25
5. (c) 10.15

Section 16-4

1. (b) decrease
2. (a) increase

Section 16-5

1. (b) product-favored
2. (b) right

Section 16-6

1. (a) acidic
2. (a) acidic
3. (b) basic

Section 16-7

1. (b) 6.3×10^{-6} M
2. (a) 2.3×10^{-5}
3. (b) pH = 8.37, $[Na^+] = 0.10$ M, $[CHO_2^-] = 0.10$ M, $[OH^-] = 2.4 \times 10^{-6}$ M
4. (c) greater than 7

Section 16-8

2. (b) $[Fe(H_2O)_6]^{3+}$
3. (a) HOCl

Section 16-10

1. (b) BCl_3
2. (c) Brønsted base and (d) Lewis base

Applying Chemical Principles: The Leveling Effect, Nonaqueous Solvents, and Superacids

1. $HClO_4$ ($K = 5 \times 10^{-6}$) > H_2SO_4 ($K = 2 \times 10^{-7}$) > HCl ($K = 2 \times 10^{-9}$)
3. $NH_2^-(aq) + H_2O(\ell) \rightleftharpoons NH_3(aq) + OH^-(aq)$
   The reaction is product-favored at equilibrium.
5. (a) $2\ NH_3 \rightleftharpoons NH_4^+ + NH_2^-$
   (b) The strongest acid is NH_4^+; the strongest base is NH_2^-.
   (c) HCl is a stronger acid than NH_4^+, so HCl will be completely ionized. The solution will be a strong conductor.
   (d) $O^{2-} + NH_3 \rightleftharpoons OH^- + NH_2^-$
   The reaction is product-favored at equilibrium.

Study Questions

16.1 (a) CN^-, cyanide ion
(b) SO_4^{2-}, sulfate ion
(c) F^-, fluoride ion

16.3 (a) $H_3O^+(aq) + NO_3^-(aq)$; $H_3O^+(aq)$ is the conjugate acid of H_2O, and $NO_3^-(aq)$ is the conjugate base of HNO_3.
(b) $H_3O^+(aq) + SO_4^{2-}(aq)$; $H_3O^+(aq)$ is the conjugate acid of H_2O, and $SO_4^{2-}(aq)$ is the conjugate base of HSO_4^-.
(c) $H_2O + HF$; H_2O is the conjugate base of H_3O^+, and HF is the conjugate acid of F^-.

16.5 Brønsted acid: $HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + C_2O_4^{2-}(aq)$

Brønsted base: $HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_2C_2O_4(aq) + OH^-(aq)$

16.7

	Acid (A)	Base (B)	Conjugate Base of A	Conjugate Acid of B
(a)	HCO_2H	H_2O	HCO_2^-	H_3O^+
(b)	H_2S	NH_3	HS^-	NH_4^+
(c)	HSO_4^-	OH^-	SO_4^{2-}	H_2O

16.9 $[H_3O^+] = 1.8 \times 10^{-4}$ M; acidic

16.11 HCl is a strong acid, so $[H_3O^+]$ = concentration of the acid. $[H_3O^+] = 0.0075$ M and $[OH^-] = 1.3 \times 10^{-12}$ M. pH = 2.12.

16.13 $Ba(OH)_2$ is a strong base, so $[OH^-]$ = 2 × concentration of the base.

$[OH^-] = 3.0 \times 10^{-3}$ M; pOH = 2.52; and pH = 11.48

16.15 (a) The strongest acid is HCO_2H (largest K_a) and the weakest acid is C_6H_5OH (smallest K_a).
(b) The strongest acid (HCO_2H) has the weakest conjugate base.
(c) The weakest acid (C_6H_5OH) has the strongest conjugate base.

16.17 (c) HClO, the weakest acid in this list (Table 16.2), has the strongest conjugate base.

16.19 (a) HCO_3^-. Decide based on the base strength (Table 16.2). The strongest base of the three listed examples has the weakest conjugate acid.

16.21 $CO_3^{2-}(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$

16.23 Highest pH, Na_2S; lowest pH, $AlCl_3$ (which gives the weak acid $[Al(H_2O)_6]^{3+}$ in solution)

16.25 $pK_a = 4.19$

16.27 $K_a = 3.0 \times 10^{-10}$; in Table 16.2, this acid falls between hexaaquairon(II) ion and the hydrogen carbonate ion.

16.29 2-Chlorobenzoic acid is the stronger acid; it has the smaller pK_a value.

16.31 $K_b = 7.1 \times 10^{-12}$

16.33 $K_b = 6.3 \times 10^{-5}$

16.35 $CH_3CO_2H(aq) + HCO_3^-(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2CO_3(aq)$

Equilibrium lies predominantly to the right because CH_3CO_2H is a stronger acid than H_2CO_3.

16.37 (a) Left; NH_3 and HBr are the stronger base and acid, respectively.
(b) Left; PO_4^{3-} and CH_3CO_2H are the stronger base and acid, respectively.
(c) Right; $[Fe(H_2O)_6]^{3+}$ and HCO_3^- are the stronger acid and base, respectively.

16.39 (a) $OH^-(aq) + HPO_4^{2-}(aq) \rightleftharpoons H_2O(\ell) + PO_4^{3-}(aq)$
(b) OH^- is a stronger base than PO_4^{3-}, so the equilibrium will lie to the right.

16.41 (a) $CH_3CO_2H(aq) + HPO_4^{2-}(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2PO_4^-(aq)$
(b) CH_3CO_2H is a stronger acid than $H_2PO_4^-$, so the equilibrium will lie to the right.

16.43 (a) 2.1×10^{-3} M; (b) $K_a = 3.5 \times 10^{-4}$

16.45 $K_b = 6.6 \times 10^{-9}$

16.47 (a) $[H_3O^+] = 1.6 \times 10^{-4}$ M
(b) Moderately weak; $K_a = 1.1 \times 10^{-5}$

16.49 $[CH_3CO_2^-] = [H_3O^+] = 1.9 \times 10^{-3}$ M and $[CH_3CO_2H] = 0.20$ M

16.51 $[H_3O^+] = [CN^-] = 3.2 \times 10^{-6}$ M; [HCN] = 0.025 M; pH = 5.50

16.53 $[NH_4^+] = [OH^-] = 1.6 \times 10^{-3}$ M; $[NH_3]$ = 0.15 M; pH = 11.22

16.55 $[OH^-]$ = 0.010 M; pH = 12.01; pOH = 1.99

16.57 pH = 3.25

16.59 $[H_3O^+] = 1.1 \times 10^{-5}$ M; pH = 4.98

16.61 $[HCN] = [OH^-] = 3.3 \times 10^{-3}$ M; $[H_3O^+] = 3.0 \times 10^{-12}$ M; $[Na^+]$ = 0.441 M

16.63 $[H_3O^+] = 1.5 \times 10^{-9}$ M; pH = 8.81

16.65 (a) The reaction produces acetate ion, the conjugate base of acetic acid. The solution is weakly basic. pH is greater than 7.
(b) The reaction produces NH_4^+, the conjugate acid of NH_3. The solution is weakly acidic. pH is less than 7.
(c) The reaction mixes equal molar amounts of strong base and strong acid. The solution will be neutral. pH will be 7.

16.67 $H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons HC_2O_4^-(aq) + H_3O^+(aq)$
$HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons C_2O_4^{2-}(aq) + H_3O^+(aq)$

16.69 $H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons HC_2O_4^-(aq) + H_3O^+(aq)$ $K_{a1} = 5.2 \times 10^{-2}$
$HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_2C_2O_4(aq) + OH^-(aq)$ $K_{b2} = 1.9 \times 10^{-13}$
Sum: $2\ H_2O(\ell) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$ $K_w = K_{a1} \times K_{b2} = 1.0 \times 10^{-14}$

16.71 (a) pH = 1.17; (b) $[SO_3^{2-}] = 6.2 \times 10^{-8}$ M

16.73 (a) $[OH^-] = [N_2H_5^+] = 9.2 \times 10^{-5}$ M; $[N_2H_6^{2+}] = 8.9 \times 10^{-16}$ M
(b) pH = 9.96

16.75 HOCN should be a stronger acid than HCN because the H atom in HOCN is attached to the more electronegative O atom. The electron attachment enthalpy of OCN is thus more negative than that of CN, which stabilizes the conjugate base that forms and makes the ionization of HOCN more product-favored.

16.77 The S atom is surrounded by four highly electronegative O atoms. These help stabilize the conjugate base that needs to form so that the negative charge is more readily accepted.

16.79 (a) Lewis base
(b) Lewis acid
(c) Lewis base (owing to lone pair of electrons on the N atom)

16.81 CO is a Lewis base in its reactions with transition metal atoms. It donates a lone pair of electrons on the C atom.

16.83 pH = 2.671

16.85 Both $Ba(OH)_2$ and $Sr(OH)_2$ dissolve completely in water to provide M^{2+} and OH^- ions. 2.50 g $Sr(OH)_2$ in 1.00 L of water gives $[Sr^{2+}]$ = 0.021 M and $[OH^-]$ = 0.041 M. The concentration of OH^- is reflected in a pH of 12.61.

16.87 $H_2S(aq) + CH_3CO_2^-(aq) \rightleftharpoons CH_3CO_2H(aq) + HS^-(aq)$

The equilibrium lies to the left and favors the reactants.

16.89 $[X^-] = [H_3O^+] = 3.0 \times 10^{-3}$ M; [HX] = 0.007 M; pH = 2.52

16.91 $K_a = 1.4 \times 10^{-5}$; $pK_a = 4.86$

16.93 pH = 5.84

16.95 (a) Ethylamine is a stronger base than ethanolamine.
(b) For ethylamine, the pH of the solution is 11.82.

16.97 pH = 7.66

16.99 Acidic: $NaHSO_4$, NH_4Br, $FeCl_3$
Neutral: $KClO_4$, $NaNO_3$, LiBr
Basic: Na_2CO_3, $(NH_4)_2S$, Na_2HPO_4
Highest pH: $(NH_4)_2S$, lowest pH: $NaHSO_4$

16.101 $K_{net} = K_{a1} \times K_{a2} = 3.8 \times 10^{-6}$

16.103 For the reaction $HCO_2H(aq) + OH^-(aq) \rightarrow H_2O(\ell) + HCO_2^-(aq)$, $K_{net} = K_a$ (for HCO_2H) $\times [1/K_w] = 1.8 \times 10^{10}$

16.105 To double the percent ionization, you must dilute 100 mL of solution to 400 mL.

16.107 $H_2O > H_2C_2O_4 > HC_2O_4^- = H_3O^+ > C_2O_4^{2-} > OH^-$

16.109 Measure the pH of 0.1 M solutions of the three bases. The solution containing the strongest base will have the highest pH. The solution having the weakest base will have the lowest pH.

16.111 The possible cation–anion combinations are NaCl (neutral), NaOH (basic), NH_4Cl (acidic), NH_4OH (basic), HCl (acidic), and H_2O (neutral).

A = H^+ solution; B = NH_4^+ solution; C = Na^+ solution; Y = Cl^- solution; Z = OH^- solution

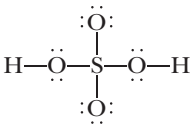
16.113 $K_a = 3.0 \times 10^{-5}$

16.115 (a) Aniline is both a Brønsted and a Lewis base. As a proton acceptor it gives $C_6H_5NH_3^+$. The N atom can also donate an electron pair to give a Lewis acid–base adduct, $F_3B \leftarrow NH_2C_6H_5$.
(b) pH = 7.97

16.117 Water can both accept a proton (a Brønsted base) and donate a lone pair (a Lewis base). Water can also donate a proton (Brønsted acid), but it cannot accept a pair of electrons (and act as a Lewis acid).

16.119 (a) HOCl is the strongest acid (smallest pK_a and largest K_a), and HOI is the weakest acid.
(b) Cl is more electronegative than Br or I, so the OCl^- anion is more stable than the other two oxoanions.

16.121 (a) $HClO_4 + H_2SO_4 \rightleftharpoons ClO_4^- + H_3SO_4^+$
(b) The O atoms on sulfuric acid have lone pairs of electrons that can be used to bind to an H^+ ion.



16.123 (a) $\left[:\ddot{I}—\ddot{I}—\ddot{I}:\right]^-$

(b) $I^-(aq)$ [Lewis base] + $I_2(aq)$ [Lewis acid] $\rightarrow I_3^-(aq)$

16.125 (a) For the weak acid HA, the concentrations at equilibrium are $[HA] = C_0 - \alpha C_0$, $[H_3O^+] = [A^-] = \alpha C_0$. Putting these into the usual expression for K_a we have $K_a = \alpha^2 C_0/(1-\alpha)$.
(b) For 0.10 M NH_4^+, $\alpha = 7.5 \times 10^{-5}$ (reflecting the fact that NH_4^+ is a much weaker acid than acetic acid).

16.127 (a) Add the three equations.

$NH_4^+(aq) + H_2O(\ell) \rightleftharpoons NH_3(aq) + H_3O^+(aq)$ $K_1 = K_w/K_b$

$CN^-(aq) + H_2O(\ell) \rightleftharpoons HCN(aq) + OH^-(aq)$ $K_2 = K_w/K_a$

$H_3O^+(aq) + OH^-(aq) \rightleftharpoons 2\ H_2O(\ell)$ $K_3 = 1/K_w$

$NH_4^+(aq) + CN^-(aq) \rightleftharpoons NH_3(aq) + HCN(aq)$ $K_{net} = K_1K_2K_3 = K_w/K_aK_b$

(b) The salts NH_4CN, $NH_4CH_3CO_2$, and NH_4F have K_{net} values of 1.4, 3.1×10^{-5}, and 7.7×10^{-7}, respectively. Only in the case of NH_4CN is the base (the cyanide ion) strong enough to remove a proton from the ammonium ion and produce a significant concentration of products.

(c) NH_4CN: basic, K_b of $CN^- > K_a$ of NH_4^+

$NH_4CH_3CO_2$: neutral, K_b of $CH_3CO_2^- = K_a$ of NH_4^+

NH_4F: acidic, K_b of F^- is less than K_a of NH_4^+

Chapter 17

Case Study

Take a Deep Breath

1. $pH = pK_a + \log[HPO_4^{2-}]/[H_2PO_4^-]$

$7.4 = 7.20 + \log[HPO_4^{2-}]/[H_2PO_4^-]$

$[HPO_4^{2-}]/[H_2PO_4^-] = 1.6$

2. Assign $x = [HPO_4^{2-}]$, then $[H_2PO_4^-] = (0.020 - x)$

$1.6 = x/(0.020 - x)$; $x = 0.012$

$[HPO_4^{2-}] = x = 0.012$ mol/L

$[H_2PO_4^-] = 0.020 - x = 0.008$ mol/L

Check Your Understanding

17.1 pH of 0.30 M HCO_2H:

$K_a = [H_3O^+][HCO_2^-]/[HCO_2H]$

$1.8 \times 10^{-4} = [x][x]/[0.30 - x]$

$x = 7.3 \times 10^{-3}$ M; pH = 2.13

pH of 0.30 M formic acid + 0.10 M $NaHCO_2$

$K_a = [H_3O^+][HCO_2^-]/[HCO_2H]$

$1.8 \times 10^{-4} = [x][0.10 + x]/(0.30 - x)$

$x = 5.4 \times 10^{-4}$ M; pH = 3.27

17.2

Equation	$HCO_2H + H_2O \rightleftharpoons H_3O^+ + HCO_2^-$		
Initial (M)	0.50	0	0.70
Change (M)	$-x$	$+x$	$+x$
Equilibrium (M)	$0.50 - x$	x	$0.70 + x$

$K_a = 1.8 \times 10^{-4} = (x)(0.70 + x)/(0.50 - x)$

The value of x will be insignificant compared to 0.50 M and 0.70 M.

$1.8 \times 10^{-4} = (x)(0.70)/(0.50)$

$x = [H_3O^+] = 1.3 \times 10^{-4}$ M

$pH = -\log[H_3O^+] = 3.89$

17.3 (15.0 g $NaHCO_3$)(1 mol/84.01 g) = 0.179 mol $NaHCO_3$, and (18.0 g Na_2CO_3)(1 mol/106.0 g) = 0.170 mol Na_2CO_3

$pH = pK_a + \log \{[base]/[acid]\}$

$pH = -\log (4.8 \times 10^{-11}) + \log \{[0.170]/[0.179]\}$

$pH = 10.32 - 0.02 = 10.30$

17.4 $pH = pK_a + \log \{[base]/[acid]\}$

$5.00 = -\log (1.8 \times 10^{-5}) + \log \{[base]/[acid]\}$

$5.00 = 4.74 + \log \{[base]/[acid]\}$

[base]/[acid] = 1.8

To prepare this buffer solution, the ratio [base]/[acid] must equal 1.8. For example, you can dissolve 1.8 mol (148 g) of $NaCH_3CO_2$ and 1.0 mol (60.05 g) of CH_3CO_2H in some amount of water.

17.5 Initial pH (before adding acid):

$pH = pK_a + \log \{[base]/[acid]\}$

$= -\log (1.8 \times 10^{-4}) + \log \{[0.70]/[0.50]\}$

$= 3.74 + 0.15 = 3.89$

After adding acid, the added HCl will react with the weak base (formate ion) and form more formic acid. The net effect is to change the ratio of [base]/[acid] in the buffer solution.

Initial amount HCO_2H = 0.50 mol/L × 0.500 L = 0.25 mol

Initial amount HCO_2^- = 0.70 mol/L × 0.50 L = 0.35 mol

Amount HCl added = 1.0 mol/L × 0.010 L = 0.010 mol

Amount HCO_2H after HCl addition = 0.25 mol + 0.010 mol = 0.26 mol

Amount HCO_2^- after HCl addition = 0.35 mol − 0.010 mol = 0.34 mol

$pH = pK_a + \log \{[base]/[acid]\}$

$pH = -\log (1.8 \times 10^{-4}) + \log \{[0.34]/[0.26]\}$

$pH = 3.74 + 0.12 = 3.86$

17.6 35.0 mL base will partially neutralize the acid.

Initial amount CH_3CO_2H = (0.100 mol/L)(0.1000 L) = 0.0100 mol

Amount NaOH added = (0.100 mol/L)(0.0350 L) = 0.00350 mol

Amount CH_3CO_2H after reaction = 0.0100 − 0.00350 = 0.0065 mol

Amount $CH_3CO_2^-$ after reaction = 0.00350 mol

$[CH_3CO_2H]$ after reaction = 0.0065 mol/0.1350 L = 0.048 M

$[CH_3CO_2^-]$ after reaction = 0.00350 mol/0.1350 L = 0.0259 M

$K_a = [H_3O^+][CH_3CO_2^-]/[CH_3CO_2H]$

$1.8 \times 10^{-5} = [x][0.0259 + x]/[0.048 - x]$

$x = [H_3O^+] = 3.3 \times 10^{-5}$ M; pH = 4.48

17.7 75.0 mL acid will partially neutralize the base.

Initial amount NH_3 = (0.100 mol/L)(0.1000 L) = 0.0100 mol

Amount HCl added = (0.100 mol/L)(0.0750 L) = 0.00750 mol

Amount NH_3 after reaction = 0.0100 − 0.00750 = 0.0025 mol

Amount NH_4^+ after reaction = 0.00750 mol

Solve using the Henderson–Hasselbalch equation; use K_a for the weak acid NH_4^+:

$pH = pK_a + \log \{[base]/[acid]\}$

$pH = -\log (5.6 \times 10^{-10}) + \log \{[0.0025]/[0.00750]\}$

$pH = 9.25 - 0.48 = 8.77$

17.8 $BaF_2(s) \rightleftharpoons Ba^{2+}(aq) + 2\ F^-(aq)$

$[F^-] = 2[Ba^{2+}] = 2(3.6 \times 10^{-3}\ M) = 7.2 \times 10^{-3}$ M

$K_{sp} = [Ba^{2+}][F^-]^2 = (3.6 \times 10^{-3})(7.2 \times 10^{-3})^2 = 1.9 \times 10^{-7}$

17.9 $AgCN(s) \rightleftharpoons Ag^+(aq) + CN^-(aq)$

$K_{sp} = [Ag^+][CN^-]$

Let x = solubility of AgCN in mol/L

$6.0 \times 10^{-17} = x^2$

$x = 7.7 \times 10^{-9}$ mol/L

$(7.7 \times 10^{-9}$ mol AgCN/L)(133.9 g AgCN/1 mol AgCN) $= 1.0 \times 10^{-6}$ g/L

17.10 $Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\ OH^-(aq)$

$K_{sp} = [Ca^{2+}][OH^-]^2$; $K_{sp} = 5.5 \times 10^{-5}$

$5.5 \times 10^{-5} = [x][2x]^2$ (where x = solubility in mol/L)

$x = 2.4 \times 10^{-2}$ mol/L

Solubility in g/L = $(2.4 \times 10^{-2}$ mol/L)(74.1 g/mol) = 1.8 g/L

17.11 (a) In pure water:

$K_{sp} = [Ba^{2+}][SO_4^{2-}]$; $1.1 \times 10^{-10} = [x][x]$;
$x = 1.0 \times 10^{-5}$ mol/L

(b) In 0.010 M $Ba(NO_3)_2$, which furnishes 0.010 M Ba^{2+} in solution:

$K_{sp} = [Ba^{2+}][SO_4^{2-}]$
$1.1 \times 10^{-10} = [0.010 + x][x]$
$x = 1.1 \times 10^{-8}$ mol/L

17.12 (a) In pure water:

$K_{sp} = [Zn^{2+}][CN^-]^2$; $8.0 \times 10^{-12} = [x][2x]^2 = 4x^3$
Solubility = $x = 1.3 \times 10^{-4}$ mol/L

(b) In 0.10 M $Zn(NO_3)_2$, which furnishes 0.10 M Zn^{2+} in solution:

$K_{sp} = [Zn^{2+}][CN^-]^2$; $8.0 \times 10^{-12} = [0.10 + x][2x]^2$
Solubility = $x = 4.5 \times 10^{-6}$ mol/L

17.13 When $[Pb^{2+}] = 1.1 \times 10^{-3}$ M, $[I^-] = 2.2 \times 10^{-3}$ M.

$Q = [Pb^{2+}][I^-]^2 = [1.1 \times 10^{-3}][2.2 \times 10^{-3}]^2 = 5.3 \times 10^{-9}$

This value is less than K_{sp}, which means that the system has not yet reached equilibrium and more PbI_2 will dissolve.

17.14 $K_{sp} = [Pb^{2+}][I^-]^2$. Let x be the concentration of I^- required at equilibrium.

$9.8 \times 10^{-9} = [0.050][x]^2$

$x = [I^-] = 4.4 \times 10^{-4}$ mol/L. A concentration greater than this value will result in precipitation of PbI_2.

Let x be the concentration of Pb^{2+} in solution, in equilibrium with 0.0015 M I^-.

$9.8 \times 10^{-9} = [x][1.5 \times 10^{-3}]^2$

$x = [Pb^{2+}] = 4.4 \times 10^{-3}$ M

17.15 First, determine the concentrations of Ag^+ and Cl^-; then calculate Q, and see whether it is greater than or less than K_{sp}. Concentrations are calculated using the final volume, 105.0 mL, in the equation $C_{dil} \times V_{dil} = C_{conc} \times V_{conc}$.

$[Ag^+](0.1050\ L) = (0.0010\ mol/L)(0.1000\ L)$

$[Ag^+] = 9.5 \times 10^{-4}$ M

$[Cl^-](0.1050\ L) = (0.025\ M)(0.0050\ L)$

$[Cl^-] = 1.2 \times 10^{-3}$ M

$Q = [Ag^+][Cl^-] = [9.5 \times 10^{-4}][1.2 \times 10^{-3}] = 1.1 \times 10^{-6}$

Because $Q > K_{sp}$, precipitation occurs.

17.16

Equation	$[Ag(NH_3)_2]^+ \rightleftharpoons$	Ag^+	+ 2 NH_3
Initial (M)	0.0050	0	1.00 − 2(0.0050)
Change	$-x$	$+x$	$+2x$
Equilibrium (M)	0.0050 − x	x	0.99 + 2x

$K = 1/K_f = 1/1.1 \times 10^7 = [x][0.99]^2/0.0050$

$x = [Ag^+] = 4.6 \times 10^{-10}$ mol/L

17.17 $Cu(OH)_2(s) \rightleftharpoons Cu^{2+}(aq) + 2\ OH^-(aq)$

$K_{sp} = [Cu^{2+}][OH^-]^2$

$Cu^{2+}(aq) + 4\ NH_3(aq) \rightleftharpoons [Cu(NH_3)_4]^{2+}(aq)$

$K_{form} = [Cu(NH_3)_4^{2+}]/[Cu^{2+}][NH_3]^4$

Net: $Cu(OH)_2(s) + 4\ NH_3(aq) \rightleftharpoons Cu(NH_3)_4^{2+}(aq) + 2\ OH^-(aq)$

$K_{net} = K_{sp} \times K_f = (2.2 \times 10^{-20})(2.1 \times 10^{13}) = 4.6 \times 10^{-7}$

17.7 pH = 9.12; pH of buffer is lower than the pH of the original solution of NH_3 (pH = 11.17).

17.9 4.7 g

17.11 pH = 4.92

17.13 $[CH_3CO_2H]/[CH_3CO_2^-] = 0.56$

17.15 (a) pH = 3.59; (b) $[HCO_2H]/[HCO_2^-] = 0.45$

17.17 (b) $NH_3 + NH_4Cl$

17.19 The buffer must have a ratio of 0.51 mol NaH_2PO_4 to 1 mol Na_2HPO_4. For example, dissolve 0.51 mol NaH_2PO_4 (61 g) and 1.0 mol Na_2HPO_4 (140 g) in some amount of water.

17.21 46 mL of 1.0 M NaOH

17.23 (a) pH = 4.95; (b) pH = 5.05

17.25 (a) pH = 9.55; (b) pH = 9.50

17.27 (a) Original pH = 5.62
(b) $[Na^+] = 0.0323$ M, $[OH^-] = 1.5 \times 10^{-3}$ M, $[H_3O^+] = 6.5 \times 10^{-12}$ M, and $[C_6H_5O^-] = 0.0308$ M
(c) pH = 11.19

17.29 (a) Original NH_3 concentration = 0.0154 M
(b) At the equivalence point $[H_3O^+] = 1.9 \times 10^{-6}$ M, $[OH^-] = 5.3 \times 10^{-9}$ M, $[NH_4^+] = 6.25 \times 10^{-3}$ M.
(c) pH at equivalence point = 5.73

17.31 The titration curve begins at pH = 13.00 and drops slowly as HCl is added. Just before the equivalence point (when 30.0 mL of acid has been added), the curve falls steeply. The pH at the equivalence point is exactly 7. Just after the equivalence point, the curve flattens again and begins to approach the final pH of just over 1.0. The total volume at the equivalence point is 60.0 mL.

17.33 (a) Starting pH = 11.12
(b) pH at equivalence point = 5.28
(c) pH at midpoint (half-neutralization point) = 9.25
(d) Methyl red, bromcresol green
(e)

Acid (mL)	Added pH
5.00	9.85
15.0	9.08
20.0	8.65
22.0	8.39
30.0	2.04

17.35 See Figure 17.10 on page 655.
(a) Thymol blue or bromphenol blue
(b) Phenolphthalein
(c) Methyl red; thymol blue

17.37 (a) Silver chloride, AgCl; lead(II) chloride, $PbCl_2$
(b) Zinc carbonate, $ZnCO_3$; zinc sulfide, ZnS
(c) Iron(II) carbonate, $FeCO_3$; iron(II) oxalate, FeC_2O_4

17.39 (a) and (b) are soluble, (c) and (d) are insoluble.

17.41 (a) $AgCN(s) \rightarrow Ag^+(aq) + CN^-(aq)$, $K_{sp} = [Ag^+][CN^-]$
(b) $NiCO_3(s) \rightarrow Ni^{2+}(aq) + CO_3^{2-}(aq)$, $K_{sp} = [Ni^{2+}][CO_3^{2-}]$
(c) $AuBr_3(s) \rightarrow Au^{3+}(aq) + 3\ Br^-(aq)$, $K_{sp} = [Au^{3+}][Br^-]^3$

17.43 $K_{sp} = (1.9 \times 10^{-3})^2 = 3.6 \times 10^{-6}$

17.45 $K_{sp} = 4.37 \times 10^{-9}$

17.47 $K_{sp} = 1.4 \times 10^{-15}$

17.49 (a) 9.2×10^{-9} M; (b) 2.2×10^{-6} g/L

17.53 Only 2.1×10^{-4} g dissolves.

17.55 (a) $PbCl_2$; (b) FeS; (c) $Fe(OH)_2$

17.57 Solubility in pure water = 1.0×10^{-6} mol/L; solubility in 0.010 M SCN^- = 1.0×10^{-10} mol/L

17.59 (a) Solubility in pure water = 2.2×10^{-6} mg/mL
(b) Solubility in 0.020 M $AgNO_3$ = 1.0×10^{-12} mg/mL

17.61 $[Fe^{2+}] = 4.9 \times 10^{-3}$ M

17.63 (a) PbS
(b) Ag_2CO_3
(c) $Al(OH)_3$

17.65 $Q < K_{sp}$, so no precipitate forms.

17.67 $Q > K_{sp}$; $Zn(OH)_2$ will precipitate.

17.69 $[OH^-]$ must exceed 1.0×10^{-5} M.

17.71 Using K_{sp} for $Zn(OH)_2$ and K_f for $[Zn(OH)_4]^{2-}$, K_{net} for

$$Zn(OH)_2(s) + 2\ OH^-(aq) \rightleftharpoons [Zn(OH)_4]^{2-}(aq)$$

is 1×10^1. This indicates that the reaction is definitely product-favored.

17.73 K_{net} for $AgCl(s) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) + Cl^-(aq)$is 2.0×10^{-3}. When all the AgCl dissolves, $[Ag(NH_3)_2^+] = [Cl^-] = 0.050$ M. To achieve these concentrations, $[NH_3]$ must be 1.12 M. Therefore, the amount of NH_3 added must be 2×0.050 mol/L (to react with the AgCl) plus 1.12 mol/L (to achieve the proper equilibrium concentration). The total is 1.22 mol/L NH_3.

17.75 (a) Solubility in pure water = 1.3×10^{-5} mol/L or 0.0019 g/L.
(b) K_{net} for $AgCl(s) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) + Cl^-(aq)$ is 2.0×10^{-3}. When using 1.0 M NH_3, the concentrations of species in solution are $[Ag(NH_3)_2]^+ = [Cl^-] = 0.041$ M and so $[NH_3] = 1.0 - 2(0.041)$ M or about 0.9 M. The amount of AgCl dissolved is 0.041 mol/L or 5.88 g/L.

17.77 (a) $NaBr(aq) + AgNO_3(aq) \rightarrow NaNO_3(aq) + AgBr(s)$
(b) $2\ KCl(aq) + Pb(NO_3)_2(aq) \rightarrow 2\ KNO_3(aq) + PbCl_2(s)$

17.79 $Q > K_{sp}$, so $BaSO_4$ precipitates.

17.81 $[H_3O^+] = 1.9 \times 10^{-10}$ M; pH = 9.73

17.83 $BaCO_3 < Ag_2CO_3 < Na_2CO_3$

17.85 Original pH = 8.62; dilution will not affect the pH.

17.87 (a) 0.100 M acetic acid has a pH of 2.87. Adding sodium acetate slowly raises the pH.
(b) Adding $NaNO_3$ to 0.100 M HNO_3 has no effect on the pH.
(c) In part (a), adding the conjugate base of a weak acid creates a buffer solution. In part (b), HNO_3 is a strong acid, but its conjugate base (NO_3^-) is so weak that the base has no effect on the complete ionization of the acid.

17.89 (a) pH = 4.13
(b) 0.6 g of $C_6H_5CO_2H$
(c) 8.2 mL of 2.0 M HCl should be added

17.91 $K = 2.1 \times 10^6$; yes, AgI forms

17.93 (a) 0.030 L (30. mL)
(b) 0.48 g CaC_2O_4

17.95 (a) $[F^-] = 1.3 \times 10^{-3}$ M
(b) $[Ca^{2+}] = 2.9 \times 10^{-5}$ M

17.97 (a) $PbSO_4$ will precipitate first.
(b) $[Pb^{2+}] = 5.1 \times 10^{-6}$ M

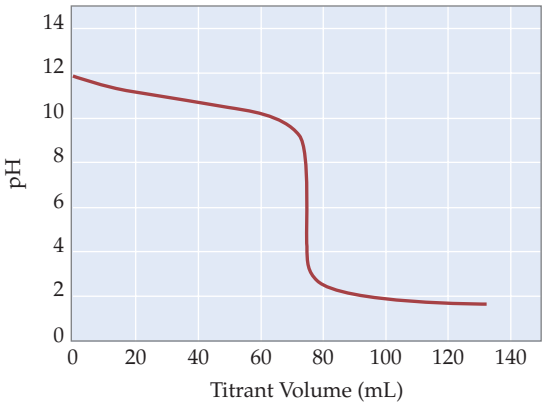
17.99 When $[CO_3^{2-}] = 0.050$ M, $[Ca^{2+}] = 6.8 \times 10^{-8}$ M. This means only 6.8×10^{-4} % of the ions remain, or that essentially all of the calcium ions have been removed.

17.101 (a) Add H_2SO_4, precipitating $BaSO_4$ and leaving $Na^+(aq)$ in solution.
(b) Add HCl or another source of chloride ion. $PbCl_2$ will precipitate, but $NiCl_2$ is water-soluble.

17.103 (a) $BaSO_4$ will precipitate first.
(b) $[Ba^{2+}] = 1.8 \times 10^{-7}$ M

17.105 (a) pH = 2.81
(b) pH at equivalence point = 8.72
(c) pH at the midpoint = pK_a = 4.62
(d) Phenolphthalein
(e) After 10.0 mL, pH = 4.39.
After 20.0 mL, pH = 5.07.
After 30.0 mL, pH = 11.84.
(f) A plot of pH versus volume of NaOH added would begin at a pH of 2.81, rise slightly to the midpoint at pH = 4.62, and then begin to rise more steeply as the equivalence point is approached (when the volume of NaOH added is 27.0 mL). The pH rises vertically through the equivalence point, and then begins to level off above a pH of about 11.0.

17.107 The K_b value for ethylamine (4.27×10^{-4}) is found in Appendix I.
(a) pH = 11.89
(b) Midpoint pH = 10.63
(c) pH = 10.15
(d) pH = 5.93 at the equivalence point
(e) pH = 2.13
(f) Titration curve



(g) Alizarin or bromcresol purple (see Figure 17.10)

17.109 110 mL NaOH

17.111 Add dilute HCl, say 1 M HCl, to a solution of the salts. Both AgCl and $PbCl_2$ will precipitate, but Cu^{2+} ions will stay in solution (as $CuCl_2$ is water-soluble). Decant off the copper-containing solution to leave a precipitate of white AgCl and $PbCl_2$. Lead(II) chloride ($K_{sp} = 1.7 \times 10^{-5}$) is much more soluble than AgCl ($K_{sp} = 1.8 \times 10^{-10}$). Warming the precipitates in water will dissolve the $PbCl_2$ and leave the AgCl as a white solid.

17.113 $Cu(OH)_2$ will dissolve in a nonoxidizing acid such as HCl, whereas CuS will not.

17.115 When Ag_3PO_4 dissolves slightly, it produces a small concentration of the phosphate ion, PO_4^{3-}. This ion is a strong base and hydrolyzes to HPO_4^{2-}. As this reaction removes the PO_4^{3-} ion from equilibrium with Ag_3PO_4, the equilibrium shifts to the right, producing more PO_4^{3-} and Ag^+ ions. Thus, Ag_3PO_4 dissolves to a greater extent than might be calculated from a K_{sp} value (unless the K_{sp} value was actually determined experimentally).

17.117 (a) Base is added to increase the pH. The added base reacts with acetic acid to form more acetate ions in the mixture. Thus, the fraction of acid declines and the fraction of conjugate base rises (i.e., the ratio $[CH_3CO_2H]/[CH_3CO_2^-]$ decreases) as the pH rises.
(b) At pH = 4, acid predominates (85% acid and 15% acetate ions). At pH = 6, acetate ions predominate (95% acetate ions and 5% acid).
(c) At the point the lines cross, $[CH_3CO_2H] = [CH_3CO_2^-]$. At this point pH = pK_a, so pK_a for acetic acid is 4.74.

17.119 (a) C—C—C angle, 120°; O—C=O, 120°; C—O—H, 109°; C—C—H, 120°
(b) Both the ring C atoms and the C in CO_2H are sp^2 hybridized.
(c) $K_a = 1 \times 10^{-3}$
(d) 10%
(e) pH at half-way point = pK_a = 3.0; pH at equivalence point = 7.3

Chapter 18

Case Study

Thermodynamics and Living Things

1. Creatine phosphate + $H_2O \rightarrow$ creatine + HP_i

$\Delta_r G° = -43.3$ kJ/mol

Adenosine + $HP_i \rightarrow$ adenosine monophosphate + H_2O

$\Delta_r G° = +9.2$ kJ/mol

Net reaction (sum of the two reactions):

Creatine phosphate + adenosine $\rightarrow$ creatine + adenosine monophosphate

For this, $\Delta_r G° = -43.3$ kJ/mol + 9.2 kJ/mol = −34.1 kJ/mol. The negative value indicates that the transfer of phosphate from creatine phosphate to adenosine is product-favored.

2. $\Delta_r G°' = \Delta_r G° + RT \ln[C][H_3O^+]/[A][B] = \Delta_r G° + (8.31 \times 10^{-3}$ kJ/mol · K)(298 K) ln[1][1×10^{-7}]/[1][1]

$\Delta_r G°' = \Delta_r G° - 39.9$ kJ/mol

Check Your Understanding

18.1 (a) O_3; larger molecules generally have higher entropies than smaller molecules.

(b) $SnCl_4(g)$; gases have higher entropies than liquids.

18.2 (a) $\Delta_r S° = \Sigma n S°(\text{products}) - \Sigma n S°(\text{reactants})$

$\Delta_r S° = (1 \text{ mol/mol-rxn}) S°[NH_4Cl(aq)]) - (1 \text{ mol/mol-rxn}) S°[NH_4Cl(s)]$

$\Delta_r S° = (1 \text{ mol/mol-rxn})(169.9 \text{ J/mol} \cdot \text{K}) - (1 \text{ mol/mol-rxn})(94.85 \text{ J/mol} \cdot \text{K})$

$= 75.1 \text{ J/K} \cdot \text{mol-rxn}$

A gain in entropy for the formation of a mixture (solution) is expected.

(b) $\Delta_r S° = (2 \text{ mol } CO_2\text{/mol-rxn}) S°(CO_2) + (3 \text{ mol } H_2O\text{/mol-rxn}) S°(H_2O) - [(1 \text{ mol } C_2H_5OH\text{/mol-rxn}) S°(C_2H_5OH) + (3 \text{ mol } O_2\text{/mol-rxn}) S°(O_2)]$

$\Delta_r S° = (2 \text{ mol/mol-rxn})(213.74 \text{ J/mol} \cdot \text{K}) + (3 \text{ mol/mol-rxn})(188.84 \text{ J/mol} \cdot \text{K}) - [(1 \text{ mol/mol-rxn})(282.70 \text{ J/mol} \cdot \text{K}) + (3 \text{ mol/mol-rxn})(205.07 \text{ J/mol} \cdot \text{K})]$

$\Delta_r S° = +96.09 \text{ J/K} \cdot \text{mol-rxn}$

An increase in entropy is expected because there is an increase in the number of moles of gases.

18.3 $\Delta S°(\text{system}) = \Delta_r S° = \Sigma n S°(\text{products}) - \Sigma n S°(\text{reactants})$

$\Delta_r S° = (2 \text{ mol HCl/mol-rxn}) S°[HCl(g)] - \{(1 \text{ mol } H_2\text{/mol-rxn}) S°[H_2(g)] + (1 \text{ mol } Cl_2\text{/mol-rxn}) S°[Cl_2(g)]\}$

$= (2 \text{ mol HCl/mol-rxn})(186.2 \text{ J/K} \cdot \text{mol HCl}) - \{(1 \text{ mol } H_2\text{/mol-rxn})(130.7 \text{ J/K} \cdot \text{mol } H_2) + (1 \text{ mol } Cl_2\text{/mol-rxn})(223.08 \text{ J/K} \cdot \text{mol } Cl_2(g)\}$

$= 18.6 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta_r H° = \Sigma n \Delta_f H°(\text{products}) - \Sigma n \Delta_f H°(\text{reactants})$

$\Delta_r H° = (2 \text{ mol HCl/mol-rxn}) \Delta_f H°[HCl(g)] - \{(1 \text{ mol } H_2\text{/mol-rxn}) \Delta_f H°[H_2(g)] + (1 \text{ mol } Cl_2\text{/mol-rxn}) \Delta_f H°[Cl_2(g)]\}$

$= (2 \text{ mol HCl/mol-rxn})(-92.31 \text{ kJ/mol HCl}) - \{(1 \text{ mol } H_2\text{/mol-rxn})(0 \text{ kJ/mol } H_2) + (1 \text{ mol } Cl_2\text{/mol-rxn})(0 \text{ kJ/mol } Cl_2(g)\}$

$= -184.62$ kJ/mol-rxn

Both $\Delta_r H°$ (< 0) and $\Delta_r S°$ (> 0) are favorable, so this reaction is predicted to be spontaneous under standard conditions.

$\Delta S°(\text{surroundings}) = -\Delta_r H°/T = -(-184.62 \text{ kJ/mol-rxn})/298.15 \text{ K} = 0.61922 \text{ kJ/K} \cdot \text{mol-rxn} = 619.22 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta S°(\text{universe}) = \Delta S°(\text{system}) + \Delta S°(\text{surroundings}) = 18.6 \text{ J/K} \cdot \text{mol-rxn} + 619.22 \text{ J/K} \cdot \text{mol-rxn} = 637.8 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta S°(\text{universe}) > 0$, so the reaction is spontaneous under standard conditions.

18.4 For the reaction $N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$:

$\Delta_r H° = (2 \text{ mol/mol-rxn}) \Delta_f H°$ for $NH_3(g) = (2 \text{ mol/mol-rxn})(-45.90 \text{ kJ/mol}) = -91.80$ kJ/mol-rxn

$\Delta_r S° = (2 \text{ mol/mol-rxn}) S°(NH_3) - [(1 \text{ mol/mol-rxn}) S°(N_2) + (3 \text{ mol/mol-rxn}) S°(H_2)]$

$\Delta_r S° = (2 \text{ mol/mol-rxn})(192.77 \text{ J/ mol} \cdot \text{K}) - [(1 \text{ mol/mol-rxn})(191.56 \text{ J/mol} \cdot \text{K}) + (3 \text{ mol/mol-rxn})(130.7 \text{ J/mol} \cdot \text{K})]$

$\Delta_r S° = -198.1 \text{ J/K} \cdot \text{mol-rxn}$ $(= -0.1981 \text{ kJ/K} \cdot \text{mol-rxn})$

$\Delta_r G° = \Delta_r H° - T\Delta_r S° = -91.80 \text{ kJ/mol-rxn} - (298 \text{ K})(-0.1981 \text{ kJ/K} \cdot \text{mol-rxn})$

$\Delta_r G° = -32.8$ kJ/mol-rxn

18.5 $SO_2(g) + \frac{1}{2}\ O_2(g) \rightarrow SO_3(g)$

$\Delta_r G° = \Sigma n \Delta_f G°(\text{products}) - \Sigma n \Delta_f G°(\text{reactants})$

$\Delta_r G° = (1 \text{ mol/mol-rxn}) \Delta_f G°[SO_3(g)] - \{(1 \text{ mol/mol-rxn}) \Delta_f G°[SO_2(g)] + (0.5 \text{ mol/mol-rxn}) \Delta_f G°[O_2(g)]\}$

$\Delta_r G° = -371.04 \text{ kJ/mol-rxn} - (-300.13 \text{ kJ/mol-rxn} + 0 \text{ kJ/mol-rxn})$

$= -70.91$ kJ/mol-rxn

18.6 $HgO(s) \rightarrow Hg(\ell) + \frac{1}{2}\ O_2(g)$; determine the temperature at which $\Delta_r G° = \Delta_r H° - T\Delta_r S° = 0$. T is the unknown in this problem.

$\Delta_r H° = [-\Delta_f H°$ for $HgO(s)] = 90.83$ kJ/mol-rxn

$\Delta_r S° = S°[Hg(\ell)] + \frac{1}{2}\ S°[O_2(g)] - S°[HgO(s)]$

$\Delta_r S° = (1 \text{ mol/mol-rxn})(76.02 \text{ J/mol} \cdot \text{K}) + [(0.5 \text{ mol/mol-rxn})(205.07 \text{ J/mol} \cdot \text{K}) - (1 \text{ mol/mol-rxn})(70.29 \text{ J/mol} \cdot \text{K})]$

$= 108.27 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta_r H° - T(\Delta_r S°) = 0 = 90{,}830 \text{ J/mol-rxn} - T(108.27 \text{ J/K} \cdot \text{mol-rxn})$

$T = 839$ K (566 °C)

18.7 $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

$\Delta_r G° = \Sigma n\Delta_f G°(\text{products}) - \Sigma n\Delta_f G°(\text{reactants})$

$\Delta_r G° = \Delta_f G°(CaO) + \Delta_f G°(CO_2) - \Delta_f G°(CaCO_3)$

$\Delta_r G° = (1 \text{ mol CaO/mol-rxn})(-603.42 \text{ kJ/mol CaO}) + (1 \text{ mol } CO_2\text{/mol-rxn})(-394.359 \text{ kJ/mol } CO_2) - (1 \text{ mol } CaCO_3\text{/mol-rxn})(-1129.16 \text{ kJ/mol } CaCO_3)$

$\Delta_r G° = 131.38 \text{ kJ/mol-rxn}$

$\Delta_r G° = -RT \ln K$

$131{,}380 \text{ J/mol-rxn} = -(8.3145 \text{ J/mol-rxn} \cdot \text{K})(298.15 \text{ K})(\ln K)$

$K_p = 9.62 \times 10^{-24}$

18.8 $C(s) + CO_2(g) \rightleftharpoons 2\ CO(g)$

$\Delta_r G° = \Sigma\ n\Delta_f G°(\text{products}) - \Sigma\ n\Delta_f G°(\text{reactants})$

$\Delta_r G° = 2\ \Delta_f G°(CO) - \Delta_f G°(CO_2)$

$\Delta_r G° = (2 \text{ mol/mol-rxn})(-137.17 \text{ kJ/mol}) - (1 \text{ mol/mol-rxn})(-394.36 \text{ kJ/mol})$

$\Delta_r G° = 120.02 \text{ kJ/mol-rxn}$

$\Delta_r G° = -RT \ln K$

$120{,}020 \text{ J/mol-rxn} = -(8.3145 \text{ J/mol-rxn} \cdot \text{K})(298.15 \text{ K})(\ln K)$

$K = 9.41 \times 10^{-22}$

18.9 (a) $\Delta_r G° = 2\ \Delta_f G°(NO) = 2 \text{ mol/mol-rxn} \times 86.58 \text{ kJ/mol} = 173.2 \text{ kJ/mol-rxn}$

The reaction is reactant-favored at equilibrium.

(b) $\Delta_r G = \Delta_r G° + RT \ln Q = 173.2 \text{ kJ/mol-rxn} + (0.0083145 \text{ kJ/K} \cdot \text{mol-rxn})(298.15 \text{ K}) \ln[P(NO)]^2/[P(N_2)][P(O_2)]$

$\Delta_r G = 173.2 \text{ kJ/mol-rxn} - 11.4 \text{ kJ/mol-rxn} = 161.8 \text{ kJ/mol-rxn}$. The reaction is not spontaneous.

Review & Check

Section 18-1

1. (b) toward equilibrium

2. (b) false

3. (b) sometimes spontaneous

Section 18-2

1. (c) > 0

2. (c) dispersed

Applying Chemical Principles: Are Diamonds Forever?

1. C(diamond) → C(graphite)

(a) $\Delta_r G° = -2.900$ kJ/mol-rxn; $K = 3.22$

(b) $\Delta_r H° = -1.8$ kJ/mol-rxn; $\Delta_r S° = 3.2$ J/K · mol-rxn = 0.0032 kJ/K · mol; $\Delta_r G° = -5.0$ kJ/mol-rxn; $K = 1.8$
Though still favoring graphite, the equilibrium has shifted more toward diamond.

(c) Greater pressures favor the formation of diamond, which is more dense than graphite.

(d) The rate of reaction is negligibly slow at room temperature.

Study Questions

18.1 (a) For a given substance at a given temperature, a gas always has a greater entropy than the liquid. Matter and energy are more dispersed.

(b) Liquid water at 50 °C

(c) Ruby

(d) One mole of N_2 at 1 bar

18.3 (a) $\Delta_r S° = +12.7$ J/K · mol-rxn. Entropy increases.

(b) $\Delta_r S° = -102.56$ J/K · mol-rxn. Significant decrease in entropy.

(c) $\Delta_r S° = +93.3$ J/K · mol-rxn. Entropy increases.

(d) $\Delta_r S° = -129.7$ J/K · mol-rxn. The solution has a smaller entropy (with H^+ forming H_3O^+ and hydrogen bonding occurring) than HCl in the gaseous state.

18.5 (a) $\Delta_r S° = +9.3$ J/K · mol-rxn

(b) $\Delta_r S° = -294.0$ J/K · mol-rxn

18.7 (a) $\Delta_r S° = -507.3$ J/K · mol-rxn; entropy declines as a gaseous reactant is incorporated in a solid compound.

(b) $\Delta_r S° = +313.25$ J/K · mol-rxn; entropy increases as five molecules (three of them in the gas phase) form six molecules of products (all gases).

18.9 $\Delta S°(\text{system}) = -134.2$ J/K · mol-rxn; $\Delta H°(\text{system}) = -662.75$ kJ/mol-rxn; $\Delta S°(\text{surroundings}) = +2222.9$ J/K · mol-rxn; $\Delta S°(\text{universe}) = +2088.8$ J/K · mol-rxn. The reaction is spontaneous under standard conditions.

18.11 $\Delta S°$(system) = +163.3 J/K · mol-rxn; $\Delta H°$(system) = +285.83 kJ/mol-rxn; $\Delta S°$(surroundings) = −958.68 J/K · mol-rxn; $\Delta S°$(universe) = −795.4 J/K · mol-rxn

The reaction is not spontaneous because the overall entropy change in the universe is negative. The reaction is disfavored by energy dispersal.

18.13 (a) Type 2. The reaction is enthalpy-favored but entropy-disfavored. It is more favorable at low temperatures.
(b) Type 4. This endothermic reaction is not favored by the enthalpy change nor is it favored by the entropy change. It is not spontaneous under standard conditions at any temperature.

18.15 (a) $\Delta_r H°$ = −438 kJ/mol-rxn; $\Delta_r S°$ = −201.7 J/K · mol-rxn; $\Delta_r G°$ = −378 kJ/mol-rxn. The reaction is product-favored at equilibrium and is enthalpy-driven.
(b) $\Delta_r H°$ = −86.61 kJ/mol-rxn; $\Delta_r S°$ = −79.4 J/K · mol-rxn; $\Delta_r G°$ = −62.9 kJ/mol-rxn. The reaction is product-favored at equilibrium. The enthalpy change favors the reaction.

18.17 (a) $\Delta_r H°$ = +116.7 kJ/mol-rxn; $\Delta_r S°$ = +168.0 J/K · mol-rxn; $\Delta_f G°$ = +66.6 kJ/mol
(b) $\Delta_r H°$ = −425.93 kJ/mol-rxn; $\Delta_r S°$ = −154.6 J/K · mol-rxn; $\Delta_f G°$ = −379.82 kJ/mol
(c) $\Delta_r H°$ = +17.51 kJ/mol-rxn; $\Delta_r S°$ = +77.95 J/K · mol-rxn; $\Delta_f G°$ = −5.73 kJ/mol

The reactions in (b) and (c) are predicted to be product-favored under standard conditions.

18.19 (a) $\Delta_r G°$ = −817.54 kJ/mol-rxn; product-favored
(b) $\Delta_r G°$ = +256.6 kJ/mol-rxn; reactant-favored
(c) $\Delta_r G°$ = −1101.14 kJ/mol-rxn; product-favored

18.21 $\Delta_f G°$ [$BaCO_3$(s)] = −1134.4 kJ/mol

18.23 (a) $\Delta_r H°$ = +66.2 kJ/mol-rxn; $\Delta_r S°$ = −121.62 J/K · mol-rxn; $\Delta_r G°$ = +102.5 kJ/mol-rxn

Both the enthalpy and the entropy changes are unfavorable. There is no temperature at which the reaction will be product-favored at equilibrium. This is a case like that in the right panel in Figure 18.11 and is a Type 4 reaction (Table 18.1). As the temperature increases, the reaction becomes even more reactant-favored (the value of $\Delta_r G°$ becomes more positive).

(b) $\Delta_r H°$ = −221.05 kJ/mol-rxn; $\Delta_r S°$ = +179.1 J/K · mol-rxn; $\Delta_r G°$ = −274.45 kJ/mol-rxn

The reaction is favored by both enthalpy and entropy and is product-favored at all temperatures. This is a case like that in the left panel in Figure 18.11 and is a Type 1 reaction. As the temperature increases, the reaction becomes even more product-favored (the value of $\Delta_r G°$ becomes more negative).

(c) $\Delta_r H°$ = −179.0 kJ/mol-rxn; $\Delta_r S°$ = −160.2 J/K · mol-rxn; $\Delta_r G°$ = −131.23 kJ/mol-rxn

The reaction is favored by the enthalpy change but disfavored by the entropy change. The reaction becomes less product-favored as the temperature increases; it is a case like the red line in the middle panel of Figure 18.11.

(d) $\Delta_r H°$ = +822.2 kJ/mol-rxn; $\Delta_r S°$ = +181.28 J/K · mol-rxn; $\Delta_r G°$ = +768.19 kJ/mol-rxn

The reaction is not favored by the enthalpy change but favored by the entropy change. The reaction becomes more product-favored as the temperature increases; it is a case like the blue line in the middle panel of Figure 18.11.

18.25 (a) $\Delta_r S°$ = +174.75 J/K · mol-rxn; $\Delta_r H°$ = +116.94 kJ/mol-rxn
(b) $\Delta_r G°$ = +64.84 kJ/mol-rxn. The reaction is not product-favored under standard conditions at 298.15 K.
(c) As the temperature increases, $\Delta_r S°$ becomes more important, so $\Delta_r G°$ can become negative at a sufficiently high temperature and the reaction is product-favored.

18.27 $K_p = 6.8 \times 10^{-16}$. Note that K_p is very small and that $\Delta G°$ is positive. Both indicate a process that is reactant-favored at equilibrium.

18.29 $\Delta_r G°$ = −100.24 kJ/mol-rxn and $K_p = 3.6 \times 10^{17}$. Both the free energy change and K indicate a process that is product-favored at equilibrium.

18.31 (a) $\Delta_r G°$ = −32.74 kJ/mol-rxn. The reaction is product-favored at equilibrium.
(b) $\Delta_r G$ = −21.33 kJ/mol-rxn. The reaction is spontaneous in the forward direction.

18.33 (a) HBr(g)
(b) NH_4Cl(aq)
(c) C_2H_4(g)
(d) NaCl(g)

18.35 $\Delta_r G°$ = −98.9 kJ/mol-rxn. The reaction is product-favored at equilibrium. It is enthalpy-driven.

18.37 $\Delta_r H°$ = −1428.66 kJ/mol-rxn; $\Delta_r S°$ = +47.1 J/K · mol-rxn; $\Delta S°$(universe) = +4840 J/K · mol-rxn. Combustion reactions are spontaneous, and this is confirmed by the sign of $\Delta S°$(universe).

18.39 (a) The reaction occurs spontaneously and is product-favored. Therefore, $\Delta S°$(universe) is positive and $\Delta_r G°$ is negative. The reaction is likely to be exothermic, so $\Delta_r H°$ is negative, and $\Delta S°$(surroundings) is positive. $\Delta S°$(system) is expected to be negative because two moles of gas form one mole of solid. The calculated values are as follows:

$\Delta S°$(system) = −284.1 J/K · mol-rxn

$\Delta_r H°$ = −176.34 kJ/mol-rxn

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Copyright 2015 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

$\Delta S°$(surroundings) = +591.45 J/K · mol-rxn

$\Delta S°$(universe) = +307.4 J/K · mol-rxn

$\Delta_r G°$ = −91.64 kJ/mol-rxn

(b) $K_p = 1.1 \times 10^{16}$

18.41 $K_p = 1.3 \times 10^{29}$ at 298 K ($\Delta G° = -166.1$ kJ/mol-rxn). The reaction is already extremely product-favored at 298 K. A higher temperature would make the reaction less product-favored because $\Delta_r S°$ has a negative value (−242.3 J/K · mol-rxn).

18.43 At the boiling point, $\Delta G° = 0 = \Delta H° - T\Delta S°$.

Here $\Delta S° = \Delta H°/T$ = 112 J/K · mol-rxn at 351.15 K.

18.45 $\Delta_r S°$ is +137.2 J/K · mol-rxn. A positive entropy change means that raising the temperature will increase the product favorability of the reaction (because $T\Delta S°$ will become more negative).

18.47 The reaction is exothermic, so $\Delta_r H°$ should be negative. Also, a gas and an aqueous solution are formed, so $\Delta_r S°$ should be positive. The calculated values are $\Delta_r H°$ = −183.32 kJ/mol-rxn (with a negative sign as expected) and $\Delta_r S°$ = −7.7 J/K · mol-rxn

The entropy change is slightly negative, not positive as predicted. The reason for this is the negative entropy change upon dissolving NaOH. Apparently the OH^- ions in water hydrogen-bond with water molecules, an effect that also leads to a small, negative entropy change.

18.49 $\Delta_r H°$ = +126.03 kJ/mol-rxn; $\Delta_r S°$ = +78.2 J/K · mol-rxn; and $\Delta_r G°$ = +103 kJ/mol-rxn. The reaction is not product-favored at equilibrium.

18.51 $\Delta_r G°$ from K value = 4.87 kJ/mol-rxn

$\Delta_r G°$ from free energies of formation = 4.73 kJ/mol-rxn

18.53 $\Delta_r G°$ = −2.27 kJ/mol-rxn

18.55 (a) $\Delta_r G°$ = +141.82 kJ/mol-rxn, so the reaction is not product-favored at equilibrium.

(b) $\Delta_r H°$ = +197.86 kJ/mol-rxn; $\Delta_r S°$ = +187.95 J/K · mol-rxn

$T = \Delta_r H°/\Delta_r S°$ = 1052.7 K or 779.6 °C

(c) $\Delta_r G°$ at 1500 °C (1773 K) = −135.4 kJ/mol-rxn

K_p at 1500 °C = 1×10^4

18.57 $\Delta_r S°$ = −459.0 J/K · mol-rxn; $\Delta_r H°$ = −793 kJ/mol-rxn; $\Delta_r G°$ = −657 kJ/mol-rxn

The reaction is product-favored at equilibrium. It is enthalpy-driven.

18.59 (a) $\Delta_r G°$ at 80.0 °C = +0.14 kJ/mol-rxn

$\Delta_r G°$ at 110.0 °C = −0.12 kJ/mol-rxn

Rhombic sulfur is more stable than monoclinic sulfur at 80 °C, but the reverse is true at 110 °C.

(b) T = 370 K or about 96 °C. This is the temperature at which the two forms are at equilibrium under standard conditions.

18.61 $\Delta_r G°$ at 298 K = 22.64 kJ/mol; reaction is not product-favored at equilibrium. It does become product-favored above 469 K (196 °C).

18.63 $\Delta_f G°$ [HI(g)] = −10.9 kJ/mol

18.65 (a) $\Delta_r G°$ = +194.8 kJ/mol-rxn and $K = 6.7 \times 10^{-11}$

(b) The reaction is reactant-favored at equilibrium at 727 °C.

(c) Keep the pressure of CO as low as possible (by removing it during the course of the reaction).

18.67 $K_p = P_{Hg(g)}$ at any temperature

K_p = 1 at 620.3 K or 347.2 °C when $P_{Hg(g)}$ = 1.000 bar

T when $P_{Hg(g)}$ = (1/760) bar is 398.3 K or 125.2 °C.

18.69 (a) True

(b) False. Whether an exothermic system is spontaneous also depends on the entropy change for the system.

(c) False. Reactions with $+\Delta_r H°$ and $+\Delta_r S°$ are product-favored at higher temperatures.

(d) True

18.71 Dissolving a solid such as NaCl in water is a product-favored process. Thus, $\Delta G° < 0$. If $\Delta H° = 0$, then the only way the free energy change can be negative is if $\Delta S°$ is positive. Generally the entropy change is the important factor in forming a solution.

18.73 $2\ C_2H_6(g) + 7\ O_2(g) \rightarrow 4\ CO_2(g) + 6\ H_2O(g)$

(a) Not only is this an exothermic combustion reaction, but there is also an increase in the number of molecules of gases from reactants to products. Therefore, we would predict a positive value for $\Delta S°$ for both the system and the surroundings and thus for the universe as well.

(b) The exothermic reaction has $\Delta_r H° < 0$. Combined with a positive $\Delta S°$(system), the value of $\Delta_r G°$ is negative.

(c) The value of K_p is likely to be much greater than 1. Further, because $\Delta S°$(system) is positive, the value of K_p will be even larger at a higher temperature. (See the left panel of Figure 18.11.)

18.75 Reaction 1: $\Delta_r S°_1$ = −80.7 J/K · mol-rxn

Reaction 2: $\Delta_r S°_2$ = −161.60 J/K · mol-rxn

Reaction 3: $\Delta_r S°_3$ = −242.3 J/K · mol-rxn

$\Delta_r S°_1 + \Delta_r S°_2 = \Delta_r S°_3$; entropy is a state function.

18.77 (a) $\Delta_r H°$ = −352.88 kJ/mol-rxn and $\Delta_r S°$ = +21.31 J/K · mol-rxn. Therefore, at 298 K, $\Delta_r G°$ = −359.23 kJ/mol-rxn.

(b) 4.8 g of Mg is required.

18.79 (a) $N_2H_4(\ell) + O_2(g) \rightarrow 2\ H_2O(\ell) + N_2(g)$

O_2 is the oxidizing agent and N_2H_4 is the reducing agent.

(b) $\Delta_r H°$ = −622.29 kJ/mol-rxn and $\Delta_r S°$ = +4.87 J/K · mol-rxn. Therefore, at 298 K, $\Delta_r G°$ = −623.74 kJ/mol-rxn.

(c) 0.0027 K

(d) 7.5 mol O_2

(e) 4.8×10^3 g solution

(f) 7.5 mol $N_2(g)$ occupies 170 L at 273 K and 1.0 atm of pressure.

18.81 Iodine dissolves readily, so the process is product-favored and $\Delta G°$ must be less than zero. Because $\Delta H° = 0$, the process is entropy-driven.

18.83 $CH_3OH(g) \rightarrow C(s, \text{graphite}) + 2\ H_2(g) + 1/2\ O_2(g)$

(a) The reaction becomes more product-favored at equilibrium as temperature increases.

(b) There is no temperature between 400 K and 1000 K at which the decomposition is product-favored at equilibrium.

18.85 (a) For the electrolysis of water: $\Delta_r G° = 474.3$ kJ.
For the formation from methane: $\Delta_r G° = 142.2$ kJ.

(b) For the electrolysis of water:
$\Delta_r G° = 237.2$ kJ/mol H_2
For the formation from methane:
$\Delta_r G° = 47.4$ kJ/mol H_2

(c) The free energy change for the formation of H_2 from methane is clearly less than that to obtain H_2 from water electrolysis.

18.87 (a, b)

Temperature (K)	$\Delta_r G°$ (kJ/mol)	K
298.0 K	−32.74	5.5×10^5
800.0 K	+72.9	2×10^{-5}
1300. K	+184.0	4.0×10^{-8}

(c) The largest mole fraction of NH_3 in an equilibrium mixture will be at 298 K.

Chapter 19

Case Study

Manganese in the Oceans

1. Cathode reaction: $Mn^{3+} + e^- \rightarrow Mn^{2+}$

Anode reaction: $Mn^{3+} + 2\ H_2O \rightarrow MnO_2 + 4\ H^+ + e^-$

Net reaction: $2\ Mn^{3+} + 2\ H_2O \rightarrow MnO_2 + Mn^{2+} + 4\ H^+$

$E°_{cell} = E°(\text{cathode}) - E°(\text{anode}) =$
$1.50\ V - 0.95\ V = 0.55\ V$

The cell potential associated with this disproportionation is positive, indicating a product-favored reaction at equilibrium.

2. (a) $MnO_2 + HS^- + 3\ H^+ \rightarrow Mn^{2+} + S + 2\ H_2O$
(b) $2\ Mn^{2+} + O_2 + 2\ H_2O \rightarrow 2\ MnO_2 + 4\ H^+$

3. Cathode reaction: $O_2 + 4\ H^+ + 4\ e^- \rightarrow 2\ H_2O$ ($E° = 1.229$ V)

Anode reaction: $Mn^{2+} + 2\ H_2O \rightarrow MnO_2 + 4\ H^+ + 2\ e^-$ ($E° = 1.23$ V, from Appendix M)

$E°_{cell} = E°(\text{cathode}) - E°(\text{anode}) =$
$1.229\ V - 1.23\ V = 0\ V.$

Check Your Understanding

19.1 Oxidation half-reaction: $Al(s) \rightarrow Al^{3+}(aq) + 3\ e^-$

Reduction half-reaction: $2\ H^+(aq) + 2\ e^- \rightarrow H_2(g)$

Overall reaction: $2\ Al(s) + 6\ H^+(aq) \rightarrow 2\ Al^{3+}(aq) + 3\ H_2(g)$

Al is the reducing agent and is oxidized; $H^+(aq)$ is the oxidizing agent and is reduced.

19.2 (1) $2\ VO^{2+}(aq) + Zn(s) + 4\ H^+(aq) \rightarrow Zn^{2+}(aq) + 2\ V^{3+}(aq) + 2\ H_2O(\ell)$

$2\ V^{3+}(aq) + Zn(s) \rightarrow 2\ V^{2+}(aq) + Zn^{2+}(aq)$

(2) Oxidation (Fe^{2+}, the reducing agent, is oxidized):

$Fe^{2+}(aq) \rightarrow Fe^{3+}(aq) + e^-$

Reduction (MnO_4^-, the oxidizing agent, is reduced)

$MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)$

Overall reaction:

$MnO_4^-(aq) + 8\ H^+(aq) + 5\ Fe^{2+}(aq) \rightarrow Mn^{2+}(aq) + 5\ Fe^{3+}(aq) + 4\ H_2O(\ell)$

19.3 (a) Oxidation half-reaction:

$Al(s) + 3\ OH^-(aq) \rightarrow Al(OH)_3(s) + 3\ e^-$

Reduction half-reaction:

$S(s) + H_2O(\ell) + 2\ e^- \rightarrow HS^-(aq) + OH^-(aq)$

Overall reaction:

$2\ Al(s) + 3\ S(s) + 3\ H_2O(\ell) + 3\ OH^-(aq) \rightarrow 2\ Al(OH)_3(s) + 3\ HS^-(aq)$

(b) Aluminum is the reducing agent and is oxidized; sulfur is the oxidizing agent and is reduced.

19.4 Construct two half-cells, the first with a silver electrode and a solution containing $Ag^+(aq)$, and the second with a nickel electrode and a solution containing $Ni^{2+}(aq)$. Connect the two half-cells with a salt bridge. When the electrodes are connected through an external circuit, electrons will flow from the anode (the nickel electrode) to the cathode (the silver electrode). The overall cell reaction is $Ni(s) + 2\ Ag^+(aq) \rightarrow Ni^{2+}(aq) + 2\ Ag(s)$. To maintain electrical neutrality in the two half-cells, negative ions will flow from the $Ag|Ag^+$ half-cell to the $Ni|Ni^{2+}$ half-cell, and positive ions will flow in the opposite direction.

19.5 $Zn(s)|Zn^{2+}(aq)\|SO_4^{2-}|PbSO_4(s)|Pb(s)$

19.6 (a) Using Appendix M, the order determined for these metals from least strong reducing agent to strongest reducing agent is Hg < Pb < Sn. (The further down the table, the stronger the metal is as a reducing agent.)

(b) F_2, Cl_2, and Br_2 all can oxidize mercury to mercury(II); Hg is located "southeast" of them on the table. I_2 cannot oxidize mercury to mercury(II); mercury is located "northeast" rather than "southeast" of it.

19.7 Overall reaction: $2\ Al(s) + 3\ Fe^{2+}(aq) \rightarrow 2\ Al^{3+}(aq) + 3\ Fe(s)$

($E°_{cell} = 1.22$ V, $n = 6$)

$E_{cell} = E°_{cell} - (0.0257/n)\ \ln\{[Al^{3+}]^2/[Fe^{2+}]^3\}$
$= 1.22 - (0.0257/6)\ \ln\{[0.025]^2/[0.50]^3\}$
$= 1.22\ V - (-0.023)\ V = 1.24\ V$

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

19.8 Overall reaction: $Fe(s) + 2\ H^+(aq) \rightarrow Fe^{2+}(aq) + H_2(g)$

($E°_{cell} = 0.44$ V, $n = 2$)

$E_{cell} = E°_{cell} - (0.0257/n)\ \ln\ \{[Fe^{2+}]P_{H_2}/[H^+]^2\}$
$= 0.44 - (0.0257/2)\ \ln\ \{[0.024]1.0/[0.056]^2\}$
$= 0.44\ V - 0.026\ V = 0.41\ V$

19.9 $\Delta_r G° = -nFE°$
$= -(2\ mol\ e^-)(96{,}500\ C/mol\ e^-)$
$(-0.76\ V)(1\ J/1\ C \cdot V)$
$= 146{,}680\ J = 150\ kJ$

The negative value of $E°$ and the positive value of $\Delta G°$ both indicate a reactant-favored reaction at equilibrium.

19.10 $E°_{cell} = E°_{cathode} - E°_{anode} = 0.799\ V - 0.855\ V = -0.056\ V$; $n = 2$

$E° = (0.0257/n)\ \ln\ K$

$-0.056 = (0.0257/2)\ \ln\ K$

$K = 0.013$

19.11 Cathode: $2\ H_2O(\ell) + 2\ e^- \rightarrow 2\ OH^-(aq) + H_2(g)$

$E°_{cathode} = -0.83$ V

Anode: $4\ OH^-(aq) \rightarrow O_2(g) + 2\ H_2O(\ell) + 4\ e^-$

$E°_{anode} = 0.40$ V

Overall: $2\ H_2O(\ell) \rightarrow 2\ H_2(g) + O_2(g)$

$E°_{cell} = E°_{cathode} - E°_{anode} = -0.83\ V - 0.40\ V = -1.23\ V$

The minimum voltage needed under standard conditions to cause this reaction to occur is 1.23 V.

19.12 (1) O_2 is formed at the anode, by the reaction

$$2\ H_2O(\ell) \rightarrow 4\ H^+(aq) + O_2(g) + 4\ e^-.$$

$(0.445\ A)(45\ min)(60\ s/min)(1\ C/1\ A \cdot s)$
$(1\ mol\ e^-/96{,}500\ C)(1\ mol\ O_2/4\ mol\ e^-)$
$(32\ g\ O_2/1\ mol\ O_2) = 0.10\ g\ O_2$

(2) The cathode reaction (electrolysis of molten NaCl) is

$$Na^+(melt) + e^- \rightarrow Na(\ell).$$

$(25 \times 10^3\ A)(60\ min)(60\ s/min)(1\ C/1\ A \cdot s)$
$(1\ mol\ e^-/96{,}500\ C)(1\ mol\ Na/mol\ e^-)(23\ g\ Na/1\ mol\ Na) = 21{,}450\ g\ Na = 21\ kg$

Review & Check

Section 19-1

1. (a) CuS

2. (d) $4\ H^+ + 3\ e^- + NO_3^- \rightarrow NO + 2\ H_2O$

3. (b) $12\ OH^- + Br_2 \rightarrow 2\ BrO_3^- + 6\ H_2O + 10\ e^-$

Section 19-2

1. (b) Electrons transfer from Cd to Ni.

2. (a) Cd is the anode and is negative.

3. (b) NO_3^- ions move from the Ni half-cell to the Cd half-cell, and K^+ ions move from the Cd half-cell to the Ni half-cell.

Section 19-3

1. (b) Lead(IV) oxide is reduced.

2. (b) Sulfuric acid is consumed.

Applying Chemical Principles: Sacrifice!

1. An insulator will prevent the flow of electrons from the zinc to copper, preventing zinc from keeping the copper reduced.

3. (e) chromium

5. (a) $Cu(OH)_2(s) + 2\ e^- \rightarrow Cu(s) + 2\ OH^-(aq)$
(b) $Zn(s) + 2\ OH^-(aq) \rightarrow Zn(OH)_2(s) + 2\ e^-$
(c) $Cu(OH)_2(s) + Zn(s) \rightarrow Cu(s) + Zn(OH)_2(s)$
(d) $E = 0.89$ V

Study Questions

19.1 (a) $Cr(s) \rightarrow Cr^{3+}(aq) + 3\ e^-$

Cr is a reducing agent; this is an oxidation reaction.

(b) $AsH_3(g) \rightarrow As(s) + 3\ H^+(aq) + 3\ e^-$

AsH_3 is a reducing agent; this is an oxidation reaction.

(c) $VO_3^-(aq) + 6\ H^+(aq) + 3\ e^- \rightarrow V^{2+}(aq) + 3\ H_2O(\ell)$

$VO_3^-(aq)$ is an oxidizing agent; this is a reduction reaction.

(d) $2\ Ag(s) + 2\ OH^-(aq) \rightarrow Ag_2O(s) + H_2O(\ell) + 2e^-$

Silver is a reducing agent; this is an oxidation reaction.

19.3 (a) $Ag(s) \rightarrow Ag^+(aq) + e^-$

$e^- + NO_3^-(aq) + 2\ H^+(aq) \rightarrow NO_2(g) + H_2O(\ell)$

$Ag(s) + NO_3^-(aq) + 2\ H^+(aq) \rightarrow Ag^+(aq) + NO_2(g) + H_2O(\ell)$

(b) $2[MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)]$

$5[HSO_3^-(aq) + H_2O(\ell) \rightarrow SO_4^{2-}(aq) + 3\ H^+(aq) + 2\ e^-]$

$2\ MnO_4^-(aq) + H^+(aq) + 5\ HSO_3^-(aq) \rightarrow 2\ Mn^{2+}(aq) + 3\ H_2O(\ell) + 5\ SO_4^{2-}(aq)$

(c) $4[Zn(s) \rightarrow Zn^{2+}(aq) + 2\ e^-]$

$2\ NO_3^-(aq) + 10\ H^+(aq) + 8\ e^- \rightarrow N_2O(g) + 5\ H_2O(\ell)$

$4\ Zn(s) + 2\ NO_3^-(aq) + 10\ H^+(aq) \rightarrow 4\ Zn^{2+}(aq) + N_2O(g) + 5\ H_2O(\ell)$

(d) $Cr(s) \rightarrow Cr^{3+}(aq) + 3\ e^-$

$3\ e^- + NO_3^-(aq) + 4\ H^+(aq) \rightarrow NO(g) + 2\ H_2O(\ell)$

$Cr(s) + NO_3^-(aq) + 4\ H^+(aq) \rightarrow Cr^{3+}(aq) + NO(g) + 2\ H_2O(\ell)$

19.5 (a) $2[Al(s) + 4\ OH^-(aq) \rightarrow Al(OH)_4^-(aq) + 3\ e^-]$

$3[2\ H_2O(\ell) + 2\ e^- \rightarrow H_2(g) + 2\ OH^-(aq)]$

$2\ Al(s) + 2\ OH^-(aq) + 6\ H_2O(\ell) \rightarrow 2\ Al(OH)_4^-(aq) + 3\ H_2(g)$

(b) $2[CrO_4^{2-}(aq) + 4\ H_2O(\ell) + 3\ e^- \rightarrow Cr(OH)_3(s) + 5\ OH^-(aq)]$

$3[SO_3^{2-}(aq) + 2\ OH^-(aq) \rightarrow SO_4^{2-}(aq) + H_2O(\ell) + 2\ e^-]$

$2\ CrO_4^{2-}(aq) + 3\ SO_3^{2-}(aq) + 5\ H_2O(\ell) \rightarrow 2\ Cr(OH)_3(s) + 3\ SO_4^{2-}(aq) + 4\ OH^-(aq)$

(c) $Zn(s) + 4\ OH^-(aq) \rightarrow [Zn(OH)_4]^{2-}(aq) + 2\ e^-$

$Cu(OH)_2(s) + 2\ e^- \rightarrow Cu(s) + 2\ OH^-(aq)$

$Zn(s) + 2\ OH^-(aq) + Cu(OH)_2(s) \rightarrow [Zn(OH)_4]^{2-}(aq) + Cu(s)$

(d) $3[HS^-(aq) + OH^-(aq) \rightarrow S(s) + H_2O(\ell) + 2\ e^-]$

$ClO_3^-(aq) + 3\ H_2O(\ell) + 6\ e^- \rightarrow Cl^-(aq) + 6\ OH^-(aq)$

$3\ HS^-(aq) + ClO_3^-(aq) \rightarrow 3\ S(s) + Cl^-(aq) + 3\ OH^-(aq)$

19.7 Electrons flow from the Cr electrode to the Fe electrode. Negative ions move via the salt bridge from the Fe/Fe^{2+} half-cell to the Cr/Cr^{3+} half-cell (and positive ions move in the opposite direction).

Anode (oxidation): $Cr(s) \rightarrow Cr^{3+}(aq) + 3\ e^-$

Cathode (reduction): $Fe^{2+}(aq) + 2\ e^- \rightarrow Fe(s)$

19.9 (a) Oxidation: $Fe(s) \rightarrow Fe^{2+}(aq) + 2\ e^-$
Reduction: $O_2(g) + 4\ H^+(aq) + 4\ e^- \rightarrow 2\ H_2O(\ell)$
Overall: $2\ Fe(s) + O_2(g) + 4\ H^+(aq) \rightarrow 2\ Fe^{2+}(aq) + 2\ H_2O(\ell)$

(b) Anode, oxidation: $Fe(s) \rightarrow Fe^{2+}(aq) + 2\ e^-$
Cathode, reduction: $O_2(g) + 4\ H^+(aq) + 4\ e^- \rightarrow 2\ H_2O(\ell)$

(c) Electrons flow from the negative anode (Fe) to the positive cathode (site of the O_2 half-reaction). Negative ions move through the salt bridge from the cathode compartment in which the O_2 reduction occurs to the anode compartment in which Fe oxidation occurs (and positive ions move in the opposite direction).

19.11 (a) Reduction of Fe^{3+} ions by copper.

Reduction: $Fe^{3+}(aq) + e^- \rightarrow Fe^{2+}(aq)$

Oxidation: $Cu(s) \rightarrow Cu^{2+}(aq) + 2\ e^-$

Overall: $2\ Fe^{3+}(aq) + Cu(s) \rightarrow 2\ Fe^{2+}(aq) + Cu^{2+}(aq)$

(b) Reduction of Fe^{3+} ions by lead

Reduction: $Fe^{3+}(aq) + e^- \rightarrow Fe^{2+}(aq)$

Oxidation: $Pb(s) + SO_4^{2-}(aq) \rightarrow PbSO_4(s) + 2\ e^-$

Overall: $Pb(s) + SO_4^{2-}(aq) + 2\ Fe^{3+}(aq) \rightarrow PbSO_4(s) + 2\ Fe^{2+}(aq)$

19.13 $Cu(s)|Cu^{2+}(aq)\|Cl^-(aq)|Cl_2(g)|Pt$

19.15 (a) All are primary batteries, not rechargeable.
(b) Dry cells and alkaline batteries have Zn anodes and are primary batteries. Ni-Cd batteries have a cadmium anode and are rechargeable.
(c) Dry cells have an acidic environment, whereas the environment is alkaline for alkaline and Ni-Cd cells.

19.17 (a) $E°_{cell} = -1.298$ V; not product-favored
(b) $E°_{cell} = -0.51$ V; not product-favored
(c) $E°_{cell} = -1.023$ V; not product-favored
(d) $E°_{cell} = +0.028$ V; product-favored

19.19 (a) $Sn^{2+}(aq) + 2\ Ag(s) \rightarrow Sn(s) + 2\ Ag^+(aq)$

$E°_{cell} = -0.94$ V; not product-favored

(b) $3\ Sn^{4+}(aq) + 2\ Al(s) \rightarrow 3\ Sn^{2+}(aq) + 2\ Al^{3+}(aq)$

$E°_{cell} = +1.81$ V; product-favored

(c) $2\ ClO_3^-(aq) + 10\ Ce^{3+}(aq) + 12\ H^+(aq) \rightarrow Cl_2(aq) + 10\ Ce^{4+}(aq) + 6\ H_2O(\ell)$

$E°_{cell} = -0.14$ V; not product-favored

(d) $3\ Cu(s) + 2\ NO_3^-(aq) + 8\ H^+(aq) \rightarrow 3\ Cu^{2+}(aq) + 2\ NO(g) + 4\ H_2O(\ell)$

$E°_{cell} = +0.62$ V; product-favored

19.21 (a) Al
(b) Zn and Al
(c) $Fe^{2+}(aq) + Sn(s) \rightarrow Fe(s) + Sn^{2+}(aq)$; reactant-favored at equilibrium
(d) $Zn^{2+}(aq) + Sn(s) \rightarrow Zn(s) + Sn^{2+}(aq)$; reactant-favored at equilibrium

19.23 Best reducing agent, Cr(s) (Use Appendix M.)

19.25 Ag^+

19.27 See Example 19.6
(a) F_2, most readily reduced
(b) F_2 and Cl_2

19.29 $E°_{cell} = +0.3923$ V. When $[Zn(OH)_4^{2-}] = [OH^-] = 0.025$ M and $P(H_2) = 1.0$ bar, $E_{cell} = 0.345$ V.

19.31 $E°_{cell} = +1.563$ V and $E_{cell} = +1.58$ V

19.33 $E°_{cell} = +1.563$ V. When $E_{cell} = 1.48$ V, $n = 2$, and $[Zn^{2+}] = 1.0$ M, the concentration of $Ag^+ = 0.040$ M.

19.35 (a) $\Delta_r G° = -29.0$ kJ; $K = 1 \times 10^5$
(b) $\Delta_r G° = +89$ kJ; $K = 3 \times 10^{-16}$

19.37 $E°_{cell}$ for $AgBr(s) \rightarrow Ag^+(aq) + Br^-(aq)$ is -0.7281.
$K_{sp} = 4.9 \times 10^{-13}$

19.39 $K_{formation} = 2 \times 10^{25}$

19.41 See Figure 19.19. Electrons from the battery or other source enter the cathode where they are transferred to Na^+ ions, reducing the ions to Na metal. Chloride ions move toward the positively charged anode where an electron is transferred from each Cl^- ion, and Cl_2 gas is formed.

19.43 O_2 from the oxidation of water is more likely than F_2. See Example 19.11.

19.45 See Example 19.11.
(a) Cathode: $2\ H_2O(\ell) + 2\ e^- \rightarrow H_2(g) + 2\ OH^-(aq)$
(b) Anode: $2\ Br^-(aq) \rightarrow Br_2(\ell) + 2\ e^-$

19.47 Mass of Ni = 0.0334 g

19.49 Time = 2300 s or 38 min

19.51 Time = 250 h

19.53 (a) $UO_2^+(aq) + 4\ H^+(aq) + e^- \rightarrow U^{4+}(aq) + 2\ H_2O(\ell)$
(b) $ClO_3^-(aq) + 6\ H^+(aq) + 6\ e^- \rightarrow Cl^-(aq) + 3\ H_2O(\ell)$
(c) $N_2H_4(aq) + 4\ OH^-(aq) \rightarrow N_2(g) + 4\ H_2O(\ell) + 4\ e^-$
(d) $ClO^-(aq) + H_2O(\ell) + 2\ e^- \rightarrow Cl^-(aq) + 2\ OH^-(aq)$

19.55 (a, c) The electrode at the right is a magnesium anode. (Magnesium metal supplies electrons and is oxidized to Mg^{2+} ions.) Electrons pass through the wire to the silver cathode, where Ag^+ ions are reduced to silver metal. Nitrate ions move via the salt bridge from the $AgNO_3$ solution to the $Mg(NO_3)_2$ solution (and Na^+ ions move in the opposite direction). A salt bridge is needed to maintain electrical neutrality in each half-cell and to complete the electrical circuit.
(b) Anode: $Mg(s) \rightarrow Mg^{2+}(aq) + 2\ e^-$
Cathode: $Ag^+(aq) + e^- \rightarrow Ag(s)$
Net reaction: $Mg(s) + 2\ Ag^+(aq) \rightarrow Mg^{2+}(aq) + 2\ Ag(s)$

19.57 (a) For 1.7 V:
Use chromium as the anode to reduce $Ag^+(aq)$ to Ag(s) at the cathode. The cell potential is +1.71 V.
(b) For 0.5 V:
(i) Use copper as the anode to reduce silver ions to silver metal at the cathode. The cell potential is +0.46 V.
(ii) Use silver as the anode to reduce chlorine to chloride ions. The cell potential would be +0.56 V. (In practice, this setup is not likely to work well because the product would be insoluble silver chloride.)

19.59 (a) $Zn^{2+}(aq)$ (c) Zn(s)
(b) $Au^+(aq)$ (d) Au(s)
(e) Yes, Sn(s) will reduce Cu^{2+}.
(f) No, Ag(s) can only reduce $Au^+(aq)$.
(g) Cu^{2+}, Ag^+ and Au^+
(h) $Ag^+(aq)$ can oxidize Cu, Sn, Co, and Zn.

19.61 (a) The cathode is the site of reduction, so the half-reaction must be $2\ H^+(aq) + 2\ e^- \rightarrow H_2(g)$. This is the case with the following half-reactions: $Cr^{3+}(aq) \rightarrow Cr(s)$, $Fe^{2+}(aq) \rightarrow Fe(s)$, and $Mg^{2+}(aq) \rightarrow Mg(s)$.
(b) Choosing from the half-cells in part (a), the reaction of Mg(s) and $H^+(aq)$ would produce the most positive potential (2.37 V), and the reaction of H_2 with Cu^{2+} would produce the least positive potential (+0.337 V).

19.63 8.1×10^5 g Al

19.65 (a) $E°_{anode} = -0.268$ V
(b) $K_{sp} = 2 \times 10^{-5}$

19.67 $\Delta_r G° = -409$ kJ

19.69 6700 kWh; 820 kg Na; 1300 kg Cl_2

19.71 Ru^{2+}, $Ru(NO_3)_2$

19.73 9.5×10^6 g Cl_2 per day

19.75 Anode: $2\ H_2O(\ell) \rightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$
Cathode: $Cu^{2+}(aq) + 2\ e^- \rightarrow Cu(s)$

19.77 The rate of the reaction with H_2O is more rapid than the rate of the reaction with NO_3^-.
Products formed at anode: $O_2(g)$ and $H^+(aq)$
Anode half-reaction: $2\ H_2O(\ell) \rightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$

19.79 Under standard conditions, the spontaneous reaction is $Hg^{2+}(aq) + 2\ Fe^{2+}(aq) \rightarrow Hg(\ell) + 2\ Fe^{3+}(aq)$ with $E° = 0.084$ V.
Under the conditions present, $E = -0.244$ V. The reaction is not spontaneous in the same direction as under standard conditions but in the opposite direction: $Hg(\ell) + 2\ Fe^{3+}(aq) \rightarrow Hg^{2+}(aq) + 2\ Fe^{2+}(aq)$. Under these conditions, the anode for the spontaneous reaction is the $Hg(\ell)|Hg^{2+}(aq, 0.020\ M)$ electrode and the measured voltage will be 0.244 V.

19.81 $E° = 0.771$ V. When $[H^+] = 1.0 \times 10^{-7}$ M, $E = 1.185$ V. The reaction is more favorable at a lower $[H^+]$ (higher pH). The reaction is thus less favorable at lower pH.

19.83 (a) See Figure 19.5
In this case, both electrodes are made of silver metal. On one side, the solution contains 1.0×10^{-5} M Ag^+ and on the other the solution contains 1.0 M Ag^+. The cathode is the electrode on the side that has the 1.0 M Ag^+ solution [half-reaction: $Ag^+(aq) + e^- \rightarrow Ag(s)$], and the anode is the electrode on the side that has the 1.0×10^{-5} M Ag^+ solution [half-reaction: $Ag(s) \rightarrow Ag^+(aq) + e^-$]. Connecting the two electrodes is a wire. Electrons flow through the wire from the anode to the cathode. A salt bridge also connects the two compartments.
(b) $E = 0.30$ V

19.85 (a) $K = 3.4 \times 10^{-10}$; reactant-favored at equilibrium
(b) $K = 3.0$; product-favored at equilibrium

19.87 (a) $\Delta_r G° = -3.6 \times 10^2$ kJ/mol-rxn
(b) $\Delta_r G° = -79$ kJ/mol-rxn

19.89 (a) $2[Ag^+(aq) + e^- \rightarrow Ag(s)]$

$$C_6H_5CHO(aq) + H_2O(\ell) \rightarrow C_6H_5CO_2H(aq) + 2\ H^+(aq) + 2\ e^-$$

$$2Ag^+(aq) + C_6H_5CHO(aq) + H_2O(\ell) \rightarrow C_6H_5CO_2H(aq) + 2\ H^+(aq) + 2\ Ag(s)$$

(b) $3[CH_3CH_2OH(aq) + H_2O(\ell) \rightarrow CH_3CO_2H(aq) + 4\ H^+(aq) + 4\ e^-]$

$2[Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ e^- \rightarrow 2\ Cr^{3+}(aq) + 7\ H_2O(\ell)]$

$$3\ CH_3CH_2OH(aq) + 2\ Cr_2O_7^{2-}(aq) + 16\ H^+(aq) \rightarrow 3\ CH_3CO_2H(aq) + 4\ Cr^{3+}(aq) + 11\ H_2O(\ell)$$

19.91 (a) 0.974 kJ/g
(b) 0.60 kJ/g
(c) The silver-zinc battery produces more energy per gram of reactants.

19.93 (a) $2\ NO_3^-(aq) + 3\ Mn^{2+}(aq) + 2\ H_2O(\ell) \rightarrow 2\ NO(g) + 3\ MnO_2(s) + 4\ H^+(aq)$

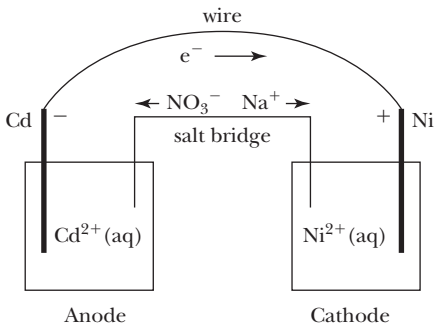
$3\ MnO_2(s) + 4\ H^+(aq) + 2\ NH_4^+(aq) \rightarrow N_2(g) + 3\ Mn^{2+}(aq) + 6\ H_2O(\ell)$

(b) $E°$ for reduction of NO_3^- with Mn^{2+} is -0.27 V.
$E°$ for oxidation of NH_4^+ with MnO_2 is $+1.50$ V.

19.95 (a) $Fe^{2+}(aq) + 2\ e^- \rightarrow Fe(s)$
$2[Fe^{2+}(aq) \rightarrow Fe^{3+}(aq) + e^-]$
$3\ Fe^{2+}(aq) \rightarrow Fe(s) + 2\ Fe^{3+}(aq)$
(b) $E°_{cell} = -1.21$ V; not product-favored
(c) $K = 1 \times 10^{-41}$

19.97 (a) + 4 in CoO_2 and +3 in $LiCoO_2$
(b) Cathode reaction:
$CoO_2(s) + Li^+(Solv) + e^- \rightarrow LiCoO_2(s)$
Anode reaction: $Li(on\ carbon) \rightarrow Li^+(solv) + e^-$
(c) No, because Li, an alkali metal, would react directly with water (giving H_2 and LiOH)

19.99 (a)



(b) Anode: $Cd(s) \rightarrow Cd^{2+}(aq) + 2\ e^-$
Cathode: $Ni^{2+}(aq) + 2\ e^- \rightarrow Ni(s)$
Net: $Cd(s) + Ni^{2+}(aq) \rightarrow Cd^{2+}(aq) + Ni(s)$
(c) The anode is negative and the cathode is positive.
(d) $E°_{cell} = E°_{cathode} - E°_{anode} = (-0.25\ V) - (-0.40\ V) = +0.15$ V
(e) Electrons flow from anode (Cd) to cathode (Ni).
(f) Positive ions move from the anode compartment to the cathode compartment. Anions move in the opposite direction.
(g) $K = 1 \times 10^5$
(h) $E_{cell} = 0.21$ V; yes, the net reaction is still the same.
(i) 480 h

19.101 0.054 g Au

19.103 I^- is the strongest reducing agent of the three halide ions. Iodide ion reduces Cu^{2+} to Cu^+, forming insoluble CuI(s).

$2\ Cu^{2+}(aq) + 4\ I^-(aq) \rightarrow 2\ CuI(s) + I_2(aq)$

19.105 (a) 92 g HF required; 230 g CF_3SO_2F and 9.3 g H_2 isolated
(b) H_2 is produced at the cathode.
(c) 48 kWh

19.107 290 h

19.109 (a) 3.6 mol glucose and 22 mol O_2
(b) 86 mol electrons
(c) 96 amps
(d) 96 watts

Chapter 20

Case Study

What to Do with All of That CO_2? More on Green Chemistry

1. $(9.1 \times 10^9\ g\ C)(1\ mol\ C/12.01\ g\ C)(1\ mol\ CO_2/1\ mol\ C)(44.01\ g\ CO_2/1\ mol\ CO_2) = 3.3 \times 10^{10}\ g\ CO_2$

2. $(1.0 \times 10^6\ g\ CO_2)(1\ mol\ CO_2/44.01\ g\ CO_2)(1\ mol\ (NH_4)_2CO_3/1\ mol\ CO_2)(96.09\ g\ (NH_4)_2CO_3/1\ mol\ (NH_4)_2CO_3) = 2.2 \times 10^6\ g\ (NH_4)_2CO_3$

Section 20-6

1. (d) O_2

Applying Chemical Principles: Alkalinity of Water Supplies

1. (a) At pH = 7.0: from the alpha plot $[CO_3^{2-}]$ is almost zero and $[OH^-] = 1.0 \times 10^{-7}$ M

$[Alk] = 1.00 \times 10^{-3} = [HCO_3^-] + 2\,(0) + (1.00 \times 10^{-7})$

Therefore, $[HCO_3^-] = 1.00 \times 10^{-3}$ M

To find $[H_2CO_3]$ use $K_{a1} = 4.2 \times 10^{-7}$ for

$H_2CO_3(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + H_3O^+(aq)$

which gives $[H_2CO_3] = 2.4 \times 10^{-4}$ M

(b) At pH = 10.0

$[Alk] = 1.00 \times 10^{-3} = [HCO_3^-] + 2\,[CO_3^{2-}] + [OH^-]$

Here $[OH^-] = 1.00 \times 10^{-10}$ M and $[CO_3^{2-}] = K_{a2}[HCO_3^-]/1.0 \times 10^{-10}$

Solving for $[HCO_3^-]$ gives 4.6×10^{-4} M

Now use $K_{a2} = 4.8 \times 10^{-11} = [CO_3^{2-}][H_3O^+]/[HCO_3^-]$

and find $[CO_3^{2-}] = 2.2 \times 10^{-4}$ M

2. Dissolved carbon at pH = 7.0

$[C] = 2.4 \times 10^{-4}$ M + 1.00×10^{-3} M + 0 = 1.24×10^{-4} M

Dissolved carbon at pH = 10.0 (at this pH all CO_2 is in the form of CO_3^{2-} or HCO_3^- ions).

$[C] = 0 + 4.6 \times 10^{-4}$ M + 2.2×10^{-4} M = 6.8×10^{-4} M

Study Questions

20.1 For gases, ppm refers to numbers of particles, and hence to mole fractions. Gas pressure exerted is directly proportional to mole fraction. Thus, 40,000 ppm water vapor would exert a pressure of 40,000/1,000,000 of one atmosphere, or 30.4 mm Hg (0.040 × 760 mm Hg). This would be the case at a little over 29 °C, at 100% humidity.

20.3 (a) 

Electron-pair geometry around N is trigonal planar and around O (between H and N) is tetrahedral.

(b) 5.95×10^{-7} m (or 595 nm)

20.5 0.0115 mg/L of air; 9.7 ppm

20.7 $[HCO_3^-]/[CO_3^-] = 170$

20.9 The amount of NaCl is limited by the amount of sodium present. From a 1.0-L sample of seawater, a maximum of 0.460 mol NaCl could be obtained. The mass of this amount of NaCl is 26.9 g [(0.460 mol/L)(1.00 L)(58.43 g NaCl/1 mol NaCl) = 26.9 g].

20.11 $Ca(OH)_2(s) + Mg^{2+}(aq) \rightarrow Mg(OH)_2(s) + Ca^{2+}(aq)$

$Mg(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Mg^{2+}(aq) + 4\ H_2O(\ell)$

$MgCl_2(\ell) \rightarrow Mg(s) + Cl_2(g)$

20.13 $NH_4^+(aq) + NO_2^-(aq) \rightarrow N_2(g) + 2\ H_2O(\ell)$

$2\ NH_4^+(aq) + 3\ O_2(g) \rightarrow 2\ NO_2^-(aq) + 2\ H_2O(\ell) + 4\ H^+(aq)$

20.15 (a) From methane: $H_2O(g) + CH_4(g) \rightarrow 3\ H_2(g) + CO(g)$

37.7 g of H_2 produced

(b) From petroleum: $H_2O(g) + CH_2(\ell) \rightarrow 2\ H_2(g) + CO\ (g)$

28.7 g H_2 produced

(c) From coal: $H_2O(g) + C(s) \rightarrow H_2(g) + CO(g)$

16.8 g H_2 produced

20.17 70. lb (453.6 g/lb)(33 kJ/g) = 1.0×10^6 kJ

20.19 Assume burning oil produces 43 kJ/g (the value for crude petroleum in Table 20.3)

7.0 gal(3.785 L/gal)(1000 cm^3/L)(0.8 g/cm^3)(43 kJ/g) = 0.9×10^6 kJ. Uncertainty in the numbers is one significant figure. This value is close to the value for the energy obtained by burning from 70 kg of coal (calculated in Question 20.17).

20.21 (a) Isooctane:

$C_8H_{18}(\ell) + 25/2\ O_2(g) \rightarrow 8\ CO_2(g) + 9\ H_2O(\ell)$

$\Delta_r H° = -5461.2$ kJ/mol-rxn (or −47,809 kJ/kg C_8H_{18})

Ethanol:

$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(\ell)$

$\Delta_r H° = -1367.5$ kJ/mol-rxn (or −29,684 kJ/kg C_2H_5OH)

Isooctane releases more energy per kilogram.

(b) Isooctane = 70.0 mol CO_2 and ethanol = 43.4 mol CO_2. Ethanol produces less CO_2 per kilogram.

(c) On the basis of this simplistic comparison, there is not a clear winner. Isooctane releases more energy per kilogram but also releases more CO_2 per kilogram.

20.23 $\Delta_r H°$ for the reaction $CH_3OH(\ell) + 1.5\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$ is −726.8 kJ/mol-rxn.

Energy per liter = -17.9×10^3 kJ/L.

Finally, use the kW-h to kJ conversion factor to obtain the answer.

[$(17.9 \times 10^3$ kJ/L)(1 kW-h/3600 kJ) = 4.96 kW-h/L].

20.25 (a) Area of parking lot = 1.63×10^4 m^2

$(2.6 \times 10^7$ J/$m^2)(1.63 \times 10^4$ $m^2) = 4.2 \times 10^{11}$ J

(b) 1.3×10^7 g C

20.27 Energy per gallon of gas = 1.34×10^5 kJ/gal

Energy to travel 1 mile = 2430 kJ

20.29 (a) The cage is a dodecahedron, so it has 20 vertices, each of which is the O atom of a water molecule (the red spheres in the model are O atoms).

(b) 30 hydrogen bonds. (This estimate is made by assuming there is an H bond on each of the edges.)

(c) A dodecahedron has 12 faces.

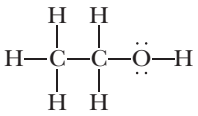
20.31 (a) $C_{13}H_{27}CO_2CH_3(\ell) + 43/2\ O_2(g) \rightarrow 15\ CO_2(g) + 15\ H_2O(g)$

(b) $\Delta_r H° = -8759.1$ kJ/mol-rxn

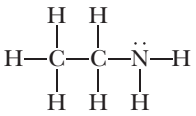
(c) Hexadecane ($\Delta H° = -9951.2$ kJ/mol) provides more energy per mole of fuel than methyl myristate ($\Delta H° = -8759.1$ kJ/mol).

Hexadecane ($\Delta H° = -3.4 \times 10^4$ kJ/L) also provides more energy per liter of fuel than methyl myristate ($\Delta H° = -3.1 \times 10^4$ kJ/L).

20.33 (a)



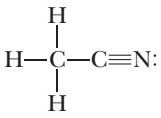
Ethanol



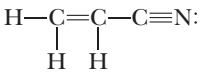
Ethylamine

Both carbon atoms are tetrahedral; oxygen atom is bent.

Both carbon atoms are tetrahedral. Nitrogen atom is pyramidal.



Acetonitrile



Acrylonitrile

CH_3 carbon atom is tetrahedral. Carbon atom of CN group is linear.

CH_2 and CH carbon atoms are trigonal planar. Carbon atom of CN group is linear.

(b) $CH_3CH_2OH + NH_3 \rightarrow CH_3CH_2NH_2 + H_2O$
$CH_3CH_2NH_2 + O_2 \rightarrow CH_3CN + 2\ H_2O$

(c) Reactants (CH_3CH_2OH, NH_3, and O_2) have 2 C, 9 H, 1 N, and 3 O; molar mass = 95. Product (CH_3CN) has 2 C, 3 H, and 1 N; molar mass = 41. Atom economy = (41/95) × 100% = 43%

20.35 Using a C—Cl bond energy of 339 kJ/mol, the wavelength of the required radiation is 3.53×10^{-7} m or 353 nm. This is in the ultraviolet region.

20.37 $NH_4^+(aq) + 2\ H_2O(\ell) \rightarrow NO_2^-(aq) + 8\ H^+(aq) + 6\ e^-$
$NO_2^-(aq) + H_2O(\ell) \rightarrow NO_3^-(aq) + 2\ H^+(aq) + 2\ e^-$

20.39 3.1×10^{13} atoms gold

20.41 (a) Only 92% of the ice is submerged, and the water displaced by ice (the volume of ice under the surface of water) is 23 cm^3 ($0.92 \times 25\ cm^3 = 23\ cm^3$). Thus, the liquid level in the graduated cylinder will be 123 mL.

(b) Melting 25 cm^3 of ice will produce 23 mL of liquid water [25 cm^3 ice (0.92 g H_2O/cm^3 ice) (1.0 cm^3 liquid H_2O/g H_2O) = 23 cm^3 liquid H_2O]. The water level will be 123 mL (the same as in (a); that is, the water level won't rise as the ice melts).

20.43 Non-renewable resources are not replenished when used. Renewable resources are, for the foreseeable future, not depleted when used. Non-renewable: coal, natural gas; renewable: solar, geothermal energy, wind power.

20.45 Troposphere: ozone is toxic and a health hazard, particularly with regard to respiratory problems. Stratosphere: The presence of O_3 is beneficial. Ozone shields the planet from harmful ultraviolet radiation.

20.47 Mercury: from coal burning power plants

Lead: paint residues (before 1970), soil (from the use of tetraethyllead in gasoline), water supplies (from use of lead in pipes and plumbing

Arsenic: some ground water sources, residual from some common chemicals (use in wood treatment, for example)

20.49 (a) Fracking: Positive; greatly increased supply and decreased cost of this energy resource. Negative: contamination of water supplies, excessive water use, release of CH_4 into the atmosphere.

(b) Ethanol in gasoline: Positive: this is a renewable resource. Negative: serious questions about energy balance (energy required to produce ethanol versus energy generated with its use.) Diverts foodstuff from human consumption.

(c) Cars powered by electricity and natural gas: Positive: energy efficiency, zero or low air pollution. Negative: high relative costs even with government subsidies, lack of energy distribution network (electrical distribution stations, natural gas).

20.51 The main pollutant is SO_2, arising from the burning of coal. Some SO_3 in the atmosphere arises from oxidation of SO_2, and this combines with water to give H_2SO_4, a primary component of acid rain. Removing SO_2 is best done at the source, by extracting it from the flue gases of coal burning plants. This can be done by passing the gases from of coal oxidation through a scrubber containing a $CaCO_3$ slurry.

Chapter 21

Case Studies

Hard Water

1. For Mg^{2+}: (50. mg)(1 mmol Mg^{2+}/24.31 mg) (1 mmol CaO/mmol Mg^{2+})(56.08 mg CaO/ 1 mmol CaO) = 120 mg CaO

For Ca^{2+}: (150 mg)(1 mmol Ca^{2+}/40.08 mg) (1 mmol CaO/mmol Ca^{2+})(56.08 mg CaO/ 1 mmol CaO) = 210 mg CaO

Total CaO = 120 mg + 210 mg = 330 mg (two significant figures)

We get 2 mol $CaCO_3$ per mole Ca^{2+} and 1 mol each of $CaCO_3$ and $MgCO_3$ per mole Mg^{2+}

$CaCO_3$ from Ca^{2+} reaction: (0.15 g Ca^{2+}) (1 mol/40.08 g Ca^{2+})(2 mol $CaCO_3$/1 mol Ca^{2+}) (100.1 g $CaCO_3$/1 mol $CaCO_3$) = 0.75 g

$CaCO_3$ from Mg^{2+} reaction: (0.050 g Mg^{2+}) (1 mol/24.31 g Mg^{2+})(1 mol $CaCO_3$/1 mol Mg^{2+}) (100.1 g $CaCO_3$/1 mol $CaCO_3$) = 0.21 g

$MgCO_3$ from Mg^{2+} reaction: (0.050 g Mg^{2+}) (1 mol/24.31 g Mg^{2+})(1 mol $MgCO_3$/1 mol Mg^{2+}) (84.31 g $MgCO_3$/1 mol $MgCO_3$) = 0.17 g

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Total mass of solids = 0.75 g + 0.21 g + 0.17 g = 1.1 g (two significant figures)

2. $CaCO_3(s) + 2\ CH_3CO_2H(aq) \rightarrow Ca(CH_3CO_2)_2(aq) + H_2O(\ell) + CO_2(g)$

This is a gas-forming reaction.

Lead, Beethoven, and a Mystery Solved

1. 50 ppb is 50 g in 1×10^9 g of blood. Assume the density of blood is 1.0 g/mL. In 1.0×10^3 mL (i.e., 1.0 L) of blood, there will be 50×10^{-6} g of Pb. From this:

$(50 \times 10^{-6}\ g)\ (1\ mol\ Pb/207.2\ g\ Pb)$
$(6.022 \times 10^{23}\ atoms\ Pb/mol\ Pb) = 1.5 \times 10^{17}\ atoms\ Pb$

2. (750 mL wine)(1.0 g wine/mL wine)
(2000 g Pb/1,000,000 g wine) = 1.5 g Pb

A Healthy Saltwater Aquarium and the Nitrogen Cycle

1. $2\ NH_4^+(aq) + 4\ OH^-(aq) + 3\ O_2(aq) \rightarrow 2\ NO_2^-(aq) + 6\ H_2O(\ell)$

2. Reduction half-reaction:
$2\ NO_3^-(aq) + 6\ H_2O(\ell) + 10\ e^- \rightarrow N_2(g) + 12\ OH^-(aq)$

Oxidation half-reaction:
$CH_3OH(aq) + 6\ OH^-(aq) \rightarrow CO_2(aq) + 5\ H_2O(\ell) + 6\ e^-$

Net: $6\ NO_3^-(aq) + 5\ CH_3OH \rightarrow 3\ N_2(g) + 5\ CO_2(aq) + 6\ OH^-(aq) + 7\ H_2O(\ell)$

3. HCO_3^- is the predominant species. Recall that when acid and base concentrations are equal, pH = pK_a. If H_2CO_3 and HCO_3^- are present in equal concentrations, the pH would be about 6.4. If HCO_3^- and CO_3^{2-} are present in equal concentrations, the pH would be 10.3. For the pH to be about 8 (in a salt water aquarium), $[HCO_3^-]$ would have to be higher than either of the other carbonate species.

4. Concentration of N in mg/L = $[(1.7 \times 10^4\ kg\ NO_3^-)(10^6\ mg\ NO_3^-/kg\ NO_3^-)(14.0\ mg\ N/62.0\ mg\ NO_3^-)]/(2.2 \times 10^7\ L) = 1.7 \times 10^2$ mg/L

Concentration of NO_3^- in ppm (mg/L) = $(1.7 \times 10^4\ kg)(10^6\ mg/kg)/(2.2 \times 10^7\ L) = 770$ mg/L

Concentration of NO_3^- in mol/L = $[(1.7 \times 10^4\ kg)(10^3\ g/kg)(1\ mol/62.0\ g)]/(2.2 \times 10^7\ L) = 0.012$ mol/L

Check Your Understanding

21.1 (a) $2\ Na(s) + Br_2(\ell) \rightarrow 2\ NaBr(s)$
(b) $Ca(s) + Se(s) \rightarrow CaSe(s)$
(c) $2\ Pb(s) + O_2(g) \rightarrow 2\ PbO(s)$

Lead(II) oxide, a red compound commonly called *litharge*, is the most widely used inorganic lead compound. Maroon-colored lead(IV) oxide is the product of lead oxidation in lead-acid storage batteries. Other oxides such as Pb_3O_4 also exist.

(d) $2\ Al(s) + 3\ Cl_2(g) \rightarrow 2\ AlCl_3(s)$

21.2 (a) H_2Te
(b) Na_3AsO_4
(c) $SeCl_6$
(d) $HBrO_4$

21.3 (a) NH_4^+ (ammonium ion)
(b) O_2^{2-} (peroxide ion)
(c) N_2H_4 (hydrazine)
(d) NF_3 (nitrogen trifluoride)

21.4 (a) In Na_2Cl, chlorine would have the unlikely charge of 2− (to balance the two positive charges of the two Na^+ ions).
(b) This compound would require either the calcium ion to have the formula Ca^+ or the acetate ion to have the formula $CH_3CO_2^{2-}$. In all of its compounds, calcium occurs as the Ca^{2+} ion. The acetate ion, formed from acetic acid by loss of H^+, has a 1− charge.
(c) In Mg_2O, the magnesium ions would need to have the incorrect charge of 1+ to balance charge of the O^{2-} ion or else the oxygen would need to have the incorrect charge of 4− to balance the charge of the two Mg^{2+} ions. Neither of these possibilities is acceptable.

Review & Check

Section 21-2

1. (d) Ca_2O_3

2. (d) tetraphosphorus decaoxide

3. (b) +3

4. (d) +5

Section 21-3

1. (a) neon

2. (c) the high temperature reaction of methane and water

Section 21-4

1. (c) has a high melting point (>400 °C)

2. (a) Li^+

3. (c) two Na^+ ions and one O_2^{2-} ion

Section 21-5

1. (c) gypsum, $CaSO_4 \cdot 2\ H_2O$

2. (c) converting slaked lime, $Ca(OH)_2$, to lime

Section 21-6

1. (c) third

2. (d) dissolve in acid and in base

Section 21-7

1. (c) SiO_2

2. (c) +4

Section 21-8

1. (c) between 2 and 3

2. (b) Aqueous solutions of ammonia are acidic.

3. (c) +3

Section 21-9

1. (c) +3

2. (d) All electrons in O_2 are paired.

Section 21-10

1. (b) Cl_2

2. (c) F_2 is prepared industrially by electrolysis of aqueous NaF.

Section 21-11

1. (c) XeF_3^+

2. (e) octahedral

Applying Chemical Principles: van Arkel Triangles and Bonding

1. (a) CuZn is metallic.
(b) GaAs and BP are semiconductors. As and B are metalloids; Ga and P are not. In both compounds, only one element is a metalloid.
(c) Mg_3N_2 and $SrBr_2$ are ionic. Both are composed of a metal combined with a nonmetal.
(d) Covalent bonding
(e) SBr_2 and C_3N_4 are covalent. Both elements in the compounds are nonmetallic.

Study Questions

21.1 $4\ Li(s) + O_2(g) \rightarrow 2\ Li_2O(s)$

$Li_2O(s) + H_2O(\ell) \rightarrow 2\ LiOH(aq)$

$2\ Ca(s) + O_2(g) \rightarrow 2\ CaO(s)$

$CaO(s) + H_2O(\ell) \rightarrow Ca(OH)_2(s)$

21.3 These are the elements of Group 3A: boron, B; aluminum, Al; gallium, Ga; indium, In; and thallium, Tl.

21.5 $2\ Na(s) + Cl_2(g) \rightarrow 2\ NaCl(s)$

The reaction is exothermic and the product is ionic (see Figure 1.2).

21.7 The product, NaCl, is a colorless solid and is soluble in water. Other alkali metal chlorides have similar properties.

21.9 Calcium will not exist in the Earth's crust because the metal reacts with water.

21.11 Increasing basicity: $CO_2 < SiO_2 < SnO_2$

21.13 (a) $2\ Na(s) + Br_2(\ell) \rightarrow 2\ NaBr(s)$
(b) $2\ Mg(s) + O_2(g) \rightarrow 2\ MgO(s)$
(c) $2\ Al(s) + 3\ F_2(g) \rightarrow 2\ AlF_3(s)$
(d) $C(s) + O_2(g) \rightarrow CO_2(g)$

21.15 $2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(g)$

$H_2(g) + Cl_2(g) \rightarrow 2\ HCl(g)$

$3\ H_2(g) + N_2(g) \rightarrow 2\ NH_3(g)$

21.17 $CH_4(g) + H_2O(g) \rightarrow CO(g) + 3\ H_2(g)$

$\Delta_r H° = +206.2$ kJ; $\Delta_r S° = +214.7$ J/K; $\Delta_r G° = +142.2$ kJ (at 298 K).

21.19 Step 1: $2\ SO_2(g) + 4\ H_2O(\ell) + 2\ I_2(s) \rightarrow 2\ H_2SO_4(\ell) + 4\ HI(g)$

Step 2: $2\ H_2SO_4(\ell) \rightarrow 2\ H_2O(\ell) + 2\ SO_2(g) + O_2(g)$

Step 3: $4\ HI(g) \rightarrow 2\ H_2(g) + 2\ I_2(g)$

Net: $2\ H_2O(\ell) \rightarrow 2\ H_2(g) + O_2(g)$

21.21 $2\ Na(s) + F_2(g) \rightarrow 2\ NaF(s)$

$2\ Na(s) + Cl_2(g) \rightarrow 2\ NaCl(s)$

$2\ Na(s) + Br_2(\ell) \rightarrow 2\ NaBr(s)$

$2\ Na(s) + I_2(s) \rightarrow 2\ NaI(s)$

The alkali metal halides are white, crystalline solids. They have high melting and boiling points, and they are soluble in water.

21.23 (a) $2\ Cl^-(aq) + 2\ H_2O(\ell) \rightarrow Cl_2(g) + H_2(g) + 2\ OH^-(aq)$

(b) If this were the only process used to produce chlorine, the mass of Cl_2 reported for industrial production would be 0.88 times the mass of NaOH produced (2 mol NaCl, 117 g, would yield 2 mol NaOH, 80 g, and 1 mol Cl_2, 70 g). The amounts quoted indicate a Cl_2 to NaOH mass ratio 0.96. Chlorine is presumably also prepared by other routes than this one.

21.25 $2\ Mg(s) + O_2(g) \rightarrow 2\ MgO(s)$

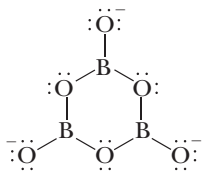
$3\ Mg(s) + N_2(g) \rightarrow Mg_3N_2(s)$

21.27 $CaCO_3$ is used in agriculture to neutralize acidic soil, to prepare CaO for use in mortar, and in steel production.

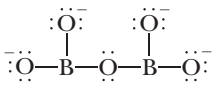
$CaCO_3(s) + H_2O(\ell) + CO_2(g) \rightarrow Ca^{2+}(aq) + 2\ HCO_3^-(aq)$

21.29 1.4×10^6 g SO_2

21.31



$B_3O_6^{3-}$



$B_2O_5^{4-}$

21.33 (a) $2\ B_5H_9(g) + 12\ O_2(g) \rightarrow 5\ B_2O_3(s) + 9\ H_2O(g)$
(b) Enthalpy of combustion of B_5H_9 = −4341.2 kJ/mol. This is more than double the enthalpy of combustion of B_2H_6.
(c) Enthalpy of combustion of $C_2H_6(g)$ [to give $CO_2(g)$ and $H_2O(g)$] = −1428.7 kJ/mol. C_2H_6 produces 47.5 kJ/g, whereas diborane produces much more (73.7 kJ/g).

21.35 $2\ Al(s) + 6\ HCl(aq) \rightarrow 2\ Al^{3+}(aq) + 6\ Cl^-(aq) + 3\ H_2(g)$

$2\ Al(s) + 3\ Cl_2(g) \rightarrow 2\ AlCl_3(s)$

$4\ Al(s) + 3\ O_2(g) \rightarrow 2\ Al_2O_3(s)$

Unless otherwise noted, all art on this page is © Cengage Learning 2015.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

21.37 $2\ Al(s) + 2\ OH^-(aq) + 6\ H_2O(\ell) \rightarrow 2\ Al(OH)_4^-(aq) + 3\ H_2(g)$

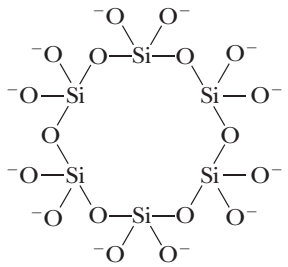
Volume of H_2 obtained from 13.2 g Al = 18.4 L

21.39 $Al_2O_3(s) + 3\ H_2SO_4(aq) \rightarrow Al_2(SO_4)_3(s) + 3\ H_2O(\ell)$

Mass of H_2SO_4 required = 860 g and mass of Al_2O_3 required = 298 g.

21.41 Pyroxenes have as their basic structural unit an extended chain of linked SiO_4 tetrahedra. The ratio of Si to O is 1:3.

21.43 This structure has a six-member ring of Si atoms with O atom bridges. Each Si also has two O atoms attached. The basic unit is SiO_3^{2-}, and the overall charge is −12 in $[(SiO_3)_6]^{-12}$. (Electron lone pairs are omitted in the following structure.)



21.45 Consider the general decomposition reaction:

$$N_xO_y \rightarrow {}^{x}/_{2}\ N_2 + {}^{y}/_{2}\ O_2$$

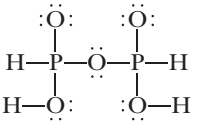
The value of $\Delta G°$ can be obtained for all N_xO_y molecules because $\Delta_r G° = -\Delta_f G°$. These data show that the decomposition reaction is spontaneous for all of the nitrogen oxides. All are unstable with respect to decomposition to the elements.

Compound	$-\Delta_f G°$ (kJ/mol)
NO(g)	−86.58
NO_2	−51.23
N_2O	−104.20
N_2O_4	−97.73

21.47 $\Delta_r H° = -114.4$ kJ/mol-rxn; exothermic $\Delta_r G° = -70.7$ kJ/mol-rxn, product-favored at equilibrium

21.49 (a) $N_2H_4(aq) + O_2(g) \rightarrow N_2(g) + 2\ H_2O(\ell)$
(b) 1.32×10^3 g

21.51 (a) Oxidation number = +3
(b) Diphosphorous acid ($H_4P_2O_5$) should be a diprotic acid (losing the two H atoms attached to O atoms).



21.53 (a) 3.5×10^3 kg SO_2
(b) 4.1×10^3 kg $Ca(OH)_2$

21.55

disulfide ion

21.57 $E°_{cell} = E°_{cathode} - E°_{anode} = +1.44\ V - (+1.51\ V) = -0.07\ V$

The reaction is not product-favored under standard conditions.

21.59 $Cl_2(aq) + 2\ Br^-(aq) \rightarrow 2\ Cl^-(aq) + Br_2(\ell)$

Cl_2 is the oxidizing agent, Br^- is the reducing agent; $E°_{cell} = 0.28$ V.

21.61 The reaction consumes 4.32×10^8 C to produce 8.51×10^4 g F_2.

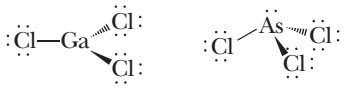
21.63 Xe-F bond dissociation energy = 132 kJ/mol

21.65 0.015 g/L of argon; 2.6×10^3 L for 1.0 mol of argon.

21.67

Element	Appearance	State
Na, Mg, Al	Silvery metal	Solids
Si	Black, shiny metalloid	Solid
P	White, red, and black allotropes; nonmetal	Solid
S	Yellow nonmetal	Solid
Cl	Pale green nonmetal	Gas
Ar	Colorless nonmetal	Gas

21.69 (a) $2\ K(s) + Cl_2(g) \rightarrow 2\ KCl(s)$
$Ca(s) + Cl_2(g) \rightarrow CaCl_2(s)$
$2\ Ga(s) + 3\ Cl_2(g) \rightarrow 2\ GaCl_3(s)$
$Ge(s) + 2\ Cl_2(g) \rightarrow GeCl_4(\ell)$
$2\ As(s) + 3\ Cl_2(g) \rightarrow 2\ AsCl_3(\ell)$
($AsCl_5$ has been prepared but is not stable.)
(b) KCl and $CaCl_2$ are ionic; the other products are covalent.
(c) The electron-pair and molecular geometries of $GaCl_3$ are both trigonal-planar; the electron-pair geometry of $AsCl_3$ is tetrahedral, and its molecular geometry is trigonal-pyramidal.



21.71 (a) $2\ KClO_3(s) \rightarrow 2\ KCl(s) + 3\ O_2(g)$
(b) $2\ H_2S(g) + 3\ O_2(g) \rightarrow 2\ H_2O(g) + 2\ SO_2(g)$
(c) $2\ Na(s) + O_2(g) \rightarrow Na_2O_2(s)$
(d) $P_4(s) + 3\ KOH(aq) + 3\ H_2O(\ell) \rightarrow PH_3(g) + 3\ KH_2PO_2(aq)$
(e) $NH_4NO_3(s) \rightarrow N_2O(g) + 2\ H_2O(g)$
(f) $2\ In(s) + 3\ Br_2(\ell) \rightarrow 2\ InBr_3(s)$
(g) $SnCl_4(\ell) + 2\ H_2O(\ell) \rightarrow SnO_2(s) + 4\ HCl(aq)$

21.73 1.4×10^5 metric tons

21.75 Mg: $\Delta_r G° = +64.9$ kJ
Ca: $\Delta_r G° = +131.40$ kJ
Ba: $\Delta_r G° = +219.4$ kJ
Relative tendency to decompose:
$MgCO_3 > CaCO_3 > BaCO_3$

21.77 (a) $\Delta_f G°$ should be more negative than $(-95.1\ kJ) \times n$.
(b) Ba, Pb, Ti

21.79 O—F bond energy = 190 kJ/mol

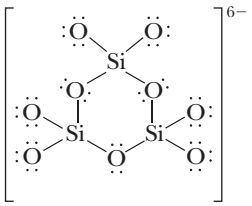
21.81 (a) N_2O_4 is the oxidizing agent (N is reduced from +4 to 0 in N_2), and $H_2NN(CH_3)_2$ is the reducing agent.
(b) 1.3×10^4 kg N_2O_4 is required. Product masses: 5.7×10^3 kg N_2; 4.9×10^3 kg H_2O; 6.0×10^3 kg CO_2.

21.83 $\Delta_r H° = -257.78$ kJ. This reaction is entropy-disfavored, however, with $\Delta_r S° = -963$ J/K because of the decrease in the number of moles of gases. Combining these values gives $\Delta_r G° = +29.19$ kJ, indicating that under standard conditions at 298 K the reaction is not spontaneous. (The reaction has a favorable $\Delta_r G°$ at temperatures less than 268 K, indicating that further research on this system might be worthwhile. Note that at that temperature water is a solid.)

21.85 A = B_2H_6; B = B_4H_{10}; C = B_5H_{11}; D = B_5H_9; E = $B_{10}H_{14}$

21.87 48.6 kiloamps

21.89



The ring is not expected to be planar because a tetrahedral electron-pair geometry is predicted for each atom in the ring.

21.91 $\Delta_r G° = -834.28$ kJ/mol-rxn, therefore the reaction is product-favored at equilibrium at 298 K.

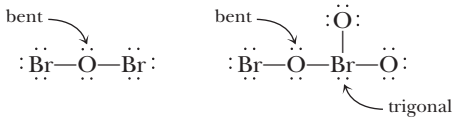
$\Delta_r S° = -149.9$ J/K · mol-rxn at 298 K. Because this is negative, the reaction will be less product-favored at high temperatures.

21.93 (a) $2\ CH_3Cl(g) + Si(s) \rightarrow (CH_3)_2SiCl_2(\ell)$
(b) 0.823 atm
(c) 12.2 g

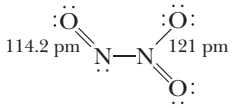
21.95 $5\ N_2H_5^+(aq) + 4\ IO_3^-(aq) \rightarrow 5\ N_2(g) + 2\ I_2(aq) + H^+(aq) + 12\ H_2O(\ell)$

$E°_{net} = 1.43$ V

21.97 (a) Br_2O_3
(b) The structure of Br_2O is reasonably well known. Several possible structures for Br_2O_3 can be imagined, but experiment confirms the structure below.



21.99 (a) The NO bond with a length of 114.2 pm is a double bond. The other two NO bonds (with a length of 121 pm) have a bond order of 1.5 (as there are two resonance structures involving these bonds).



(b) $K = 1.90$; $\Delta_r S° = 141$ J/K · mol-rxn
(c) $\Delta_f H° = 82.9$ kJ/mol

21.101 The flask contains a fixed number of moles of gas at the given pressure and temperature. One could burn the mixture because only the H_2 will combust; the argon is untouched. Cooling the gases from combustion would remove water (the combustion product of H_2) and leave only Ar in the gas phase. Measuring its pressure in a calibrated volume at a known temperature would allow one to calculate the amount of Ar that was in the original mixture.

21.103 Generally, a sodium fire can be extinguished by smothering it with sand. The worst choice is to use water (which reacts violently with sodium to give H_2 gas and NaOH).

21.105 Nitrogen is a relatively unreactive gas, so it will not participate in any reaction typical of hydrogen or oxygen. The most obvious property of H_2 is that it burns, so attempting to burn a small sample of the gas would immediately confirm or deny the presence of H_2. If O_2 is present, it can be detected by allowing it to react as an oxidizing agent. There are many reactions known with low-valent metals, especially transition metal ions in solution, that can be detected by color changes.

21.107 3.5 kW-h

21.109 The reducing ability of the Group 3A metals declines considerably on descending the group, with the largest drop occurring on going from Al to Ga. The reducing ability of gallium and indium are similar, but another large change is observed on going to thallium. In fact, thallium is most stable in the +1 oxidation state. This same tendency for elements to be more stable with lower oxidation numbers is seen in Groups 4A (Ge and Pb) and 5A (Bi).

21.111 (a) $CH_4(g) + 2\ H_2O(\ell) \rightarrow CO_2(g) + 4\ H_2(g)$
$SiH_4(g) + 2\ H_2O(\ell) \rightarrow SiO_2(s) + 4\ H_2(g)$
(b) Reaction of CH_4:
$\Delta_f G° = \Delta_f G°(CO_2) - \Delta_f G°(CH_4) - 2\ \Delta_f G°(H_2O) = +130.7$ kJ
Reaction of SiH_4:
$\Delta_f G° = \Delta_f G°(SiO_2) - \Delta_f G°(SiH_4) - 2\ \Delta_f G°(H_2O) = -439.51$ kJ
The reaction of silane with water is product-favored at equilibrium. This is an important difference between methane and silane.
(c) Electronegativities: C = 2.5, Si = 1.9, H = 2.2. Polarities are in opposite directions: in CH_4, $C^{\delta-}H^{\delta+}$ (H is positive); in SiH_4, $Si^{\delta+}H^{\delta-}$ (H is negative).

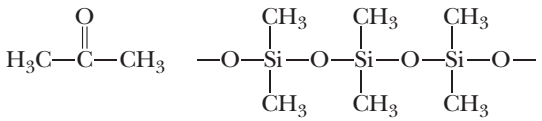
(d) Si prefers to form four single bonds, rather than form a double bond to O, similar to what is seen in acetone. We predict that a molecular species Si_2H_4, analogous to ethane, will not exist; a compound of this formula will be a polymer $—(SiH_2SiH_2)_x—$



Acetone $[(CH_3)_2SiO]_n$ polymer

21.113 (a) $HXeO_4^-$ (Xe oxidation number = +6) is both oxidized (to XeO_6^{4-}, Xe oxidation number = +8) and reduced (to Xe). In addition, O is oxidized to O_2.

(b) One Xe atom in $HXeO_4^-$ loses 2 electrons to give the Xe atom in XeO_6^{4-}. A second Xe atom in $HXeO_4^-$ gains 6 electrons to give Xe. Thus, 2 $HXeO_4^-$ ions require a net of 4 electrons. These electrons can be supplied by the oxidation of 2 O^{2-} ions to give O_2.

Chapter 22

Case Studies

High-Strength Steel

1. Ferrite has a body-centered cubic unit cell.
2. Austenite has a face-centered cubic unit cell of iron atoms with a carbon atom embedded in the body of the cell.
3. The face-centered unit cell of austenite transforms into a body-centered unit cell, but this unit cell is not cubic because it is longer in one dimension than the other two (this is called a *body-centered tetragonal unit cell*). The carbon atoms remain embedded in the lattice.

Cisplatin: Accidental Discovery of a Chemotherapy Agent

$k = 0.693/t_{1/2} = 0.28\ hr^{-1}$

ln (fraction remain) $= -(0.28\ hr^{-1})(24\ hr) = -6.7$

fraction remain $= e^{-6.7} = 0.0013$

Mass remaining = 0.013 mg

The Rare Earths

1. Nd: [Xe] $4f^4\ 6s^2$; Eu: [Xe] $4f^7\ 6s^2$
2. Ce^{3+}: [Xe] $4f^1$
   Nd^{3+}: [Xe] $4f^3$
3. $Fe^{2+}(aq) + [Ce(NO_3)_6]^{2-}(aq) \rightarrow Fe^{3+}(aq) + Ce^{3+}(aq) + 6\ NO_3^-(aq)$

   C = [0.181 g Fe(1 mol Fe/55.85 g Fe)(1 mol [Ce]/mol Fe)]/0.03133 L = 0.103 M
4. $2\ CeO_2(s) + CO(g) \rightarrow Ce_2O_3(s) + CO_2(g)$

   $2\ Ce_2O_3(s) + O_2(g) \rightarrow 4\ CeO_2(s)$

Check Your Understanding

22.1 (a) $Co(NH_3)_3Cl_3$

(b) $Fe(H_2NCH_2CH_2NH_2)_2Br_2 = Fe(en)_2Br_2$

22.2 (a) (i) $K_3[Co(NO_2)_6]$: a complex of cobalt(III) with a coordination number of 6

(ii) $Mn(NH_3)_4Cl_2$: a complex of manganese(II) with a coordination number of 6

(b) $NH_4[Co(EDTA)]$: a complex of cobalt(III) with a coordination number of 6

22.3 (a) hexaaquanickel(II) sulfate

(b) dicyanobis(ethylenediamine)chromium(III) chloride

(c) potassium amminetrichloroplatinate(II)

(d) potassium dichlorocuprate(I)

22.4 (a) Geometric isomers are possible (with the NH_3 ligands in *cis* and *trans* positions).

(b) Only a single structure is possible.

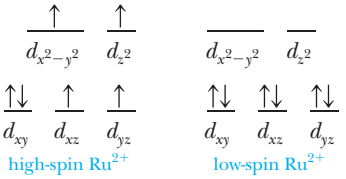
(c) Only a single structure is possible.

(d) This compound is chiral; there are two optical isomers.

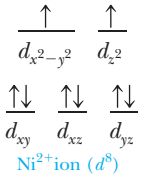
(e) Only a single structure is possible.

(f) Two structural isomers are possible based on coordination of the NO_2^- ligand through oxygen or nitrogen.

22.5 (a) $[Ru(H_2O)_6]^{2+}$: an octahedral complex of ruthenium(II) (d^6). A low-spin complex has no unpaired electrons and is diamagnetic. A high-spin complex has four unpaired electrons and is paramagnetic.



(b) $[Ni(NH_3)_6]^{2+}$: an octahedral complex of nickel(II) (d^8). Only one electron configuration is possible; it has two unpaired electrons and is paramagnetic.



22.6 1. A wavelength of 500 nm corresponds to green light being absorbed. The complex ion will appear magenta.

2. The complex appears yellow because blue light is being absorbed. The high energy of blue light indicates that Δ_o is large and the complex is therefore low spin.

22.27 (a) 6
(b) Octahedral
(c) +2
(d) Four unpaired electrons (high spin)
(e) Paramagnetic

22.29 With four ligands, complexes of the d^8 Ni^{2+} ion can be either tetrahedral or square-planar. The CN^- ligand is at one end of the spectrochemical series and leads to a large ligand field splitting, whereas Cl^- is at the opposite end and often leads to complexes with small orbital splitting. With ligands such as CN^- the complex will be square-planar (and for a d^8 ion it will be diamagnetic). With a weak field ligand (Cl^-) the complex will be tetrahedral and, for the d^8 ion, two electrons will be unpaired, giving a paramagnetic complex.

22.31 The light absorbed is in the green region of the spectrum (page 888). Therefore, the light transmitted—which is the color of the solution—is magenta.

22.33 Determine the magnetic properties of the complex. Square-planar Ni^{2+} (d^8) complexes are diamagnetic, whereas tetrahedral complexes are paramagnetic.

22.35 Fe^{2+} has a d^6 configuration. Low-spin octahedral complexes are diamagnetic, whereas high-spin octahedral complexes of this ion have four unpaired electrons and are paramagnetic.

22.37 Square-planar complexes most often arise from d^8 transition metal ions. Therefore, it is likely that $[Ni(CN)_4]^{2-}$ (Ni^{2+}) and $[Pt(CN)_4]^{2-}$ (Pt^{2+}) are square planar. (See also Study Question 22.29.)

22.39 Two geometric isomers are possible.

22.41 Absorbing at 425 nm means the complex is absorbing light in the blue-violet end of the spectrum. Therefore, red and green light are transmitted, and the complex appears yellow (see Figure 22.27).

22.43 (a) Mn^{2+}; (b) 6; (c) octahedral; (d) 5; (e) paramagnetic; (f) *cis* and *trans* isomers exist.

22.45 Name: tetraamminedichlorocobalt(III) chloride

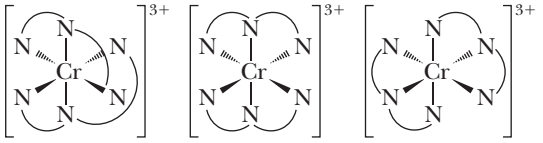
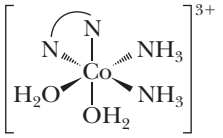
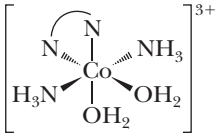
cis chlorides



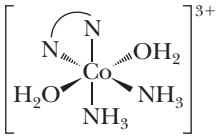
22.51



H_2O and NH_3 *cis*, chiral

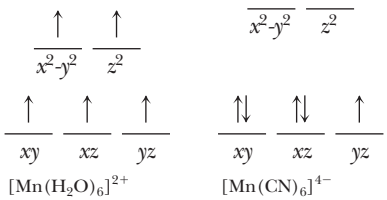


H_2O *cis* and NH_3 *trans*, not chiral



H_2O *trans* and NH_3 *cis*, not chiral

22.53 In $[Mn(H_2O)_6]^{2+}$ and $[Mn(CN)_6]^{4-}$, Mn has an oxidation number of +2 (Mn is a d^5 ion).



$[Mn(H_2O)_6]^{2+}$ paramagnetic, 5 unpaired e^-

$[Mn(CN)_6]^{4-}$ paramagnetic, 1 unpaired e^-

This shows that Δ_o for CN^- is greater than for H_2O.

22.55 (a) Ammonium tetrachlorocuprate(II)
(b) $[Cr(H_2O)_4Cl_2]Cl$
(c) $[Co(H_2O)(NH_2CH_2CH_2NH_2)_2(SCN)](NO_3)_2$

22.57 (a) The light absorbed is in the orange region of the spectrum (page 888). Therefore, the light transmitted (the color of the solution) is blue or cyan.
(b) Using the cobalt(III) complexes in Table 22.3 as a guide, we might place CO_3^{2-} between F^- and the oxalato ion, $C_2O_4^{2-}$.
(c) Δ_o is small, so the complex should be high spin and paramagnetic.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

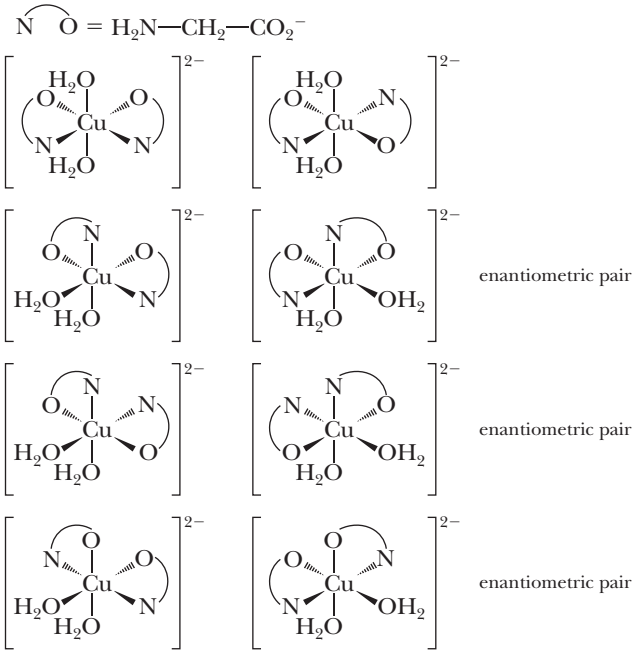
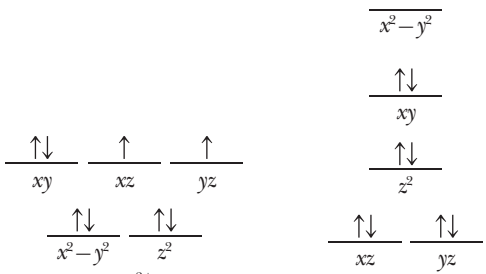
22.59



22.61 (a) In complexes such as $M(PR_3)_2Cl_2$ the metal is Ni^{2+} or Pd^{2+}, both of which are d^8 metal ions. If an Ni^{2+} complex is paramagnetic it must be tetrahedral, whereas the Pd^{2+} must be square planar. (A d^8 metal complex cannot be diamagnetic if it has a tetrahedral structure.)



(b) A tetrahedral Ni^{2+} complex cannot have isomers, whereas a square-planar complex of the type $M(PR_3)_2Cl_2$ can have *cis* and *trans* isomers (see page 878.)

22.63 (a) Ce [Xe] $4f^1\ 5d^1\ 6s^2$
Ce^{3+} [Xe] $4f^1$
Ce^{4+} [Xe] diamagnetic

(b) Ce^{3+} is paramagnetic with 1 unpaired electron. Ce^{4+} is diamagnetic.

(c) A unit cell of CeO_2 consists of Ce^{4+} ions as a face-centered cube (4 Ce^{4+} ions) with O^{2-} ions in all of the tetrahedral holes (8 O^{2-} ions).

22.65 A, dark violet isomer: $[Co(NH_3)_5Br]SO_4$

B, violet-red isomer: $[Co(NH_3)_5(SO_4)]Br$

$$[Co(NH_3)_5Br]SO_4(aq) + BaCl_2(aq) \rightarrow [Co(NH_3)_5Br]Cl_2(aq) + BaSO_4(s)$$

22.67 (a) There is 5.41×10^{-4} mol of $UO_2(NO_3)_2$, and this provides 5.41×10^{-4} mol of U^{n+} ions on reduction by Zn. The 5.41×10^{-4} mol U^{n+} requires 2.16×10^{-4} mol MnO_4^- to reach the equivalence point. This is a ratio of 5 mol of U^{n+} ions to 2 mol MnO_4^- ions. The 2 mol MnO_4^- ions require 10 mol of e^- (to go to Mn^{2+} ions), so 5 mol of U^{n+} ions provide 10 mol e^- (on going to 5 UO_2^{2+} ions, with a uranium oxidation number of +6). This means the U^{n+} ion must be U^{4+}.

(b) $Zn(s) \rightarrow Zn^{2+}(aq) + 2\ e^-$

$$UO_2^{2+}(aq) + 4\ H^+(aq) + 2\ e^- \rightarrow U^{4+}(aq) + 2\ H_2O(\ell)$$

$$UO_2^{2+}(aq) + 4\ H^+(aq) + Zn(s) \rightarrow U^{4+}(aq) + 2\ H_2O(\ell) + Zn^{2+}(aq)$$

(c) $$5[U^{4+}(aq) + 2\ H_2O(\ell) \rightarrow UO_2^{2+}(aq) + 4\ H^+(aq) + 2\ e^-]$$

$$2[MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)]$$

$$5\ U^{4+}(aq) + 2\ MnO_4^-(aq) + 2\ H_2O(\ell) \rightarrow 5\ UO_2^{2+}(aq) + 4\ H^+(aq) + 2\ Mn^{2+}(aq)$$

22.69

Ion	$K_{formation}$ (ammine complexes)
Co^{2+}	1.3×10^5
Ni^{2+}	5.5×10^8
Cu^{2+}	2.1×10^{13}
Zn^{2+}	2.9×10^9

The data for these hexaammine complexes do, indeed, verify the Irving-Williams series. In the book *Chemistry of the Elements* (N. N. Greenwood and A. Earnshaw: 2nd edition, p. 908, Oxford, England, Butterworth-Heinemann, 1997), it is stated: "the stabilities of corresponding complexes of the bivalent ions of the first transition series, irrespective of the particular ligand involved, usually vary in the Irving-Williams order, . . . , which is the reverse of the order for the cation radii. These observations are consistent with the view that, at least for metals in oxidation states +2 and +3, the coordinate bond is largely electrostatic. This was a major factor in the acceptance of the crystal field theory."

22.71 (a) Define length of the side of the cube as x, then the length of the diagonal across the cube is $x\sqrt{3}$. This is set equal to:
$2\ r_{Ti} + 2\ r_{Ni}$, i.e., $x\sqrt{3} = 2\ r_{Ti} + 2\ r_{Ni} = 540$ pm;
$x = 312$ pm ($a = b = c = 3.12 \times 10^{-8}$ cm)

(b) Calculated density:

Mass of one unit cell is the mass of one Ti and one Ni atom = (47.87 g/mol)(1 mol/6.022×10^{23} atoms Ti) + (58.69 g/mol)(1 mol/6.022×10^{23} atoms Ti) = 1.77×10^{-22} g

Volume of the unit cell is $x^3 = (3.12 \times 10^{-8}\ cm)^3 = 3.04 \times 10^{-23}\ cm^3$

Calculated density = 1.77×10^{-22} g/$3.04 \times 10^{-23}\ cm^3 = 5.82\ g/cm^3$

The agreement is not very good, probably because atoms don't pack together as tightly as is assumed.

(c) As free atoms, both Ti and Ni are paramagnetic.

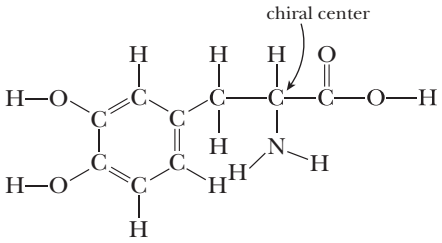
Chapter 23

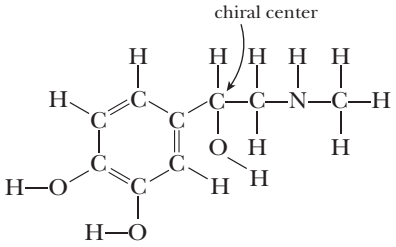
Case Studies

An Awakening with L-DOPA

1. L-DOPA is chiral. Its chiral center is indicated in the following structural formula.



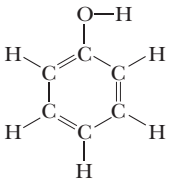
2. Dopamine is not chiral. Epinephrine is chiral. Its chiral center is indicated in the following structural formula.



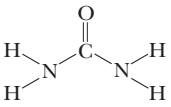
3. 5.0 g L-DOPA (1 mol L-DOPA/197.2 g L-DOPA) = 0.025 mol L-DOPA

Green Adhesives

1. Structural formulas:



phenol



urea

formaldehyde

2. The electron-pair and molecular geometries are both trigonal-planar. The C—H σ bonds are each formed by the overlap of an sp^2 hybrid orbital on the C atom with the 1*s* orbital of the H atom. The σ bond between the C and O is formed by the overlap of an sp^2 hybrid orbital on the C with an sp^2 hybrid orbital on the O. The π bond between the C and O is formed by the overlap of a 2*p* orbital on C with a 2*p* orbital on O.

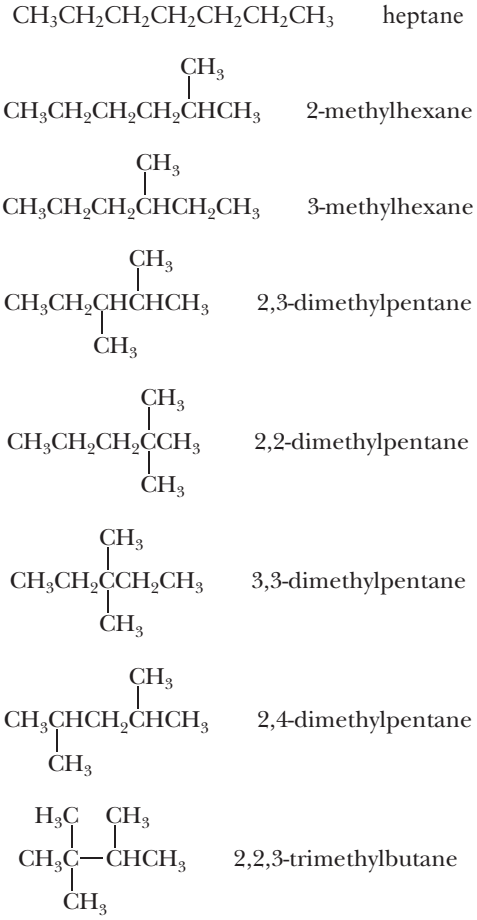
3. Similarity: Both nylon-6,6 and proteins are polyamides.

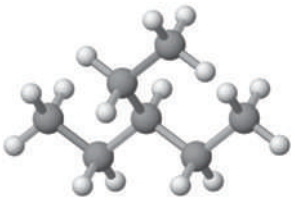
Differences:

1. In proteins there is one direction for the amide linkage: CONH. In nylon-6,6 two orientations are present: CONH and NHCO.
2. In proteins there is only one C between the amide linkages. In nylon-6,6 there are four or six carbons between amide linkages.
3. Proteins have numerous R groups that can be attached to the carbon in between the amide groups, whereas nylon-6,6 has only hydrogen atoms attached to the carbons in between the amide groups.
4. Proteins are chiral, whereas nylon-6,6 is not.

Check Your Understanding

23.1 (a) Isomers of C_7H_{16}





A model of 3-ethylpentane

(b) Two isomers, 3-methylhexane and 2,3-dimethylpentane, are chiral.

23.2 The names accompany the structures in the "Check Your Understanding" answer in Example 23.1.

23.3 Isomers of C_6H_{12} in which the longest chain has six C atoms:

Names (in order, top to bottom): 1-hexene, *cis*-2-hexene, *trans*-2-hexene, *cis*-3-hexene, *trans*-3-hexene. None of these isomers is chiral.

23.4 (a)  bromoethane

(b)  2,3-dibromobutane

23.5 1,4-diaminobenzene

23.6 $CH_3CH_2CH_2CH_2OH$ 1-butanol

 2-butanol

 2-methyl-1-propanol

 2-methyl-2-propanol

23.7 (a) $CH_3CH_2CH_2OH$: 1-propanol, has an alcohol (—OH) group

CH_3CO_2H: ethanoic acid (acetic acid), has a carboxylic acid ($—CO_2H$) group

$CH_3CH_2NH_2$: ethylamine, has an amino ($—NH_2$) group

(b) 1-propyl ethanoate (propyl acetate)

(c) Oxidation of this primary alcohol first gives propanal, CH_3CH_2CHO. Further oxidation gives propanoic acid, $CH_3CH_2CO_2H$.

(d) *N*-ethylacetamide, $CH_3CONHCH_2CH_3$

(e) The amine is protonated by hydrochloric acid, forming ethylammonium chloride, $[CH_3CH_2NH_3]Cl$.

23.8 Kevlar is a condensation polymer, prepared by the reaction of terephthalic acid and 1,4-diaminobenzene.

$$n\ H_2NC_6H_4NH_2 + n\ HO_2CC_6H_4CO_2H \rightarrow \text{—(}HNC_6H_4NHCOC_6H_4CO\text{)—}_n + 2n\ H_2O$$

Review & Check

Section 23-1

1. (c) b and c

2. (a) a and b

3. (c) 2

Section 23-2

1. (c) 2,5-dimethylheptane

2. (c) The compound is an isomer of hexane, is not chiral, and is named 2,2-dimethylbutane.

3. (i) (c) only 3
(ii) (c) 1 and 2

4. (a) 
5. (c) 3

Section 23-3

1. (d) more than 4

2. (a) 2-propanol

3. (a) sp^3

4. (d) NaOH

Section 23-4

1. (d) 1 aldehyde and 2 ketones

2. (b) 2-butanone

3. (d) 120°, sp^2 hybridized

4. (c) ethyl ethanoate

Section 23-5

1. (c) 
Applying Chemical Principles: Bisphenol A (BPA)

1. Reactants: 15 C, 18 H, 3 O, molar mass = 246;
Products: 15 C, 16 H, 2 O, molar mass = 228.

Atom economy = (228/246) × 100% = 92.7%

3. (15 lb)(1 kg/2.2 lb)(13 μg/kg) = 89 μg, more than 50 g recommended.

5. Volume of base needed = (0.300 g BPA)
(1 mol BPA/228 g BPA)(2 mol NaOH/1 mol BPA)
(1.00 L/0.050 mol NaOH) = 0.0526 L (or 52.6 mL)

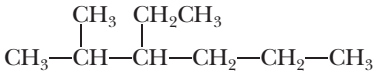
Study Questions

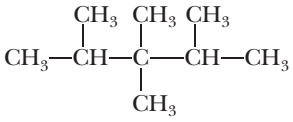
23.1 Heptane

23.3 C_5H_{12} and $C_{14}H_{30}$ are alkanes.

23.5 3-Ethyl-2-methylhexane



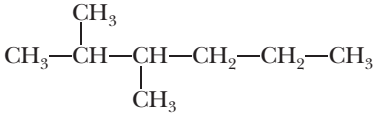
2,3,3,4-Tetramethylpentane



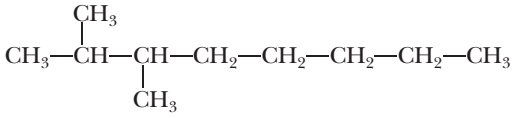
Other possibilities include 2,2,3,4-tetramethylpentane, 3-ethyl-2,2-dimethylpentane, 3-ethyl-2,3-dimethylpentane, and 3-ethyl-2,4-dimethylpentane.

23.7 2,3-Dimethylbutane

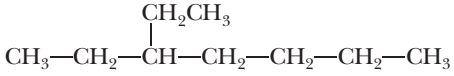
23.9 (a) 2,3-Dimethylhexane



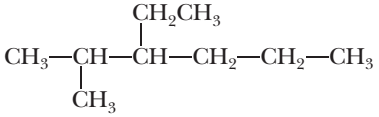
(b) 2,3-Dimethyloctane



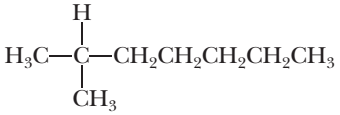
(c) 3-Ethylheptane



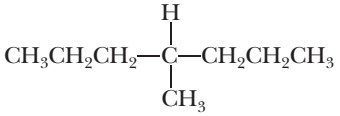
(d) 3-Ethyl-2-methylhexane



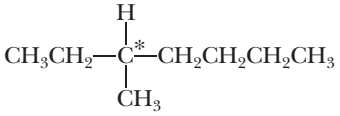
23.11



2-methylheptane

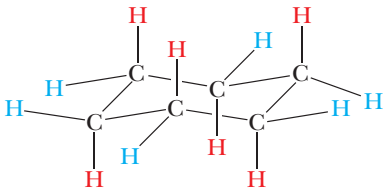


4-methylheptane



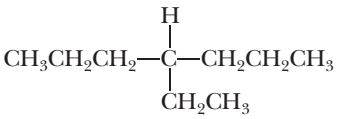
3-methylheptane. The C atom with an asterisk is chiral.

23.13 Chair form of cyclohexane:

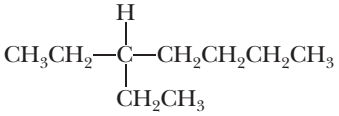


Axial hydrogens are shown in red; equatorial hydrogens are shown in blue.

23.15



4-ethylheptane. The compound is not chiral.

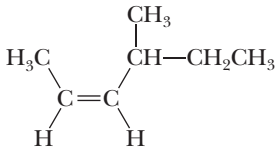


3-ethylheptane. Not chiral.

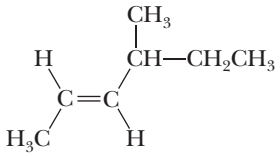
23.17 C_4H_{10}, butane: a low-molar-mass fuel gas at room temperature and pressure. Slightly soluble in water.

$C_{12}H_{26}$, dodecane: a colorless liquid at room temperature. Expected to be insoluble in water but quite soluble in nonpolar solvents.

23.19

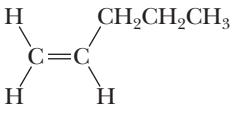


cis-4-methyl-2-hexene

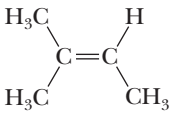


trans-4-methyl-2-hexene

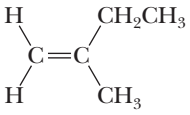
23.21 (a)



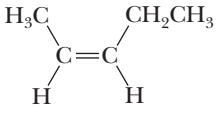
1-pentene



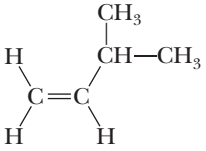
2-methyl-2-butene



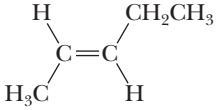
2-methyl-1-butene



cis-2-pentene

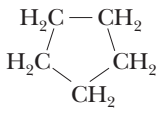


3-methyl-1-butene



trans-2-pentene

(b)



cyclopentane

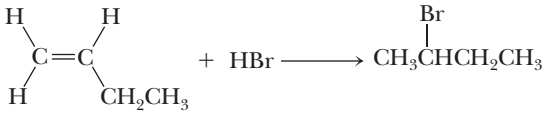
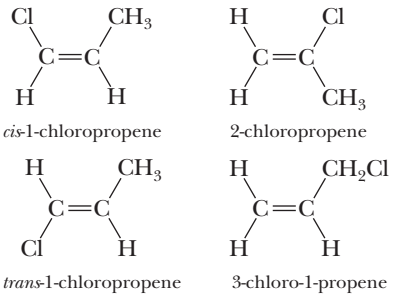
23.23 (a) 1,2-Dibromopropane, $CH_3CHBrCH_2Br$
(b) Pentane, C_5H_{12}

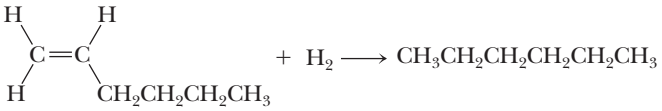
23.25 The three alkenes are 1-butene, *cis*-2-butene, and *trans*-2-butene. The reaction with 1-butene is shown below:



23.27 Four isomers are possible.

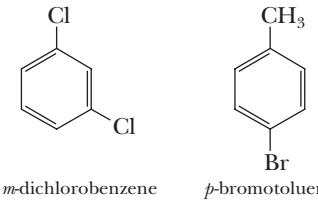


23.29

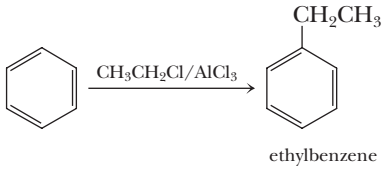


Hydrogenation is often carried out in the presence of a metal catalyst (Pt, Pd, Rh). Hydrogenation is used in the food industry to convert liquid oils to solids and to make them less susceptible to spoilage.

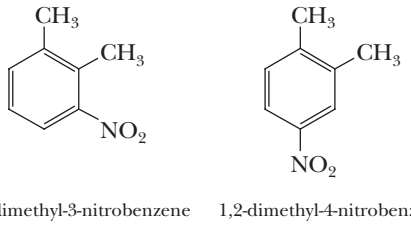
23.31



23.33

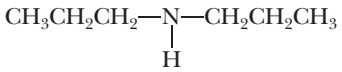


23.35

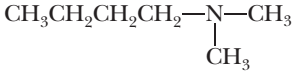


23.37 (a) 1-Propanol, primary
(b) 1-Butanol, primary
(c) 2-Methyl-2-propanol, tertiary
(d) 2-Methyl-2-butanol, tertiary

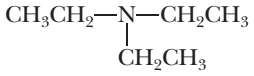
23.39 (a) Ethylamine, $CH_3CH_2NH_2$
(b) Dipropylamine, $(CH_3CH_2CH_2)_2NH$



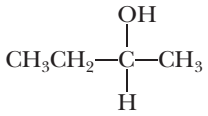
(c) Butyldimethylamine



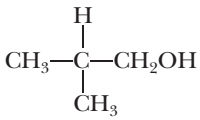
(d) Triethylamine



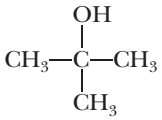
23.41 (a) 1-Butanol, $CH_3CH_2CH_2CH_2OH$
(b) 2-Butanol



(c) 2-Methyl-1-propanol

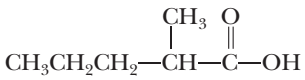


(d) 2-Methyl-2-propanol

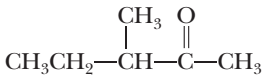


23.43 (a) $C_6H_5NH_2(\ell) + HCl(aq) \rightarrow (C_6H_5NH_3)Cl(aq)$
(b) $(CH_3)_3N(aq) + H_2SO_4(aq) \rightarrow [(CH_3)_3NH]HSO_4(aq)$

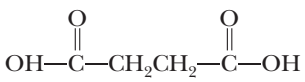
23.45 (a)



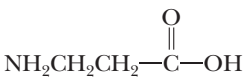
(b)



(c)



(d)



23.47

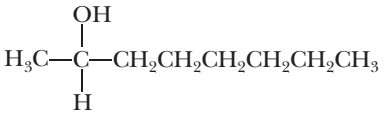
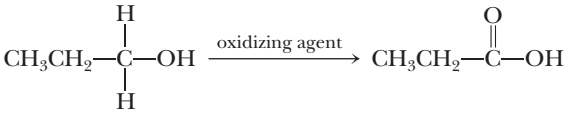
23.49 (a) Acid, 3-methylpentanoic acid
(b) Ester, methyl propanoate
(c) Ester, butyl acetate (or butyl ethanoate)
(d) Acid, *p*-bromobenzoic acid

23.51 (a) Pentanoic acid

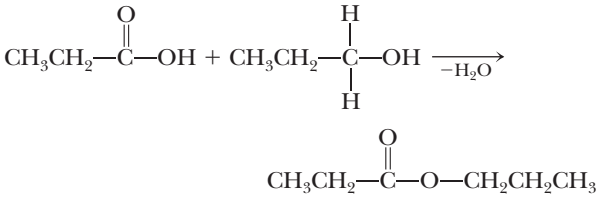
(b) 2-Octanol



23.53 Step 1: Oxidize 1-propanol to propanoic acid.



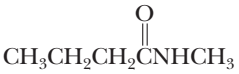
Step 2: Combine propanoic acid and 1-propanol.



23.55 Sodium acetate, $NaCH_3CO_2$, and 1-butanol, $CH_3CH_2CH_2CH_2OH$

23.57 (a) Trigonal-planar
(b) 120°
(c) The molecule is chiral. There are four different groups around the carbon atom marked 2.
(d) The acidic H atom is the H attached to the CO_2H (carboxyl) group.

23.59

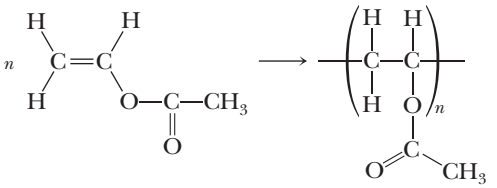


This compound is an amide.

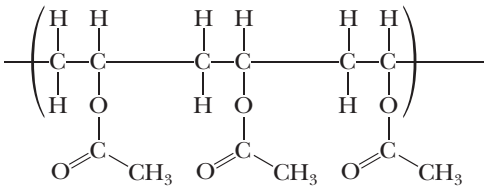
$$CH_3CH_2CH_2CO_2H + CH_3NH_2 \rightarrow CH_3CH_2CH_2CONHCH_3 + H_2O$$

23.61 (a) Alcohol (b) amide (c) acid (d) ester

23.63 (a) Prepare polyvinyl acetate (PVA) from vinylacetate.

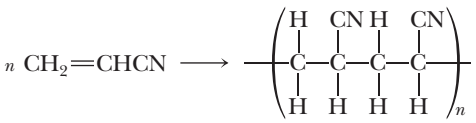


(b) Three units of PVA:

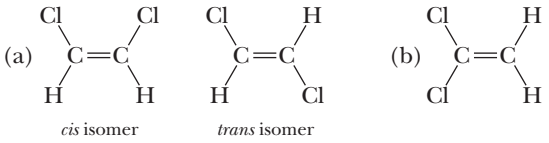


(c) Hydrolysis of polyvinyl acetate will yield polyvinyl alcohol.

23.65 Polyacrylonitrile from acrylonitrile.

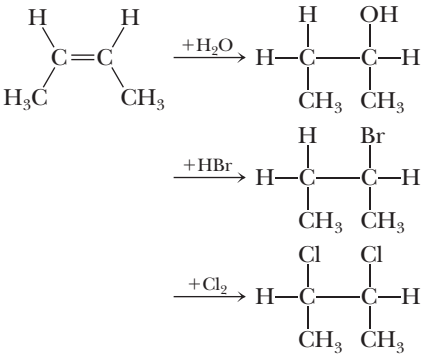


23.67

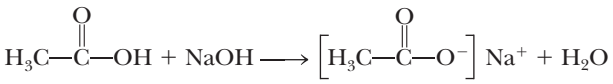


23.69 Five isomers: 1-hexene, *cis*- and *trans*-2-hexene, and *cis*- and *trans*-3-hexene.

23.71



23.73 (a)



(b)

23.75

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b)

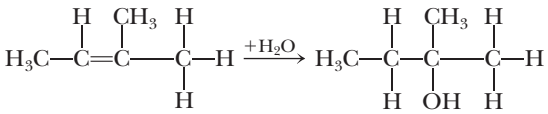
2-methyl-2-butanol

(c)

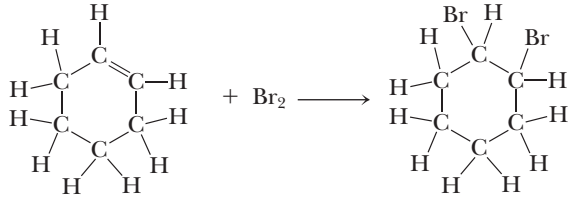


The product is the same for parts (b) and (c).

23.93 (a) The only structural difference between theobromine and caffeine occurs on the N in the six-member ring that is between the two C=O groups. In theobromine, there is an H atom attached to this N. In caffeine, there is a CH_3 group attached.
(b) 5.00 g sample (2.16 g theobromine/100 g sample) = 0.108 g theobromine

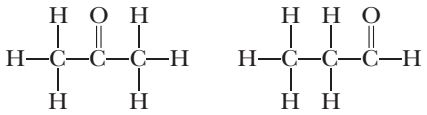
23.95 Compound (b), acetaldehyde, and (c), ethanol, produce acetic acid when oxidized.

23.97 Cyclohexene, a cyclic alkene, will add Br_2 readily (to give $C_6H_{10}Br_2$).



Benzene, however, needs much more stringent conditions to react with bromine; then Br_2 will substitute for H atoms on benzene and not add to the ring.

23.99 (a) The compound is either propanone, a ketone, or propanal, an aldehyde.

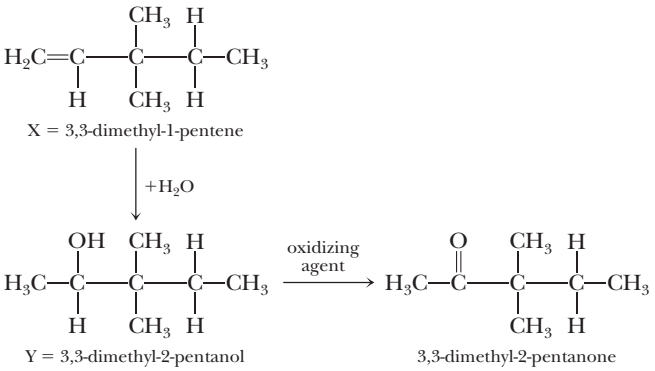


propanone (a ketone) propanal (an aldehyde)

(b) The ketone will not undergo oxidation, but the aldehyde will be oxidized to the acid, $CH_3CH_2CO_2H$. Thus, the unknown is likely propanal.
(c) Propanoic acid

23.101 2-Propanol will react with an oxidizing agent such as $KMnO_4$ (to give the ketone), whereas methyl ethyl ether ($CH_3OC_2H_5$) will not react. In addition, the alcohol should be more soluble in water than the ether.

23.103

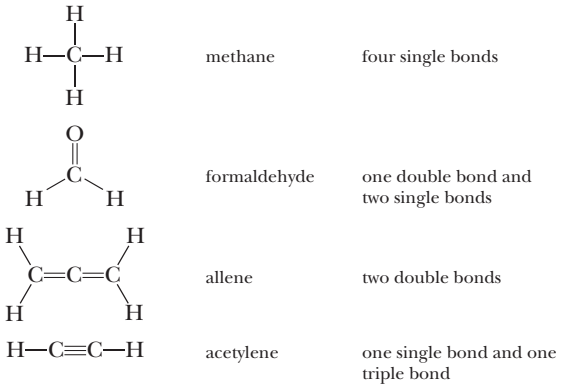


X = 3,3-dimethyl-1-pentene

Y = 3,3-dimethyl-2-pentanol 3,3-dimethyl-2-pentanone

23.105 The ^{18}O label will be found in dimethyl terephthalate.

23.107



methane — four single bonds

formaldehyde — one double bond and two single bonds

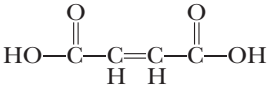
allene — two double bonds

acetylene — one single bond and one triple bond

23.109 (a) Cross-linking makes the material very rigid and inflexible.
(b) The OH groups give the polymer a high affinity for water.
(c) Hydrogen bonding allows the chains to form coils and sheets with high tensile strength.

23.111 (a) Ethane enthalpy of combustion = −47.51 kJ/g
Ethanol enthalpy of combustion = −26.82 kJ/g
(b) The enthalpy change for the combustion of ethanol is less negative than for ethane, so partially oxidizing ethane to form ethanol decreases the amount of energy per gram available from the combustion of the substance.

23.113 (a) Empirical formula, CHO
(b) Molecular formula, $C_4H_4O_4$
(c)



(d) All four C atoms are sp^2 hybridized.
(e) 120°

1. (b) ethanol

2. (c) polar heads pointing to both the extracellular fluid and the intracellular fluid

Section 24-5

1. (c) exothermic and product-favored at equilibrium

2. (d) NADH

Applying Chemical Principles: Polymerase Chain Reaction

1. $2^{20} = 1{,}048{,}576$

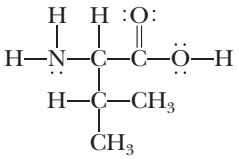
3. (a) Cytosine and guanine bind with three hydrogen bonds per base pair, whereas adenine and thymine (uracil) bind with only two. Sequences with a high number of cytosines and guanines will thus bind more strongly.

(b) This sequence could fold over and base pair to itself instead of to the target strand.

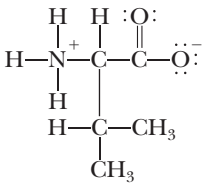
(c) Using a large excess of primers ensures that the target strands will bind to the primers instead of having the complementary target strands bind to each other.

Study Questions

24.1 (a)



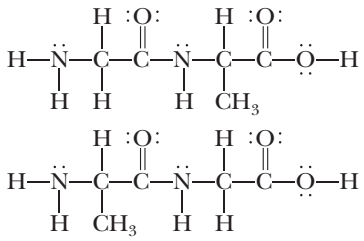
(b)



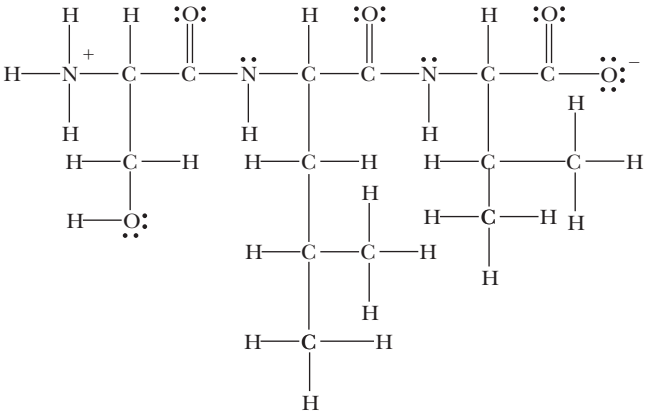
(c) The zwitterionic form is the predominant form at physiological pH.

24.3 Polar: serine, lysine, aspartic acid
Nonpolar: alanine, leucine, phenylalanine

24.5



24.7



24.9 (a) primary
(b) quaternary
(c) tertiary

(b) (2803 kJ/mol)(1 mol/6.022 × 10^{23} molecules) (1000 J/1 kJ) = 4.655 × 10^{-18} J/molecule

(c) λ = 650 nm(1 m/10^9 nm) = 6.5 × 10^{-7} m

$E = hc/\lambda = (6.626 \times 10^{-34}\ J \cdot s)(3.00 \times 10^{8}\ m \cdot s^{-1})/(6.5 \times 10^{-7}\ m) = 3.1 \times 10^{-19}$ J

(d) The energy per photon is less than the amount required per molecule of glucose, therefore multiple photons must be absorbed.

24.31 There are four nucleotide bases, and each codon is three nucleotides long, so there are $4^3 = 64$ codons possible. Some amino acids have more than one codon.

24.33 oxidation: $C_6H_{12}O_6$
reduction: O_2

24.35 A graph of y = 1/Rate and x = 1/[S] yields a straight line with the equation $y = 1.5x + 9200$. The y-intercept corresponds to $1/Rate_{max}$, so $Rate_{max} = 1/9200 = 1.1 \times 10^{-4}$ mol/L · min.

24.37 glycine

24.39 The sequences differ in the positions of attachments of the phosphate to deoxyribose on adjacent units. Consider the A-T attachments. In ATGC, the phosphate links the 3′ position on A to the 5′ position on T. In CGTA, the phosphate links the 5′ position on A to the 3′ position on T.

24.41 (a) In transcription, a strand of RNA complementary to the segment of DNA is constructed.
(b) In translation, an amino acid sequence is constructed based on the information in an mRNA sequence.

Chapter 25

Case Study

Technetium-99m and Medical Imaging

1. $^{99}_{42}Mo \rightarrow {}^{99}_{43}Tc + {}^{0}_{-1}\beta$

2. Oxidation number = 7
Tc^{7+} electron configuration = [Kr]
Diamagnetic

3. Amount $NaTcO_4$ = (1.0 μg)(1 g/10^6 μg)(1 mol/184.9 g) = 5.4 × 10^{-9} mol
Mass Tc = (5.4 × 10^{-9} mol $NaTcO_4$)(1 mol Tc/mol $NaTcO_4$)(97.9 g Tc/mol) = 5.3 × 10^{-7} g Tc

4. 24 hours is 4 half-lives for ^{99m}Tc. Thus, mass remaining is 1/16th of 1.0 μg, or 0.063 μg.

5. Beta particle

6. The attractive forces binding an anion to the column are related to the anion charge. The anion MoO_4^{2-} has a higher charge than TcO_4^-.

Check Your Understanding

25.1 (a) Emission of six α particles leads to a decrease of 24 in the mass number and a decrease of 12 in the atomic number. Emission of four β particles increases the atomic number by 4 but doesn't affect the mass. The final product of this process has a mass number of 232 − 24 = 208 and an atomic number of 90 − 12 + 4 = 82, identifying it as $^{208}_{82}Pb$.

(b) Step 1: $^{232}_{90}Th \rightarrow {}^{228}_{88}Ra + {}^{4}_{2}\alpha$
Step 2: $^{228}_{88}Ra \rightarrow {}^{228}_{89}Ac + {}^{0}_{-1}\beta$
Step 3: $^{228}_{89}Ac \rightarrow {}^{228}_{90}Th + {}^{0}_{-1}\beta$

25.2 (a) $^{0}_{+1}\beta$ (b) $^{41}_{19}K$ (c) $^{0}_{-1}\beta$ (d) $^{22}_{10}Ne$

25.3 (a) $^{32}_{14}Si \rightarrow {}^{32}_{15}P + {}^{0}_{-1}\beta$
(b) $^{45}_{22}Ti \rightarrow {}^{45}_{21}Sc + {}^{0}_{+1}\beta$ or $^{45}_{22}Ti + {}^{0}_{-1}e \rightarrow {}^{45}_{21}Sc$
(c) $^{239}_{94}Pu \rightarrow \alpha + {}^{235}_{92}U$
(d) $^{42}_{19}K \rightarrow {}^{42}_{20}Ca + {}^{0}_{-1}\beta$

25.4 Δm = 0.03435 g/mol
$\Delta E = (3.435 \times 10^{-5}\ kg/mol)(2.998 \times 10^{8}\ m/s)^2 = 3.087 \times 10^{12}$ J/mol (= 3.087 × 10^9 kJ/mol)
$E_b = 5.146 \times 10^{8}$ kJ/mol nucleons

25.5 (a) 49.2 years is exactly four half-lives; quantity remaining = 1.5 mg$(1/2)^4$ = 0.094 mg
(b) Three half-lives, 36.9 years
(c) 1% is between six half-lives, 73.8 years (1/64 remains), and seven half-lives, 86.1 years (1/128 remains). [Using the integrated first-order rate equation with $[R]/[R]_0 = 0.010$ and $k = (\ln 2)/t_{1/2} = 0.0564\ y^{-1}$, the amount of time is calculated to be 81.7 years.]

25.6 (a) $\ln([A]/[A_o]) = -kt$
$\ln([3.18 \times 10^3]/[3.35 \times 10^3]) = -k(2.00\ d)$
$k = 0.0260\ d^{-1}$
$t_{1/2} = 0.693/k = 0.693/(0.0260\ d^{-1}) = 26.7$ d

(b) $k = 0.693/t_{1/2} = 0.693/200\ y = 3.47 \times 10^{-3}\ y^{-1}$
$\ln([A]/[A_o]) = -kt$
$\ln([3.00 \times 10^3]/[6.50 \times 10^{12}]) = -(3.47 \times 10^{-3}\ y^{-1})t$
$\ln(4.62 \times 10^{-10}) = -(3.47 \times 10^{-3}\ y^{-1})t$
t = 6190 y

25.7 $\ln([A]/[A_o]) = -kt$
$\ln([9.32]/[13.4]) = -(1.21 \times 10^{-4}\ y^{-1})t$
$t = 3.00 \times 10^3$ y
This compares quite well with the estimated date.

25.8 $^{98}_{42}Mo + {}^{1}_{0}n \rightarrow {}^{99}_{42}Mo + \gamma$
$^{99}_{42}Mo \rightarrow {}^{99}_{43}Tc + {}^{0}_{-1}\beta$

25.9 $4.17 \times 10^{-5}(0.0100\ g\ Pb^{2+}) = 4.17 \times 10^{-7}\ g\ Pb^{2+}$
Solubility = [4.17×10^{-7} g Pb^{2+} (1 mol Pb^{2+}/207.2 g Pb)(1 mol $PbCrO_4$/1 mol Pb^{2+})]/0.01000 L = 2.01×10^{-7} mol $PbCrO_4$/L

Review & Check

Section 25-2

1. (a) alpha radiation

2. (b) 7 α and 4 β

3. (c) $^{90}_{38}\text{Sr} \rightarrow {}^{90}_{39}\text{Y} + \beta$

Section 25-3

1. (c) $^{56}_{26}\text{Fe}$

Section 25-4

1. (a) 20%

2. (d) 1/32

Section 25-5

1. (c) electrons

Section 25-6

1. (a) $^{93}_{37}\text{Rb}$

Applying Chemical Principles: The Age of Meteorites

1. $^{87}_{37}\text{Rb} \rightarrow {}^{87}_{38}\text{Sr} + {}^{0}_{-1}\beta$

3. $k = 1.42 \times 10^{-11}\ \text{y}^{-1}$

5. Age of meteorite $= 2.80 \times 10^{9}$ y

Study Questions

25.1 Each answer is in the format: person(s); experiment; significance.

(a) Becquerel; potassium uranyl sulfate caused an image to appear on a photographic plate; this opened up a new area of study.

(b) Marie and Pierre Curie; separated these elements from pitchblende; discovery of new elements based on radioactivity.

(c) Rutherford; bombarded ^{14}N with α particles and found protons and ^{17}O among products; human-caused transmutation of one element into another.

(d) Fermi; absorption of a neutron by a nucleus with subsequent release of a γ ray; production of more nuclei and the use of this process to produce many of the radioisotopes used in medicine.

(e) Hahn and Strassman, experiment explained by Meitner; bombarded a sample of uranium with neutrons and detected barium in products; nuclear fission is used in atomic bombs and in nuclear energy plants.

25.3 Binding energy per nucleon is determined by first calculating the mass defect for an isotope, converting the mass defect to binding energy (using $E = mc^2$) and then dividing the binding energy by the mass number of the nucleus.

25.5 Nuclear reactions are carried out in a laboratory by hitting a nucleus with a particle. Various particles have been used: α particles, protons, neutrons, and the nuclei of other atoms. In producing transuranium elements, this last method is used; the particles are usually accelerated to high energy in a particle accelerator.

25.7 While an organism lives, the percentage of carbon that is ^{14}C in the organism will equal the percentage in the atmosphere. When the organism dies, it no longer replenishes the ^{14}C. By measuring the activity of ^{14}C in the organism, comparing it to the ambient ^{14}C activity, and using first-order kinetics, it is possible to determine how long ago the organism stopped taking in ^{14}C (died). Limitations: (1) The method assumes that the amount of ^{14}C in the atmosphere has remained constant, whereas it has varied by as much as 10%. (2) ^{14}C dating cannot be used to date an object less than 100 or more than about 40,000 years old. (3) The accuracy of ^{14}C dating is about $\pm$100 years.

25.9 A radioactive decay series occurs when a radioactive isotope decays to form another radioactive isotope. The series continues until a nonradioactive isotope is formed. Uranium ore contains radium and polonium because these elements are formed in the radioactive decay series of uranium.

25.11 (a) $^{56}_{28}\text{Ni}$; (b) $^{1}_{0}\text{n}$; (c) $^{32}_{15}\text{P}$; (d) $^{97}_{43}\text{Tc}$; (e) $^{0}_{-1}\beta$; (f) $^{0}_{1}\text{e}$ (positron)

25.13 (a) $^{0}_{-1}\beta$; (b) $^{87}_{37}\text{Rb}$; (c) $^{4}_{2}\alpha$; (d) $^{226}_{88}\text{Ra}$; (e) $^{0}_{-1}\beta$; (f) $^{24}_{11}\text{Na}$

25.15

$^{235}_{92}\text{U} \rightarrow {}^{231}_{90}\text{Th} + {}^{4}_{2}\alpha$

$^{231}_{90}\text{Th} \rightarrow {}^{231}_{91}\text{Pa} + {}^{0}_{-1}\beta$

$^{231}_{91}\text{Pa} \rightarrow {}^{227}_{89}\text{Ac} + {}^{4}_{2}\alpha$

$^{227}_{89}\text{Ac} \rightarrow {}^{227}_{90}\text{Th} + {}^{0}_{-1}\beta$

$^{227}_{90}\text{Th} \rightarrow {}^{223}_{88}\text{Ra} + {}^{4}_{2}\alpha$

$^{223}_{88}\text{Ra} \rightarrow {}^{219}_{86}\text{Rn} + {}^{4}_{2}\alpha$

$^{219}_{86}\text{Rn} \rightarrow {}^{215}_{84}\text{Po} + {}^{4}_{2}\alpha$

$^{215}_{84}\text{Po} \rightarrow {}^{211}_{82}\text{Pb} + {}^{4}_{2}\alpha$

$^{211}_{82}\text{Pb} \rightarrow {}^{211}_{83}\text{Bi} + {}^{0}_{-1}\beta$

$^{211}_{83}\text{Bi} \rightarrow {}^{211}_{84}\text{Po} + {}^{0}_{-1}\beta$

$^{211}_{84}\text{Po} \rightarrow {}^{207}_{82}\text{Pb} + {}^{4}_{2}\alpha$

25.17 (a) $^{198}_{79}\text{Au} \rightarrow {}^{198}_{80}\text{Hg} + {}^{0}_{-1}\beta$

(b) $^{222}_{86}\text{Rn} \rightarrow {}^{218}_{84}\text{Po} + {}^{4}_{2}\alpha$

(c) $^{137}_{55}\text{Cs} \rightarrow {}^{137}_{56}\text{Ba} + {}^{0}_{-1}\beta$

(d) $^{110}_{49}\text{In} \rightarrow {}^{110}_{48}\text{Cd} + {}^{0}_{1}\text{e}$

25.19 (a) $^{80}_{35}\text{Br}$ has a high neutron/proton ratio of 45/35. Beta decay will allow the ratio to decrease: $^{80}_{35}\text{Br} \rightarrow {}^{80}_{36}\text{Kr} + {}^{0}_{-1}\beta$.

(b) Alpha decay is likely: $^{240}_{98}\text{Cf} \rightarrow {}^{236}_{96}\text{Cm} + {}^{4}_{2}\alpha$

(c) Cobalt-61 has a high *n/p* ratio, so beta decay is likely: $^{61}_{27}\text{Co} \rightarrow {}^{61}_{28}\text{Kr} + {}^{0}_{-1}\beta$

(d) Carbon-11 has only five neutrons, so K-capture or positron emission may occur:

$^{11}_{6}C + {}^{0}_{-1}e \rightarrow {}^{11}_{5}B$

$^{11}_{6}C \rightarrow {}^{11}_{5}B + {}^{0}_{1}e$

25.21 Generally beta decay will occur when the *n/p* ratio is high, whereas positron emission will occur when the *n/p* ratio is low.

(a) Beta decay: $^{20}_{9}F \rightarrow {}^{20}_{10}Ne + {}^{0}_{-1}\beta$

$^{3}_{1}H \rightarrow {}^{3}_{2}He + {}^{0}_{-1}\beta$

(b) Positron emission

$^{22}_{11}Na \rightarrow {}^{22}_{10}Ne + {}^{0}_{1}\beta$

25.23 Binding energy per mole of nucleons for ^{11}B = 6.70×10^{8} kJ

Binding energy per mole of nucleons for ^{10}B = 6.26×10^{8} kJ

25.25 8.256×10^{8} kJ/mol nucleons

25.27 7.700×10^{8} kJ/mol nucleons

25.29 0.781 micrograms

25.31 (a) $^{131}_{53}I \rightarrow {}^{131}_{54}Xe + {}^{0}_{-1}\beta$

(b) 0.075 micrograms

25.33 9.5×10^{-4} mg

25.35 (a) $^{222}_{86}Rn \rightarrow {}^{218}_{84}Po + {}^{4}_{2}\alpha$

(b) Time = 8.87 d

25.37 (a) 15.8 y; (b) 88%

25.39 $^{239}_{94}Pu + {}^{4}_{2}\alpha \rightarrow {}^{240}_{95}Am + {}^{1}_{1}H + 2\ {}^{1}_{0}n$

25.41 $^{48}_{20}Ca + {}^{242}_{94}Pu \rightarrow {}^{287}_{114}Fl + 3\ {}^{1}_{0}n$

25.43 (a) $^{115}_{48}Cd$; (b) $^{7}_{4}Be$; (c) $^{4}_{2}\alpha$; (d) $^{63}_{29}Cu$

25.45 $^{10}_{5}B + {}^{1}_{0}n \rightarrow {}^{7}_{3}Li + {}^{4}_{2}\alpha$

25.47 Time = 4.4×10^{10} y

25.49 If $t_{1/2}$ = 14.28 d, then $k = 4.854 \times 10^{-2}$ d^{-1}. If the original disintegration rate is 3.2×10^{6} dpm, then (from the integrated first order rate equation), the rate after 365 d is 0.065 dpm. The plot will resemble Figure 25.5.

25.51 (a) $^{238}_{92}U + {}^{1}_{0}n \rightarrow {}^{239}_{92}U + \gamma$

(b) $^{239}_{92}U \rightarrow {}^{239}_{93}Np + {}^{0}_{-1}\beta$

(c) $^{239}_{93}Np \rightarrow {}^{239}_{94}Pu + {}^{0}_{-1}\beta$

(d) $^{239}_{94}Pu + {}^{1}_{0}n \rightarrow 2\ {}^{1}_{0}n$ + energy + other nuclei

25.53 (a) Calcium-48. Possible reaction is

$^{248}_{96}Cm + {}^{48}_{20}Ca \rightarrow {}^{296}_{116}Lv$

(b) Three neutrons

25.55 About 2700 years old

25.57 Plot ln(activity) versus time. The slope of the plot is $-k$, the rate constant for decay. Here, $k = 0.0050$ d^{-1}, so $t_{1/2}$ = 140 d.

25.59 Time = 1.9×10^{9} y

25.61 Energy obtained from 1.000 lb (452.6 g) of $^{235}U = 4.1 \times 10^{10}$ kJ

Mass of coal required = 1.6×10^{3} ton (or about 3 million pounds of coal)

25.63 The percentage of tagged fish in the lake is (27/5250)100% = 0.51%. Therefore, 1000 tagged fish is 0.51% of the total or approximately 190,000 fish.

25.65 (a) The mass decreases by 4 units (with an $^{4}_{2}\alpha$ emission) or is unchanged (with a $^{0}_{-1}\beta$ emission), so the only masses possible are 4 units apart.

(b) ^{232}Th series, $m = 4n$; ^{235}U series $m = 4n + 3$

(c) ^{226}Ra and ^{210}Bi, $4n + 2$ series; ^{215}At, $4n + 3$ series; ^{228}Th, $4n$ series

(d) Each series is headed by a long-lived isotope (in the order of 10^{9} years, the age of the Earth). The $4n + 1$ series is missing because there is no long-lived isotope in this series. Over geologic time, all the members of this series have decayed completely.

25.67 (a) ^{231}Pa isotope belongs to the ^{235}U decay series (see Question 25.65b).

(b) $^{235}_{92}U \rightarrow {}^{231}_{90}Th + {}^{4}_{2}\alpha$

$^{231}_{90}Th \rightarrow {}^{231}_{91}Pa + {}^{0}_{-1}\beta$

(c) Pa-231 is present to the extent of 1 part per million. Therefore, 1 million grams of pitchblende need to be used to obtain 1 g of Pa-231.

(d) $^{231}_{91}Pa \rightarrow {}^{227}_{89}Ac + {}^{4}_{2}\alpha$

25.69 Pitchblende contains $^{238}_{92}U$ and $^{235}_{92}U$. Thus, both radium and polonium isotopes must belong to either the $4n + 2$ or $4n + 3$ decay series. Furthermore, the isotopes must have sufficiently long half-lives in order to survive the separation and isolation process. These criteria are satisfied by ^{226}Ra and ^{210}Po.

Index / Glossary

Italicized page numbers indicate pages containing illustrations, and those followed by "t" indicate tables. Glossary terms, printed in boldface, are defined here as well as in the text.

abbreviations, A-9
ABS plastic, 936
absolute temperature scale. *See* Kelvin temperature scale.
absolute zero The lowest possible temperature, equivalent to −273.15 °C, used as the zero point of the Kelvin scale, 25, 376
  zero entropy at, 687
absorbance The negative logarithm of the transmittance, 174
  concentration and, *508*
absorption spectrum A plot of the intensity of light absorbed by a sample as a function of the wavelength of the light, 174, 890
  excited states and, *230*
  of chlorophyll *a* and *b*, *971*
absorptivity, molar, 175
abundance(s), of elements in Earth's crust, 59t
  of isotopes, 49, 51t
acceptor level, in semiconductor, *455*
accuracy The agreement between the measured quantity and the accepted value, 29
  of acid–base indicators, 654
acetaldehyde, 925t
acetaminophen, structure of, 930
acetate ion, buffer solution of, 637t
  reaction with phosphoric acid, 602
acetic acid, 927t
  as weak acid, 105, 592, 594
  as weak electrolyte, 107
  buffer solution of, 637t
  glacial, 627
  hydrogen bonding in, *413*
  ionization of, 632
  orbital hybridization in, 351
  partial charges in, *621*
  production of, 924, 926
  quantitative analysis of, 151
  reaction with ammonia, 604
  reaction with sodium bicarbonate, 602
  reaction with sodium hydroxide, 120, 927
  reaction with water, 117
  structure of, *115*, *899*, 923
  titration with sodium hydroxide, 647–650
acetic anhydride, 149
acetone, 925t
  hydrogenation of, 330
  structure of, 351, 923
acetylacetonate ion, as ligand (acac), 870
N-acetyl-*p*-aminophenol, 930
acetylene, orbital hybridization in, 351
  structure of, 898
N-acetylglucosamine (NAG), 952
N-acetylmuramic acid (NAM), 952
acetylsalicylic acid. *See* aspirin.
acid(s) A substance that, when dissolved in pure water, increases the concentration of hydrogen ions, 114–122. *See also* **Brønsted acid(s), Lewis acid(s)**.
  Arrhenius definition of, 116
  bases and, 584–629. *See also* **acid–base reaction(s)**.
  Brønsted–Lowry definition, 116–119, 586
  carboxylic. *See* carboxylic acid(s).
  common, 115t
  Lewis definition of, 622–627
  pH of, 161–164
  reaction with bases, 119–121
  strengths of, 593, 595t
    direction of reaction and, 601
    in nonaqueous solvents, 627
    logarithmic (pK_a), 597
    molecular structure and, 617–622
    strong. *See* strong acid.
    weak. *See* weak acid.
acid–base adduct, 623
acid–base indicator(s), 653–655
acid–base reaction(s) An exchange reaction between an acid and a base producing a salt and water, 119–121, 132
  conjugate pairs in, 588
  direction of, acid–base strength and, 601
  equivalence point of, 167, 644
  pH after, 612
  titration using, 166–170, 644–655
  types of, 603, 605t
acid ionization constant (K_a) The equilibrium constant for the ionization of an acid in aqueous solution, 593, 595t
  relation to conjugate base ionization constant, 597
  values of, A-20
acid rain, 123, 766, 781, 790
acidic oxide(s) An oxide of a nonmetal that acts as an acid, 122
acidic solution A solution in which the concentration of hydronium ions is greater than the concentration of hydroxide ion, 590
acidosis, 645
acoustic energy The energy of compression and expansion of spaces between molecules, 17
Acrilan, 933t
acrylonitrile-polybutadiene-styrene (ABS) plastic, 936
actinide(s) The series of elements between actinium and rutherfordium in the periodic table, 62, 858
  electron configurations of, 260
activation energy (E_a) The minimum amount of energy that must be absorbed by a system to cause it to react, 531
  bond energies and, 536
  experimental determination, 534
  reduction by catalyst, 536
active site, in enzyme, 951
active transport, through cell membrane, 968
activity (*A*) A measure of the rate of nuclear decay, the number of disintegrations observed in a sample per unit time, 989
activity, thermodynamic, 559
actual yield The measured amount of product obtained from a chemical reaction, 147

acute mountain sickness, 370

addition polymer(s) A synthetic organic polymer formed by directly joining monomer units, 932–936
  production from ethylene derivatives, 934

addition reaction(s), of alkenes and alkynes, 910

adduct, acid–base, 623

adenine, 332
  hydrogen bonding to thymine, 414, 958
  in DNA and RNA, 956, *957*

adenosine 5′-diphosphate (ADP), 706, 969

adenosine 5′-triphosphate (ATP), 963, 969
  structure of, 706

adhesive force A force of attraction between molecules of two different substances, 431

adhesives, chemistry of, 940
  on gecko's toes, 404

adipoyl chloride, 938

adrenaline, 923

adsorption, of gas molecules on solid surface, 398

aerosol, 498t

Agency for Toxic Substances and Disease Registry (ATSDR), *775*

air, argon in, 92
  components of, 388t
  density of, 384
  environmental concerns, 764–771
  fractional distillation of, 843
  noble gases in, 852
  pollution of, 790, 845

air bags, 372, 379

alanine, structure of, *947*

albite, dissolved by rain water, 172

alchemy, 974

alcohol(s) Any of a class of organic compounds characterized by the presence of a hydroxyl group bonded to a saturated carbon atom, 788, 917–922
  common, 918t
  energy content of, 28
  miscibility in water, 920
  naming of, 918, A-17
  oxidation to carbonyl compounds, 924

aldehyde(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to at least one hydrogen atom, 924, 925
  naming of, A-17
  reduction to primary alcohols, 925

aldose, 953

algae, biomass production by, 800
  fatty acids extracted from, 430
  oxygen production by, 766
  phosphates and, 774

alkali metal(s) The metals in Group 1A of the periodic table, 58
  electron configuration of, 256
  ions, enthalpy of hydration, 408
  reaction with halogens, 815
  reaction with oxygen, 815
  reaction with water, 58, 814
  reduction potentials of, 814

alkaline battery, 730

alkaline earth metal(s) The elements in Group 2A of the periodic table, 59, 817–821
  biological uses of, 821
  electron configuration of, 256

alkalinity The ability of a water supply to accept hydronium ions, 799

alkaloid, 584

alkalosis, 645

alkane(s) Any of a class of hydrocarbons in which each carbon atom is bonded to four other atoms, 902–907
  derivatives of, 917t
  general formula of, 902t
  in petroleum, 785
  naming of, 905, A-15
  properties of, 906
  reaction with chlorine, 906
  reaction with oxygen, 906
  standard enthalpies of vaporization of, 424t

Alka-Seltzer®, *130*

alkene(s) Any of a class of hydrocarbons in which there is at least one carbon–carbon double bond, 907–910
  general formula of, 902t
  hydrogenation of, 912
  naming of, A-16

alkyd paint, 798

alkyl group A part of a molecular structure derived by removing a hydrogen atom from an alkane molecule, 905

alkylation, of benzene, 915

alkyne(s) Any of a class of hydrocarbons in which there is at least one carbon–carbon triple bond, 910
  general formula of, 902t
  naming of, A-16

allene, structure of, *899*

allotrope(s) Different forms of the same element that exist in the same physical state under the same conditions of temperature and pressure, 59
  boron, 822
  carbon, 59, *60*, 709
  oxygen, 61, 843. *See also* ozone.
  phosphorus, 60, 834
  sulfur, 61, 843
  tin, 466

alloy(s), aluminum, 823
  atom substitution in, 267
  iron, 866
  magnesium in, 818

Alnico V, 866

alpha-hydroxy acid(s), *615*

alpha particle(s) A helium nucleus ejected from certain radioactive substances, 976
  bombardment with, 993, 994
  predicting emission of, 983

alpha ray(s). *See* **alpha particle(s)**.

alternative energy sources, 784–789

altitude sickness, 370

Altman, Sidney, 962

alum, crystallization of, 483
  in water purification, 772

aluminosilicates, 830
  separation of, 823

aluminum, abundance of, 59, 822
  chemistry of, 826
  electron configuration of, 260
  oxidation of, 143
  production of, 823
  reaction with bromine, 826
  reaction with copper ions, 716
  reaction with sodium hydroxide, 812
  reaction with water, 721
  reduction by sodium, 813
  similarity to beryllium, 822

aluminum bromide, dimerization of, 827

aluminum carbide, reaction with water, 149

aluminum fluoride ion, 827

aluminum hydroxide, amphoterism of, 623, *625*

aluminum oxide, 823
  amphoterism of, 823
  in gemstones, 248

aluminum sulfate, coagulation of colloidal particles by, 499

amalgam, mercury, 741

americium, 995

amethyst, 828

amide(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to an amino group, 924, 929

amide link, 930, 938

amine(s) A derivative of ammonia in which one or more of the hydrogen atoms are replaced by organic groups, 921
  reaction with carboxylic acids, 929
  solubility in water, 921

α-amino acid(s) A compound containing an amine group and a carboxylic acid group, both attached to the same carbon atom, 946
  chirality of, 946
  structure of, 946
  zwitterionic form, 948

amino group A functional group related to ammonia, in which some or all of the hydrogen atoms are replaced by organic groups, 929

ammine, naming ammonia as ligand, 875

ammonia, aqueous, equilibrium constant expression for, 559
as Lewis base, 623, *624*, 626
as ligand, 870, 875
as refrigerant, 768
as weak base, 593, 594
bond angles in, 309, *310*
combustion of, balanced equation for, 101
decomposition of, 516
molecular polarity of, 322
orbital hybridization in, 345
oxidation of, 144, 148
percent composition of, 84
pH of, 162
production of, as equilibrium process, 103
by Haber process, 579
entropy change for, 690
equilibrium constant for, 573
free energy change, 705
spontaneity of, 695
stoichiometry of, 386
reaction with acetic acid, 604
reaction with hydrochloric acid, 604
reaction with hydrogen chloride, 120, 391
reaction with hypochlorous acid, 775
reaction with sodium hypochlorite, 835
reaction with water, 116
relation to amines, 921
titration with hydrochloric acid, 651
waste product of fish metabolism, 838
ammonium carbonate, reaction with carbon dioxide, 794
ammonium chloride, decomposition of, 695
in dry cell battery, 730
ammonium hydrogen carbonate, in purification of carbon dioxide, 794
ammonium ion, 68, 71
in Lewis adduct, 623
ammonium nitrate, decomposition of, 835
dissolution of, 681
enthalpy of solution, 476
ammonium perchlorate, in rocket fuel, 851
amorphous solid(s) A solid that lacks long-range regular structure and displays a melting range instead of a specific melting point, 459
amount, of pure substance, 78. *See also* **mole (mol)**.
amounts table, in solving stoichiometry problems, 140. *See also* ICE table.
ampere (A) The unit of electric current, 757, A-10
Ampère, André Marie, 847
amphibole, 829
amphiphile A molecule that has both polar and nonpolar groups, 797
amphiprotic substance A substance that can behave as either a Brønsted acid or a Brønsted base, 118, 587
amphoteric substance A substance, such as a metal hydroxide, that can behave as either an acid or base, 623, 625t
aluminum oxide, 823
amplitude The maximum height of a wave, as measured from the axis of propagation, *220,* 236
amylopectin starch, 955, *956*
amylose starch, 955, *956*
anaerobic fermentation, 918
analysis, chemical. *See* **chemical analysis**.
spectrophotometric, 175
Anderson, Carl, 980
anesthetic, xenon as, 852
Ångstrom unit (Å), *26,* A-12
angular momentum quantum number, 237
number of nodal surfaces and, 241
anhydrous compound The substance remaining after the water has been removed (usually by heating) from a hydrated compound, 75
aniline, as weak base, 596
reaction with sulfuric acid, 922
structure of, 914
anilinium hydrogen sulfate, 922
anion(s) An ion with a negative electric charge, 67
acid–base properties of, 598
as Brønsted acids and bases, 586, 622
as Lewis bases, 623
naming, 71
noble gas electron configuration in, 263, 278
sizes of, 275
annealing, in steel production, 867
anode The electrode of an electrochemical cell at which oxidation occurs, 723
in corrosion, 863
in electrolysis cell, 752
sacrificial, 758
antacid(s), 177
anthracite, 781
antibonding molecular orbital A molecular orbital in which the energy of the electrons is higher than that of the parent orbital electrons, 355
anticodon, 960
antifreeze, 488
ethylene glycol in, 472
antilogarithms, A-3
antimatter, 980
antimony, abundance of, 834
isotopic abundance of, 51
antineutrino, 981
antisense therapy, 964
apatite(s), 819, 840
apophyllite, *832*
Appian Way, mortar in, 819
approximation, solving quadratic equations by, 569
successive, method of, 569, A-5
aqua, naming water as ligand, 875
aqua regia, 1, 837
aqua sphere. *See* water.
aquarium, nitrogen cycle in, 838
aqueous solution A solution in which the solvent is water, 105–109
balancing redox equations in, 718–722
electrolysis in, 753
equilibrium constant expression for, 559
aquifer, depletion of, 771
aragonite, solubility of, 796
arginine, structure of, *947*
argon, abundance of, 852
discovery of, 92
in atmosphere, 765
isotope ratios, 53
argyria, 131
Arnold, James R., 991
aromatic compound(s) Any of a class of hydrocarbons characterized by the presence of a benzene ring or related structure, 353, 912–915
general formula of, 902t
in petroleum, 785
naming of, A-17
properties of, 915
Arrhenius, Svante, 116
Arrhenius equation A mathematical expression that relates reaction rate to activation energy, collision frequency, and molecular orientation, 533
arsenic, abundance of, 834
poisoning by, 90
water pollution by, 775
arsine, 839
asbestos, 817, 829
ascorbic acid, titration of, 171
asparagine, structure of, *947*
aspartic acid, structure of, 947
Aspdin, Joseph, 831
aspirin, melting point of, *15*
molar mass of, 82
structure of, *23,* 928
synthesis of, 149
astatine, abundance of, 846
Athabasca sands, 783
atmosphere. *See also* air.
carbon-14 isotope in, 990–991
composition of, 388t, 764t
mass of, 765
pressure–temperature profile of, 392
standard, 372. *See also* **standard atmosphere (atm)**.
atom(s) The smallest particle of an element that retains the characteristic chemical properties of that element, 8, 10
Bohr model of, 227–232
composition of, 47
electron configurations of, 254–263. *See also* electron configuration(s).
mass of, 46
quantization of energy in, 227, 235
size of, 47, 267. *See also* atomic radius
structure of, 45, 55, 218–247

atom economy, 331
green chemistry and, 150
atomic bomb, 996
atomic mass The experimentally determined mass of an atom of one isotope, 47–50
atomic mass unit (amu) The unit of a scale of relative atomic masses of the elements; 1 amu = 1/12 of the mass of a carbon atom with six protons and six neutrons, 47, A-13t
equivalent in grams, 47
atomic number (*Z*) The number of protons in the nucleus of an atom of an element, 46
chemical periodicity and, 57
even versus odd, and nuclear stability, 982
in nuclear symbol, 977
atomic orbital(s) The matter wave for an allowed energy state of an electron in an atom, 237
assignment of electrons to, 251–254
energies of, and electron assignments, 251–254
number of electrons in, 251t
order of energies in, 251, 262
orientations of, 241
overlapping of, in valence bond theory, 340
penetration of, 253
quantum numbers of, 237
shapes of, 239–243
atomic radius, bond length and, 326
bond length and, effective nuclear charge and, 269
in transition elements, 862
periodicity, 267–269
determining, 443
atomic theory of matter A theory that describes the structure and behavior of substances in terms of ultimate chemical particles called atoms and molecules, 45
atomic weight The average mass of an atom in a natural sample of the element, 50
atropine, 614
Atwater system, for energy content of foods, 28
Aufbau principle, 251
austenite, unit cell of, 867
autoimmune deficiency syndrome (AIDS), 962–963
autoionization of water Proton transfer between two water molecules to produce a hydronium ion and a hydroxide ion, 589
automobile, electric, *712*
Autumn, Kellar, 404
average reaction rate, 509
Avogadro, Amedeo, 78, 380
Avogadro's hypothesis Equal volumes of gases under the same conditions of temperature and pressure have equal numbers of particles, 379
kinetic-molecular theory and, 395
Avogadro's number The number of particles in one mole of any substance (6.0221415×10^{23}), 78, A-13t
axial position, in cyclohexane structure, 907
in trigonal bipyramidal molecular geometry, 311
azo dye, 366
azomethane, decomposition of, 522, 524
azurite, 22, *656*, 658, *864*

background radiation, 999
bacteria, copper production by, 868
destruction by copper, 856, 857
in drinking water, 772
methane produced by, 769
sulfur-oxidizing, 844
bacteriocide, silver as, 131, 799
baking powder, 842
baking soda, 124, 815
reaction with vinegar, 602
balance, laboratory, *4*
laboratory, precision of, *33*
balanced chemical equation A chemical equation showing the relative amounts of reactants and products, 97–102
enthalpy and, 199
ball-and-stick models, 65, 900
balloon, helium, 810
hot-air, *383*
hydrogen, 810
models of electron pair geometries, 307
weather, 378
Balmer, Johann, 227
Balmer equation, 227
Balmer series, 227, 231
in spectra of stars, 244
balsam, toluene in, 913
band gap, 454
band of stability, nuclear, 983
band theory, of metallic bonding, 452
of semiconductors, 454
bar A unit of pressure; 1 bar = 100 kPa, 372, A-7
barite, 658
barium, abundance of, 817
salts of, in fireworks, 233
barium chloride, as strong electrolyte, 106
reaction with sodium sulfate, 113, 151–152, 670
barium(II) chloride dihydrate, 411
barium nitrate, as strong electrolyte, 107
barium sulfate, as x-ray contrast agent, 659, 821
precipitation of, 113, 669
solubility of, 658
barometer An apparatus used to measure atmospheric pressure, 372
mercury, 372
Bartlett, Neil, 852
base(s) A substance that, when dissolved in pure water, increases the concentration of hydroxide ions, 114–122. *See also* **Brønsted base(s), Lewis base(s)**.
acids and, 584–629. *See also* **acid–base reaction(s)**.
amines as, 921
Arrhenius definition of, 116
Brønsted–Lowry definition, 116–119, 586
common, 115t
strong. *See* strong base.
weak. *See* weak base.
in DNA, 332
Lewis definition of, 622–627
nitrogenous, 956, *957*
pH of, 161–164
reaction with acids, 119–121
strengths of, 593, 595t
direction of reaction and, 601
base ionization constant (K_b) The equilibrium constant for the ionization of a base in aqueous solution, 593, 595t
relation to conjugate acid ionization constant, 597
base of logarithms, A-2
base pairing, hydrogen bonding and, 414
base units, SI, 23t
basic oxide(s) An oxide of a metal that acts as a base, 122
basic oxygen furnace, 866
basic solution A solution in which the concentration of hydronium ions is less than the concentration of hydroxide ion, 590
battery A device consisting of two or more electrochemical cells, 729
electrochemical, 712
energy per kilogram, 733t
lithium-ion, 445, 712, 732
types of, 730–731
bauxite, 823
Bayer process, 823
becquerel The SI unit of radioactivity, 1 decomposition per second, 998
Becquerel, Henri, 54
Beer-Lambert law The absorbance of a sample is proportional to the path length and the concentration, 175
Beethoven, Ludwig van, 833
belladonna, atropine in, 614
bends, 468
Benorz, Georg, 135
benzaldehyde, structure of, 925
benzene, boiling point elevation and freezing point depression constants for, 487t
derivatives of, 914, A-17
liquid and solid volumes, *406*

molecular orbital configuration of, 365
pi bonds in, 353, 913
reactions of, 915
resonance structures of, 299
standard enthalpy of formation of, 211
structure of, 913
vapor pressure of, 486
benzoic acid, 926t
buffer solution of, 639
pH in aqueous solution, 607
structure of, 914
benzonitrile, structure of, *899*
benzyl acetate, 929
benzyl butanoate, 928t
beryllium, abundance of, 817
electron configuration of, 257
similarity to aluminum, 822
beryllium dichloride, orbital hybridization in, 347
beta particle(s) An electron ejected at high speed from certain radioactive substances, 976
predicting emission of, 983
beta rays. *See* **beta particle(s)**.
bicarbonate ion, as acid, 121
concentration in sea water, 792, *793*
in biological buffer system, 645. *See also* hydrogen carbonate ion.
bidentate ligands, 870
bilayer structure, of lipids, 966
bimolecular process, 541
binary compound(s) A compound formed from two elements, 76
bonding types in, 854
binding energy The energy required to separate a nucleus into individual protons and neutrons, 984–987
per nucleon, 985
biochemistry, 944–973
thermodynamics and, 706
biodiesel, 788
biofuels, 787–789
biological effects of radiation, 1000
biomass, pH and, 800
biotechnology, 945
birefringence, *818*
bismuth, abundance of, 834
bisphenol A, 941
bituminous coal, 781
black powder, 214
black smokers, metal sulfides from, 96
blackbody radiation, 222
blast furnace, 865
bleach, detection in food tampering, 173
sodium hypochlorite in, 472, 851
blimp, helium in, 401
blood, buffers in, 636
oxygen saturation of, 371
pH of, 162, 645
boat form, 907
body-centered cubic (bcc) unit cell, 439
Bohr, Christian, 872
Bohr, Niels, 227
Bohr effect, in hemoglobin, 872
Bohr radius, *242,* A-13t
boiling point The temperature at which the vapor pressure of a liquid is equal to the external pressure on the liquid, 428
for common compounds, 424t, A-14t
hydrogen bonding and, 412
intermolecular forces and, 409
boiling point elevation, 486
boiling point elevation constant (K_{bp}), 486
Boltzmann, Ludwig, 391, 685
Boltzmann distribution curves. *See* Maxwell-Boltzmann distribution curves.
Boltzmann's constant, 685, A-13t
bomb calorimeter, 203
bombardier beetle, *514*
bond(s) An interaction between two or more atoms that holds them together by reducing the potential energy of their electrons, 283. *See also* bonding.
amide link, 930, 938
coordinate covalent, 303, 623, 870
covalent, 283
formation of, 283
glycosidic, 954
ionic, 284
multiple, 289
molecular geometry and, 313
peptide, 948
polar, 314–319
properties of, 326–331
sigma, 341
structural formulas showing, 64
wedge representation of, 65, 900
bond angle The angle between two atoms bonded to a central atom, 307
effect of lone pairs on, 309
in strained hydrocarbons, 907
bond dissociation energy. *See* bond energy.
bond dissociation enthalpy The enthalpy change for breaking a bond in a molecule, with the reactants and products in the gas phase at standard conditions, 328, 329t
of halogen compounds, 848t
bond energy, acid strength and, 618
activation energy and, 536
compared to nuclear binding energy, 985
in network solids, 828
of carbon–carbon bonds, 901
of noble gas compounds, 853
bond length The distance between the nuclei of two bonded atoms, 326, 327t
atomic radius and, 326
bond order and, 326
in benzene, 353
resonance structures and, 298
bond order The number of bonding electron pairs shared by two atoms in a molecule, 326
bond length and, 326
fractional, 326, 357
molecular orbitals and, 357
bond pair(s) Two electrons, shared by two atoms, that contribute to the bonding attraction between the atoms, 286
angles between, 307
in formal charge equation, 296
molecular polarity and, 320–325, 336t
bond polarity, electronegativity and, 314–319
formal charge and, 317
bond strength. *See* bond energy.
bonding, in carbon compounds, 896–943
in coordination compounds, 883–888
ligand field theory of, 883–888
metallic, band theory of, 452
molecular orbital theory of, 340, 354–365, 883
molecular structure and, 282–335
multiple, 289, 349–353
types of, 283–284
valence bond theory of, 340–354
van Arkel triangle diagram of, 854
bonding molecular orbital A molecular orbital in which the energy of the electrons is lower than that of the parent orbital electrons, 355
filling in transition metals, 864
boranes, 824
borate ion, structure of, *824,* 825
borax, *59,* 303, 822, 824
boric acid, 303, 825
in slime, *935*
Born, Max, 235, 451
Born-Haber cycle, 451, 478
boron, abundance of, 822
atomic weight of, 50
chemistry of, 822, 825
coordinate covalent bonds to, 303
in high-strength steel, 867
similarity to silicon, 822
boron carbide, *257*
in fireworks, 825
boron hydrides, 825
boron neutron capture therapy (BNCT), 1003
boron tetrafluoride ion, formal charges in, 317
boron trifluoride, molecular polarity of, 321
orbital hybridization in, 346
reaction with ammonia, 303
structure of, 318
borosilicate glass, 825
Bosch, Carl, 579
boundary surface, atomic orbital, 240

Boyle, Robert, 374, 381
Boyle's law, 374
  kinetic-molecular theory and, 395
brain, PET scans of, *1003*
Brandt, Hennig, 841
brass, bacteriocidal activity of, 278, 858
bread, specific heat capacity of, 185
breathing apparatus, closed-circuit, 815
brine, electrolysis of, 847
British thermal unit (Btu), A-8t
bromine, abundance of, 846
  atomic weight of, 50
  oxides of, 88
  physical states of, *7*
  production of, 847
  reaction with aluminum, 826
  reaction with nitrogen monoxide, 539
bromobenzene, mass spectrum of, *91*
2-bromooctane, reaction with iodine, 542
bromphenol blue, *636*
Brønsted, Johannes N., 116
Brønsted acid(s) A proton donor, 586
Brønsted base(s) A proton acceptor, 586
Brønsted–Lowry acid(s) A proton donor, 117
Brønsted–Lowry base(s) A proton acceptor, 117
bronze, 22
bubble gum, rubber in, 936
buckminsterfullerene ("buckyball"), 60, 709
buffer region, in titration of weak acid, 647
buffer solution(s) A solution that resists a change in pH when hydroxide or hydronium ions are added, 636–643
  biological, 645
  capacity of, 640
  common, 637t
  constant pH of, 642
  equations for, 638
  preparation of, 640
buret, *167*
1,3-butadiene, in styrene-butadiene copolymer, 936
  structure of, 909
butane, conversion to isobutane, 563, *575*
  structural isomers of, 903
butanone, 931
1-butene, structure of, 899, 908
2-butene, *cis* and *trans* isomers of, 899, 908
  iodine-catalyzed isomerization, 536
butter yellow dye, 366
butyl butanoate, 928t
butyric acid, 927t

cadaverine, 921
cadmium, in nickel-cadmium battery, 731
  in nuclear reactor, 996
cadmium sulfide, as pigment, 859
caffeine, 897
  extraction with supercritical carbon dioxide, 430
  structure of, *596*
calcite, ions in, *66*
calcium, abundance of, 817
  chemistry of, 817–821
  reaction with water, *818*
calcium carbonate, aquatic organisms and, *795*
  decomposition of, 209, 211, 213
    temperature and spontaneity, 702
  equilibrium with carbon dioxide in solution, *556*
  in iron production, 865
  in limestone, 102, 817
  precipitation from hard water, 820
  reaction with hydrochloric acid, 123, 164
  solubility of, *655*
  uses of, 819
calcium fluoride, 846, 849
  in fluorite, 817, 819
  solubility of, *657*
calcium hypochlorite, 851
calcium ion, reaction with oxalic acid, 631
calcium orthosilicate, 829
calcium oxalate, solubility of, 631
calcium oxide, 122
  uses of, 819
calcium phosphate, 842
calcium silicate, in blast furnace, 865
calcium sulfate, in gypsum, 75, 817
calculation, significant figures in, 36
calculator, pH and, 162
  logarithms on, A-2
  scientific notation on, 34
calibration plot, for spectrophotometric analysis, 175
calomel electrode, 747
caloric fluid, 183
calorie (cal) The quantity of energy required to raise the temperature of 1.00 g of pure liquid water from 14.5 °C to 15.5 °C, 27, A-8t
calorimetry The experimental determination of the enthalpy changes of reactions, 201–205
camphor, boiling point elevation and freezing point depression constants for, 487t
candela (cd), A-10
capacity, of buffer solution, 640
capillary action, 430
carat, 1
carbohydrate(s) An aldehyde or ketone containing multiple hydroxyl groups; sugar(s), 953–955
  biological oxidation of, 706
  energy content of, 28
carbon, abundance of, 827
  allotropes of, 59, *60*, 457, 709
  as reducing agent, 130t
  atomic mass unit relative to, 46
  binding energy per nucleon, 986
  comparison with silicon, 802
  electron configuration of, 257
  in compartments of global carbon cycle, *770*
  Lewis structures involving, 294
  nanotubes, 458
  organic compounds of, 896–943
  phase diagram of, 709
  radioactive isotopes of, 990
  removed from pig iron, 866
  trivalent, 581
carbon cycle, 769, *770*
carbon dioxide, acidification of sea water by, 792–796
  as greenhouse gas, 791
  as Lewis acid, 624
  bond order in, 326
  bonding in, 286
  density of, 384
  departure from ideal gas law, 400
  dissolved in Lake Nyos, 482
  enthalpy of formation, 205
  Henry's law constant, 480t
  in atmosphere, 769, *770*
  in biofuel production, 788

carbonic acid, 121
as polyprotic acid, 588t
in biological buffer system, 645
in ocean, 792
carbonic anhydrase, 540
carbonyl, naming carbon monoxide as ligand, 875
carbonyl group The functional group that characterizes aldehydes and ketones, consisting of a carbon atom doubly bonded to an oxygen atom, 922–931
carboxylate ion, resonance in, 621
carboxylic acid(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to another carbon atom and to a hydroxyl group, 924, 926
acid strengths of, 621
naming of, A-17
reaction with amine, 929
β-carotene, 494, 910
Carothers, Wallace, 937
cast iron, 865
catalase, *514*
catalyst(s) A substance that increases the rate of a reaction while not being consumed in the reaction, 513, 912
effect on reaction rates, 535–538
homogeneous and heterogeneous, 538
in green chemistry, 893
in Haber-Bosch process, 579
in petroleum refining, 785
in rate equation, 515
zeolites as, 832
catalytic converter, 790
catalytic RNA, 962
catalytic steam reformation, hydrogen production by, 811
cathode The electrode of an electrochemical cell at which reduction occurs, 723
in corrosion, 863
in electrolysis cell, 751
cathode rays, 54
cation(s) An ion with a positive electrical charge, 66
acid–base properties of, 598
as Brønsted acids and bases, 586
as Lewis acids, 623
naming, 71
noble gas electron configuration in, 264, 278
sizes of, 274
caves, sulfur-oxidizing bacteria in, 844
Cech, Thomas, 962
cell(s), electrochemical, 723–728
galvanic, 714
unit, 438
voltaic, 714, 723–728
cell division, DNA replication and, 958, *959*
cell membrane, lipids in, 966
cell potential, 734–743
cellulose, 955, *956*
Celsius temperature scale A scale defined by the freezing and boiling points of pure water, defined as 0 °C and 100 °C, 24
cement, green chemistry of, 831
centrifuge, isotope separation by, 997
cerium(IV) oxide, 891
cesium, abundance of, 812
melting point of, *59*
cesium chloride, crystal structure of, 445
CFC. *See* chlorofluorocarbons.
Chadwick, James, *55*, 994
chain reaction, free-radical, 548, 768
nuclear, 996
polymerase, 972
chair form, 907
chalcocite, 866
chalcogenides, 462
chalcogens, 61
chalcopyrite, 866
reaction with copper(II) chloride, 867
characteristic The part of a logarithm to the left of the decimal point, A-3
charcoal, in gunpowder, 214
charge, balancing in chemical equation, 113
balancing in ionic compounds, 68
conservation of, 715, 977
in Coulomb's law, 73
charge coupled device (CCD), 218
charge density, 413
charge distribution, in covalent compounds, 296
in molecules, 317
Charles, Jacques Alexandre César, 376, 381, 810
Charles's law, 376
kinetic-molecular theory and, 395
chelating ligand A ligand that forms more than one coordinate covalent bond with the central metal ion in a complex, 870
chemical analysis The determination of the amounts or identities of the components of a mixture, 84, 150–156
chemical bonds. *See* **bond(s)**, bonding.
chemical change(s) A change that involves the transformation of one or more substances into one or more different substances, 15–16. *See also* **reaction(s)**.
chemical compound(s). *See* **compound(s)**.
chemical energy The energy stored in chemical compounds, 17, 182
chemical equation(s) A written representation of a chemical reaction, showing the reactants and products, their physical states, and the direction in which the reaction proceeds, 16, 97–99
balancing, 99–102, 715–722
manipulating, equilibrium constant and, 572
chemical equilibrium, factors affecting, 575–581
chemical kinetics The study of the rates of chemical reactions under various conditions and of reaction mechanisms, 506–553
chemical property, 16
chemical reaction(s). *See* **reaction(s)**.
chemical vapor deposition (CVD), 709
chemistry, green. *See* green chemistry.
methods of, 3–5
organic, 896–943
chemocline, 482
Chernobyl, 997
china clay, 830
chiral compound A molecule that is not superimposable on its mirror image, 879, 900. *See also* **enantiomers**.
α-amino acids as, 946
center of chirality of, 905
optical activity of, 900
chlor-alkali industry, 815
chloramine, 775
Lewis electron dot structure of, 288
chlorate ion, 72
formal charges in, 297
Lewis electron dot structure of, 291
chloric acid, 850
chlorination, disinfection by, 773, 775
chlorine, abundance of, 846
as disinfectant, 773, 775
coordinate covalent bonds to, 303
departure from ideal gas law, 401
oxoacids of, 850
production by aqueous sodium chloride electrolysis, 755, 813, 847
reaction with alkanes, 906
reaction with methane, 548
reaction with nitrogen monoxide, 516
reaction with phosphorus, 97, *98*, 139
reaction with sodium, 3, 284
chlorine demand, 775
chlorine difluoride ion, molecular geometry of, 311
chlorine dioxide, 775
chlorite ion, 72
chlorobenzene, structure of, 914
chlorofluorocarbons (CFCs), 768, 792
chloroform, boiling point elevation and freezing point depression constants of, 487t
Lewis structure of, 287
chloromethane, as refrigerant, 768
reaction with silicon, 832
chlorophyll, 971
magnesium in, 821
chlorous acid, 850
chocolate, 896
cholesterol, structure of, 966

choline, in phospholipid, *966*
chromatography, 432
chromium, water pollution by, *775*
chromium(III) chloride hexahydrate, 411
chromium(III) ion, in ruby, 248
cinnabar, 3, *658*
cinnamaldehyde, structure of, *925*
circle, area of, 42
cisplatin, discovery of, 882
  rate of substitution reaction, *516*
cis-trans isomers, 352, *536*, 899
  cisplatin, 882
  in coordination compounds, 878
citric acid, 926t
  reaction with sodium hydrogen carbonate, 130
  structure of, *596*
Clapeyron, Émile, 428
Clausius, Rudolf, 428
Clausius–Clapeyron equation, 427
clay(s), 830
Clean Air Act, 790
cleavage, of crystalline solids, 459
cleavage reaction, enzyme-catalyzed, 952
climate change, carbon dioxide and, 769
  greenhouse gases and, 394, 792
clinker, in cement production, 831
clock reaction, iodine, *513*
cloning, genetic, 944
close packing, in crystal lattice, 442
clown fish, 19
coagulation, of colloids, 499
coal, as energy resource, 778
  capturing carbon dioxide from, 794
  types of, 781t
coal tar, aromatic compounds from, 913t
cobalt, colors of complexes of, 891t
cobalt-60, use in cancer treatment, 1003
cobalt(II) chloride, reaction with hydrochloric acid, *554*
cobalt(II) chloride hexahydrate, 75, *411*
Cockcroft, J. D., 994
cocoa, 896
codon A three-nucleotide sequence in mRNA that corresponds to a particular amino acid in protein synthesis, 960
coefficient(s), stoichiometric, 98, *559*, 571
cofactors, enzyme, 963
coffee, decaffeination with supercritical carbon dioxide, 430
coffee-cup calorimeter, 201
cohesive force A force of attraction between molecules of a single substance, 431
coinage metals, 22
coke, in iron production, *865*
  in refining of silicon, 828
  production from coal, 781
colligative properties The properties of a solution that depend only on the number of solute particles per solvent molecule and not on the nature of the solute or solvent, 470, 484–497
  of solutions of ionic compounds, 495–497
Collins, Terry, 893
collision theory A theory of reaction rates that assumes that molecules must collide in order to react, 530–538
colloid(s) A state of matter intermediate between a solution and a suspension, in which solute particles are large enough to scatter light but too small to settle out, 498–501
  types of, 499
color(s), of acid–base indicators, *653*, *655*
  of coordination compounds, 888–893
  of fireworks, 233
  of gemstones, 248, 859
  of glass, 859
  of transition metal compounds, 623, *624*, 859
  pi bonding and, 366
  visible light, *221*, 888
Colorado River, depletion of, 771
combined available chlorine, *775*
combined gas law. *See* general gas law.
combustion analysis, determining empirical formula by, 152–156
combustion calorimeter, 203
combustion reaction The reaction of a compound with molecular oxygen to form products in which all elements are combined with oxygen, 100
  of hydrocarbons, 780
  of organic compounds, 901
  spontaneity of, *695*
common ion effect The limiting of acid (or base) ionization caused by addition of its conjugate base (or conjugate acid), 632–635
  solubility and, 661–664
common logarithms, A-2
common names, of binary compounds, 77
  of organic compounds, 905, A-15
compact fluorescent bulb, europium in, 891
complementary strands, in DNA, 958
completion, reaction going to, *561*
complex(es), 623. *See also* **coordination complex(es)**; **coordination compound(s)**.
  in enzyme-catalyzed reaction, *540*
  solubility and, 662, 670–674
compound(s) Matter that is composed of two or more kinds of atoms chemically combined in definite proportions, 11
  binary, naming, 76
  coordination. *See* **coordination compound(s)**.
  covalent, 285
  determining formulas of, 84–92
  hydrated, 75, 411, 868
  ionic, 65–75
    naming, 72
  molar mass of, 80
  molecular, 76
  odd-electron, 305
  organic, 896–943
  organic, stability of, 901
  saturated, 902
  specific heat capacity of, 185t
  standard molar enthalpy of formation of, 208
  volatile organic, 792
compressibility The change in volume with change in pressure, 374
concentration(s) The amount of solute dissolved in a given amount of solution, 156
  determination by cell potential, 745
  determination by spectrophotometric analysis, 176
  effect on equilibrium of changing, *575*
  graph of, determining reaction rate from, 508
  in collision theory, 530
  in equilibrium constant expressions, *557*
  known, preparation of, 159
  measurement by osmotic pressure, 491
  of ions in solution, 158
  partial pressures as, *559*
  rate of change, 506–553
  reaction rate and, 515–520
  relation to absorbance, 175
  units of, 471
concrete, 831
condensation The state change from gas to liquid, 421
  intermolecular forces and, 409
condensation polymer(s) A synthetic organic polymer formed by combining monomer units in such a way that a small molecule, usually water, is eliminated, 932, 937–939
  silicone, 832
condensation reaction(s) A reaction in which parts of the reactant molecules bond together and a small molecule, usually water, is eliminated, 937
  of amino acids, 948
  of monosaccharides, 954
condensed formula A variation of a molecular formula that shows groups of atoms, 64, 900
condition(s), standard. *See* **standard state**.
conduction band, 454

conductivity, electrical, of molecular solids, 456
electrical, of solutions, 106
conductor(s), band theory of, 452
conjugate acid–base pair(s) A pair of compounds or ions that differ by the presence of one hydrogen ion, 588
in buffer solutions, 636
ionization constants of, 597
strengths of, 594
conservation law, charge, 715
energy, 18, 182
mass, 4, 715
matter, 98
constant composition, law of, 12
constant(s), acid and base ionization, 593, 595t
boiling point elevation, 486
Boltzmann, 685
equilibrium, 557–564
relation to rate equation, 546–548
Faraday, 744, 757
formation, 671
freezing point depression, 488
gas, 382, 491, 533
Henry's law, 480t
physical, A-13t
Planck's, 222
rate, 515, 516
Rydberg, 227
significant figures in, 35
solubility product, 656
van der Waals, 400t
water ionization, 589
continuous spectrum The spectrum of white light emitted by a heated object, consisting of light of all wavelengths, *221, 223,* 227
conversion factor(s) A multiplier that relates the desired unit to the starting unit, 26, 38, A-9
energy units, A-8t
in mass/mole problems, 79
in pressure problems, 373
pressure units, A-7t
SI units, 24
coordinate covalent bond(s) Interatomic attraction resulting from the sharing of a lone pair of electrons from one atom with another atom, 303, 623, 870
coordination complex(es) An ion in which a metal ion or atom is bonded to one or more molecules or anions to compose a structural unit, 623, 870
equilibria of, 670–674
formation constants of, 671, A-25
coordination compound(s) A compound containing a coordination complex, 870
bonding in, 883–888
colors of, 888–893
formulas of, 871–874
magnetic properties of, 886
naming of, 874
spectrochemical series of, 890–893
structures of, 876–882
coordination geometry The arrangement in space of the central metal atom or ion in a coordination compound and the ligands attached to it, 870
coordination isomers Two or more complexes in which a coordinated ligand and a noncoordinated counterion are exchanged, 877
coordination number The number of ligands attached to the central metal atom or ion in a coordination compound, 870
molecular geometry and, 876
copernicium-277, radioactive half-life, 988
Copernicus, Nicolaus, 12
copolymer A polymer formed by combining two or more different monomers, 936
copper, 22
antimicrobial properties, 856–858
biochemistry of, 278
electrolytic refining, 868
ores of, *864*
oxidation by sea water, 758
production of, 866
reaction with nitric acid, 837
reaction with silver ions, 126, 713–716
copper(I) chloride, disproportionation of, 868
in fireworks, 233
copper(II) carbonate, *656*
copper(II) chloride, dissociation of, 158
reaction with chalcopyrite, 867
copper(II) ion, complexes of, 623, *624*
successive equilibria with ammonia, 671
copper(II) sulfate pentahydrate, 90
coral, calcium carbonate in, *115*
core electrons The electrons in an atom's completed set of shells, 256, 262, 285
molecular orbitals containing, 358
corn, ethanol production from, 212
corrosion The deterioration of metals by oxidation–reduction reactions, 863
of aluminum, 823
corundum, 826
cosmic radiation, 999
coulomb (C) The quantity of charge that passes a point in an electric circuit when a current of 1 ampere flows for 1 second, 734, 757, A-7, A-11
Coulomb's law The force of attraction between the oppositely charged ions of an ionic compound is directly proportional to their charges and inversely proportional to the square of the distance between them, 73
Bohr equation and, 228
ion–dipole attractions and, 407
ion pair attraction energy and, 449
counterion(s) An ion in a coordination compound that is not part of the coordination complex, but is present for charge balance, 873
in coordination isomers, 877
covalent bond(s) An interatomic attraction resulting from the sharing of electrons between the atoms, 283, 854
polar and nonpolar, 314–319
valence bond theory of, 340–354
covalent compound(s) A compound formed by atoms that are covalently bonded to each other, 285
covalent radius, 268
covellite, 866
cracking, in petroleum refining, 763, 785
Crick, Francis, 333, 414, 958
critical point The upper end of the curve of vapor pressure versus temperature, 429
critical pressure The pressure at the critical point, 429
critical temperature The temperature at the critical point; above this temperature the vapor cannot be liquefied at any pressure, 429
crocoite, *656*
Crookes, William, 54
cross-linked polyethylene (CLPE), 934
cross-linking, in vulcanized rubber, 935
cryolite, 819
in fireworks, 233
in Hall-Heroult process, 824, 849
crystal lattice A solid, regular array of positive and negative ions, 73, 437–444
crystallites, in steel, 867
crystallization, colloids and, 498
heat of, 474
temperature change and, 483
cubic centimeter (cm^3), 27
cubic close-packed (ccp) unit cell, 442
cubic decimeter (dm^3), 27
cubic meter (m^3), 27
cubic unit cell A unit cell having eight identical points at the corners of a cube, 439
lead(II) sulfide, *665*
cuprite, 22
curie A unit of radioactivity, 998
Curie, Marie and Pierre, 54, 61, 845, 979
curium, 54
current, electric, unit of, 757
Cusumano, James, 5
cyanate ion, resonance structures, 318
cyanide ion, reaction with water, 118
cyanobacteria, 766
cyanuric acid, hydrogen bonding with melamine, 422
cycloalkanes, 907
general formula of, 902t
naming of, A-16

cyclobutane, structure of, 907
cyclohexane, structure of, 907
cyclohexene, structure of, 909
cyclopentane, structure of, 898
cyclopropane, conversion to propene, 521
  structure of, 907
cysteine, molecular geometry of, 313
  structure of, 65, *947*
cytosine, 332
  hydrogen bonding to guanine, 414, 958
  in DNA and RNA, 956, *957*
  structure of, 282

d orbital(s). *See also* **atomic orbital(s)**.
  hybrid orbitals and, 364
  in bonding of third-period elements, 305
  in coordination compounds, 883
Dacron, 937
Dalton, John, 46, 54, 387
Dalton's law of partial pressures The total pressure of a mixture of gases is the sum of the pressures of the components of the mixture, 387
data, graphing of, 39–41
dating, isochron, 1006
  radiocarbon, 990
Davisson, C. J., 234
Davy, Humphry, 754, 758, 813
d-block elements, properties of, 858
de Broglie, Louis Victor, 234
Debye, Peter, 320
debye unit, 320
decay constant, for radioactivity, 989
decay series, radioactive, 978
deciliter (dL), 27
decimal point, in conversion between fixed and exponential notation, 32
decomposition, determining molecular formula by, 88
decomposition reaction(s) A reaction in which a compound is taken apart into smaller constituents, 133
Deepwater Horizon oil spill, 796
defined quantity, significant figures in, 35
definite proportions, law of, 12
delocalization, molecular orbital, 452
delta (D), symbol for change, 185
delta (d), symbol for partial charge, 315
denitrification, by bacteria, 838
density The ratio of the mass of an object to its volume, 13
  balloons and, *383*
  of air, 384
  of gas, calculation from ideal gas law, 383
  of sulfuric acid in lead storage battery, 731
  of transition elements, 862
  unit cell dimensions and, 448
  units of, 13
dental amalgam, 741
deoxyribonucleic acid, 956
  amplification by polymerase chain reaction, 972
  bonding in, 282
  hydrogen bonding in, 414
  in cloning, 944
  molecular geometry of, 332
  synthetic, 958
deoxyribose, 953, 956, *957*
2-deoxyribose, structure of, 282, 332
derived units, SI, A-11
desalination, by reverse osmosis, 492, 774
detergents, 500
  phosphates in, 774
deuterium, 48, 809
  binding energy of, 985
  fusion of, 998
  preparation of, 810
diagonal relationship, in periodic table, 822
diamagnetism The physical property of being repelled by a magnetic field, 264, 886
diamminedichloroplatinum(II), isomers of, 878
diamond, as insulator, 455
  interatomic distances in, *26*
  structure of, 59, *60*
  synthesis of, 459, 709
diatomic molecule(s), atomic radii in, 268
  heteronuclear, 362
  homonuclear, 358
  of elements, *60*
diberyllium cation, 358
diborane, 825
  hybridization in, 364
dibromine pentaoxide, 89
1,2-dichlorobenzene, 914
dichlorodifluoromethane, 768
1,2-dichloroethylene, isomers of, 352
  molecular polarity of, 324
dichlorotetrafluoroethane, 768
dichromate ion, as oxidizing agent, 130t
  reaction with ethanol, 130
diene(s) A hydrocarbon containing two double bonds, 910
  naming of, A-16
dietary Calorie, 27
diethyl ether, 918
  vapor pressure curves for, *426*
diethyl ketone, 925t
diffraction, of electrons, 234
  of x-rays by crystals, 441
diffusion The gradual mixing of the molecules of two or more substances by random molecular motion, 396
  probability and, 685–687
  through cell membrane, 967
digital camera, charge coupled device in, 218
dihelium, molecular orbital energy level diagram of, 357
dihydrogen phosphate ion, amphiprotic nature of, 587
  buffer solution of, 637t
  L-3,4-dihydroxyphenylalanine (L-DOPA), 923
diiodocyclohexane, dissociation of, 566
dilithium, molecular orbital energy level diagram of, 358
dilution, buffer pH and, 642
  isotope, 1003
  preparation of solutions by, 159
  serial, 162
dimensional analysis A general problem-solving approach that uses the dimensions or units of each value to guide you through calculations, 26, 38
dimethyl ether, structure of, 64, 413, 899
dimethyl sulfide, 845
1,3-dimethylbenzene, 914
dimethylbutane, structural isomers of, 904
dimethylglyoximate ion, *671*
dimethylglyoxime, as ligand (dmg), 869, 877
dimethylphthalate (DMT), in recycling PET plastic, 938
2,2-dimethylpropane, structure of, 903
1,4-dinitrobenzene, 914
dinitrogen, bonding in, 286
  photoelectron spectrum of, 367
dinitrogen monoxide, 765, 835
  as greenhouse gas, 791
dinitrogen pentaoxide, 836
  decomposition of, 508
    rate equation, 515, 529
dinitrogen tetraoxide, 836
  decomposition of, 578
dinitrogen trioxide, 836
dioxovanadium(V) ion, reaction with zinc, 718
dioxygen. *See* oxygen.
dipolar bond. *See* **polar covalent bond**.
dipole(s), induced, 416
dipole moment (μ) The product of the magnitude of the partial charges in a molecule and the distance by which they are separated, 320, 321t
dipole–dipole attraction The electrostatic force between two neutral molecules that have permanent dipole moments, 409
dipole–induced dipole attraction The electrostatic force between two neutral molecules, one having a permanent dipole and the other having an induced dipole, 416
diprotic acid, 117
disaccharides, 954
disinfection, of water, 773
Disinfection Byproducts Rule (DBR), 775
disintegrations per second (dps), 998

dispersant, for cleaning spilled oil, 797
dispersion(s), colloidal, 498
dispersion forces Intermolecular attractions involving induced dipoles, 417
disproportionation reaction, 850
dissociation, of electrolytes in solution, 106
dissolved carbon, 800
distillation, in petroleum refining, 763, 785
  Raoult's law and, 502
diving, pressure and solubility in, 468
DNA. *See* deoxyribonucleic acid.
Dolly the Sheep, 944
dolomite, 817
domain, ferromagnetic, 266
donor level, in semiconductor, 456
dopamine, 923
dopant, in semiconductor, 455
double bond A bond formed by sharing two pairs of electrons, one pair in a sigma bond and the other in a pi bond, 289
  in alkenes, 907
  melting point of triglycerides and, 965
  rotation around, 536, 899
  valence bond theory of, 349
double displacement reaction(s). *See* **exchange reaction(s)**.
double helix, in DNA structure, 958
Downs cell, for producing sodium, 813, *814*
dry cell battery, 730
dry ice, 193, 465
d-to-*d* transition, 890
ductility, metallic, 454
dye(s), green chemistry of, 366
  pH indicating, 162
  rate of reaction with bleach, *508*, 510
dynamic equilibrium, in solution process, 473
  molecular description of, 104
  vapor pressure and, 425
dynamite, *919*

earth, alchemical meaning of, 817
effective atomic number (EAN) rule. *See* **18-electron rule**.
effective nuclear charge (*Z)** The nuclear charge experienced by an electron in a multielectron atom, as modified by the other electrons, 252, 253t, 262
  atomic radius and, 269
effusion The movement of gas molecules through a membrane or other porous barrier by random molecular motion, 397
Ehrlich, Paul, 90
Eiffel Tower, 32
Einstein, Albert, 223, 985
eka-silicon, 57
elastomer(s) A synthetic organic polymer with very high elasticity, 935
electric current, unit of, 757
electric field, polar molecules aligned in, 320
electrical energy The energy due to the motion of electrons in a conductor, 17
electroactive substance, 753, 755
electrochemical cell(s) A device that produces an electric current as a result of an electron transfer reaction, 723–728
  commercial, 729–733
  corrosion and, 863
  nonstandard conditions for, 744–747
  notation for, 727
  potential of, 734–743
  work done by, 747
electrochemistry, 713
electrode(s) A device such as a metal plate or wire for conducting electrons into and out of solutions in electrochemical cells, 106, 723
  hydrogen, 726
  inert, 726
  pH, 162, *163*
  standard hydrogen, 735
  terminology for, 752
electrolysis The use of electrical energy to produce chemical change, 715, 751–756
  aluminum production by, 823, 824
  electrodes in, 752
  fluorine production by, 847
  hydrogen produced by, 810, 811
  of aqueous solutions, 753
  of magnesium chloride, 818
  of sodium chloride, 386, 752, *816*
  of water, 10
  oxygen production by, 843
electrolyte(s) A substance that ionizes in water or on melting to form an electrically conducting solution, 106–107
electromagnetic radiation Radiation that consists of wave-like electric and magnetic fields, including light, microwaves, radio signals, and x-rays, 220
  gamma rays as, 976
electromotive force (emf), 734
electron(s) (e^-) A negatively charged subatomic particle found in the space about the nucleus, 45
  as beta particle, 976
  as cathode rays, 54
  assignment to atomic orbitals, 251–254
  balancing in half-reaction method, 715
  bond pair, 286
  charge of, measurement of, 55, A-13t
  charge-to-mass ratio of, 54
  configuration. *See* electron configuration(s).
  core, 256, 285
  core, molecular orbitals containing, 358
  counting, 757
  delocalization of, 452. *See also* **molecular orbital theory**.
  diffraction of, 234
  in electrochemical cell, direction of flow, 735
  in photoelectric effect, 223
  in voltaic cell, direction of flow, 723
  lone pair, 286. *See also* **lone pair(s)**.
  mass of, A-13t
  nuclear charge experienced by, 252
  octet of, 286
  quantization of potential energy, 227, 236
  sharing in Lewis acid–base reactions, 623
  shells and subshells, 237, 251t
  spin. *See* electron spin.
  transfer in oxidation–reduction reactions, 126
  valence, 256, 285. *See also* **bond pair(s)**, **lone pair(s)**.
    of main group elements, 805
    repulsions of, 307. *See also* **valence shell electron-pair repulsion (VSEPR) model**.
  wave properties of, 234
  wavelength of, 234
electron affinity The negative of the internal energy change occurring when an atom of the element in the gas phase gains an electron, 272
electron attachment enthalpy ($D_{EA}H$) The enthalpy change occurring when an atom of the element in the gas phase gains an electron, 271
  acid strength and, 618
  values of, A-18
electron capture A nuclear process in which an inner-shell electron is captured, 980
  predicting, 983
electron cloud pictures, 239
electron configuration(s), in coordination compounds, 885
  Lewis notation for, 285
  main group, 256–258
  noble gas notation for, 256
  of elements, 255t
  of heteronuclear diatomic molecules, 362
  of homonuclear diatomic molecules, 360
  of ions, 263–266
  of transition element ions, 264
  of transition elements, 260, 263, 859, 860t
  orbital box notation for, 250
  spdf notation for, 256
electron density, in molecules, 322
electron dot symbols. *See* **Lewis electron dot symbol/structure(s)**.
electron spin, quantization of, 243
electron spin quantum number, 243
electron transfer reaction(s). *See* **oxidation–reduction reaction(s)**.
electron-deficient molecule, 364, 825

electronegativity (χ) A measure of the ability of an atom in a molecule to attract electrons to itself, 315, 334
central atom in Lewis electron dot structure and, 287
hydrogen bonding and, 412
in van Arkel-Ketelaar triangle, 854
Pauling equation for, 334
electroneutrality, principle of, 317
electron-pair geometry The geometry determined by all the bond pairs and lone pairs in the valence shell of the central atom, 309
orbital hybridization and, 342
electroplating, 751
electrostatic energy The energy due to the separation of electrical charges, 18
electrostatic force(s) Forces of attraction or repulsion caused by electric charges, 73
electrostatic potential surface, 322
element(s) Matter that is composed of only one kind of atom, 10
abundances of, 803
in Earth's crust, 59t
atomic number of, 46
atomic weight of, 50
d-block, 858
diatomic molecules of, *60*
electron attachment enthalpy values of, A-18
electron configurations of, 255t
f-block, 858
ionization energies of, A-18
isotopes of, 48–50
line emission spectra of, 227
main group, 53, *56*
chemistry of, 802–855
molar mass of, 78, *79*
monatomic ions of, charges on, 66–68
monatomic ions of, sizes of, 274
names of, 10, 12
oxidation number of zero, 127
p-block, 257
molecular orbitals involving, 359
periodic table of, 52–63
s-block, 257
sources of, *864*
specific heat capacity of, 185t
standard enthalpy of formation of, 209
standard enthalpy of vaporization of, 424t
standard molar free energy of formation of, 700
symbol for, 47
synthesis of, 993
transition, 53, *56*, 62. *See also* transition elements.
transuranium, 993, *995*
elementary step A simple event in which some chemical transformation occurs; one of a sequence of events that form the reaction mechanism, 541
rate equation for, 541
elephants, frontalin in, 901
eluent, 433
emission spectrum, excited states and, *230*
of elements, 227
empirical formula A molecular formula showing the simplest possible ratio of atoms in a molecule, 85–88
determination by combustion analysis, 152–156
relation to molecular formula, 87
emulsifying agent, 500
emulsion A colloidal dispersion of one liquid in another, 498t, 500
enantiomers A stereoisomeric pair consisting of a chiral compound and its mirror image isomer, 879, 900
of α-amino acids, 948
end point. *See* **equivalence point**.
endocytosis, 968
endothermic process A thermodynamic process in which heat flows into a system from its surroundings, 184, 680
enthalpy change of, 196
equilibrium constant of, 578
in metabolism, 969
energy The capacity to do work and transfer heat, 182–184
activation. *See* **activation energy**.
alternative sources of, 784–789
binding, 984–987
chemical, 182
color of photons and, 224
conversion of forms of, 18
density, in batteries vs. gasoline, 733t
direction of transfer, 182
dispersal of, 682–687
effect on equilibrium, 481
exchange, electron configuration and, 257, 263
from combustion of hydrocarbons, 780
global usage, 779
in food, 28, 180, 968
internal, 194
ionization. *See* **ionization energy**.
kinetic, distribution in gas, 391, 532
distribution in liquid, 422
of alpha and beta particles, 977
lattice, 449–452
law of conservation of, 18, 182
levels in hydrogen atom, 228, 231
mass equivalence of, 985
nuclear, 996
quantization of, 227, 236, 684
relation to frequency of radiation, 222
sources for human activity, 181
state changes and, 189–192
supply and demand, 777
thermal, 182
units of, 27–28, A-7
energy level diagram, 206
Born-Haber cycle, 451
dissolution of ionic solid, 477
enthalpy (H) The sum of the internal energy of the system and the product of its pressure and volume, 195–197
bond dissociation, 328
effect on acid strength, 619
entropy and, in spontaneous reaction, 694t
in Gibbs free energy, 696
enthalpy change (ΔH) Heat energy transferred at constant pressure, 196, 680
as state function, 197
calculations with, 205–211
for chemical reactions, 198–201
measurement of, 201
sign conventions for, 196
enthalpy of formation, of alkali metals, 814
standard molar, 208, A-26
enthalpy of fusion ($\Delta_{fus}H$) The energy required to convert one mole of a substance from a solid to a liquid at constant temperature, 460, 461t, A-14t
enthalpy of hydration, 408
enthalpy of solution ($\Delta_{soln}H$) The amount of heat involved in the process of solution formation, 475–479
calculation of, 478
enthalpy of solvation, 408
enthalpy of sublimation ($\Delta_{sublimation}H$) The energy required to convert one mole of a substance from a solid to a gas, 463
enthalpy of vaporization ($\Delta_{vap}H$) The quantity of heat required to convert 1 mol of a liquid to a gas at constant temperature, 423, 424t, A-14t
intermolecular forces and, 409, 410t
of nonpolar substances, 417t, 424t
relation to vapor pressure, 427
entropy (S) A measure of the disorder of a system, 682
effect on acid strength, 619
in Gibbs free energy, 696
molecular structure and, 688
physical state and, 688
second law of thermodynamics and, 691
solution process and, 475, *476*
standard molar, 687
statistical basis of, 684
entropy change (ΔS), for universe, system, and surroundings, 691
of reaction, 689
environment, chemistry of, 762–801. *See also* green chemistry.
enzyme(s) A biological catalyst, 513, 951
catalysis by, 540
methylphosphonate ion production and, 394
enzyme cofactors, 963
epichlorohydrin, structure of, 941
epinephrine, 923
epoxy resins, 941
equation(s), Arrhenius, 533
Balmer, 227
Beer-Lambert law, 175
Bohr, 228
boiling point elevation, 486
Boltzmann, 685
bond order, 326, 357
Boyle's law, 375

  reversibility and, 682
  solution process as, 473
  successive, 671
  thermal, 182
equilibrium constant (*K*) The constant in the equilibrium constant expression, 547, 557–564
  calculating from initial concentrations and pH, 605
  calculating from standard potential, 749
  calculations with, 567–571
  concentration vs. partial pressure, 559
  determining, 564
  for product-favored vs. reactant-favored reactions, 104, 561
  for weak acid and base (K_a and K_b), 592–598
  Gibbs free energy change and, 698
  relation to reaction quotient, 562
  relation to standard free energy of change of reaction, 704
  simplifying assumption in, 569, 607, A-5
  unitless, 559
equilibrium constant expression A mathematical expression that relates the concentrations of the reactants and products at equilibrium at a particular temperature to a numerical constant, 558
  for gases, 560, 567
  reverse reaction, 572
  stoichiometric multipliers and, 572–574
  sum of reactions, 572
equilibrium vapor pressure The pressure of the vapor of a substance at equilibrium in contact with its liquid or solid phase in a sealed container, 425
  in phase diagram, 463
equivalence point The point in a titration at which one reactant has been exactly consumed by addition of the other reactant, 167
  of acid–base reaction, 644, 647, 650, 654
error The difference between the measured quantity and the accepted value, 29
ester(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to another carbon atom and to an oxygen atom that is attached to another organic group, 788, 924, 927
  hydrolysis of, 928
  naming of, A-17
esterification reaction A reaction between a carboxylic acid and an alcohol in which a molecule of water is formed, 927
ethane, enthalpy of combustion, 200
  Henry's law constant, 480t
  structure of, 898
1,2-ethanediol, 918
ethanol, 918
  as biofuel, 787
  as fuel, 212
  as nonelectrolyte, 107
  hydrogen bonding in, 413
  iodine solubility in, 417
  mass spectrum of, *91*
  miscibility with water, 474
  oxidation to acetic acid, 924
  reaction with dichromate ion, 130
  standard molar enthalpy of formation of, 209
  structure of, 64, 899
  vapor pressure curves for, *426*
ethene. *See* ethylene.
ether(s) Any of a class of organic compounds characterized by the presence of an oxygen atom singly bonded to two carbon atoms, 918
ethyl acetate, 927
ethylene, 908
  derivatives of, as monomers, 933t
  orbital hybridization in, 349
  production of, 785
  reaction with water, 918
  separation by metal-organic framework, 763
  structure of, 898
ethylene glycol, 918
  as antifreeze, 472, 488, 920
  as nonelectrolyte, 107
  reaction with terephthalic acid, 937
  specific heat capacity of, 185t
1,2-ethylenediamine, as ligand (en), 870
  reaction with succinic acid, 939
ethylenediaminetetraacetate ion ($EDTA^{4-}$), as ligand, 871
ethyne. *See* acetylene.
eugenol, 487
europium, *62*
  in phosphors, 279
  uses of, 891
evaporation. *See also* **vaporization**.
  entropy change for, 690
  intermolecular forces and, 409
exact number, significant figures in, 35

exchange energy, Hund's rule and, 257, 263
exchange reaction(s) A chemical reaction that proceeds by the interchange of reactant cation–anion partners, 110
excited state The state of an atom in which at least one electron is not in the lowest possible energy level, 228
  nuclear, 977
exclusion principle. *See* **Pauli exclusion principle**.
exothermic process A thermodynamic process in which heat flows from a system to its surroundings, 184, 680
  enthalpy change of, 196
  equilibrium constant of, 578
  in metabolism, 969
  in nuclear fission, 996, 998
expansion molding, polystyrene, 935
exponent, 32
exponential notation, 32, A-2
extensive properties Physical properties that depend on the amount of matter present, 14
extrinsic semiconductor, 455

f orbital(s). *See* **atomic orbital(s)**.
face-centered cubic (fcc) unit cell, 439, 442
facilitated diffusion, through cell membrane, 968
factor-label method. *See* **dimensional analysis**.
Fahrenheit temperature scale A scale defined by the freezing and boiling points of pure water, defined as 32 °F and 212 °F, *24*
family, in periodic table. *See* **group(s)**.
Faraday, Michael, 754, 913
Faraday constant (*F*) The proportionality constant that relates standard free energy of reaction to standard potential; the charge carried by one mole of electrons, 744, 757, A-13t
fat(s), as lipids, 965
  energy content of, 28
  reaction with methanol, 789
  unsaturated, *911*
fatty acid(s), 965
feldspar, 832
fermentation, anaerobic, 918
Fermi, Enrico, 994
Fermi level The highest filled electron energy level in a metal at absolute zero temperature, 453
ferrite, unit cell of, 867
ferromagnetism The physical property of certain solids in which the spins of unpaired electrons in a cluster of atoms are aligned in the same direction, 266
  of lanthanides, 279
fertilizer, ammonia in, 579
  nitrogen cycle and, 765
Fe-TAML®, 893
fiber, dietary, *955*
filling order, of electron subshells in atoms, 251
  of orbitals in molecular orbital theory, *356*
film badge, radiation monitoring, *1000*

fission The highly exothermic process by which very heavy nuclei split to form lighter nuclei, 974, 996
fixed notation, 32
flame test, *233*
flash memory, 462
flash photolysis, 550
Fleming, Alexander, 951
flerovium, 993
flex-fuel cars, 788
flotation, for ore treatment, 866
fluid, 6
  supercritical, 429, 465
fluid-mosaic model, of cell membrane, 967
fluorescence, 847
fluoride ion, in drinking water, 776
fluorine, abundance of, 846
  bonding in, 286
  chemistry of, 848–850
  compounds of, hydrogen bonding in, 412
  electron configuration of, 258
  oxidation number of, 127
  production of, 846
  reaction with nitrogen dioxide, 544
  reaction with xenon, 852
  sigma bond in, 341
fluorite, *258*, 657, 658, 667, 817, 819
  ions in, *66*
fluoroapatite, 821
fluorosis, 776
fluorosulfonic acid, 627
fluorspar, *258*, 846, 849
flux, borax as, 825
  cryolite as, 823
  fluorspar as, 846
foam, 498t
food, energy content of, 28, 180, 968
  irradiation, 1005
  proteins in, 422
  tampering, titration for detecting, 173
fool's gold. *See* iron pyrite.
force(s), A-6
  intermolecular. *See* **intermolecular forces**.
formal charge The charge on an atom in a molecule or ion calculated by assuming equal sharing of the bonding electrons, 296
  bond polarity and, 317
  relation to acid strength, 620
formaldehyde, 925t
  Lewis electron dot structure of, 289
  orbital hybridization in, 350
  released by synthetic adhesives, 940
  structure of, 923
formation, standard molar enthalpy change of, 208
  standard molar free energy of, 700
formation constant An equilibrium constant for the formation of a complex ion, 671, A-25
formic acid, 927t
  as weak acid, 594
  in water, equilibrium constant expression for, 572
  Lewis structure of, 295t
  pH in aqueous solution, 609
  reaction with sodium hydroxide, 604
formula(s), chemical, 12
  condensed, 900
  empirical, 85–88, 152
  general, of hydrocarbons, 902t
  molecular, 900. *See also* molecular formula.
  of ionic compounds, 68–71
    structures and, 444–449
  perspective, 900
  predicting, 805–809
  structural, 900, 905. *See also* structural formula.
formula mass, 81
formula unit The simplest ratio of ions in an ionic compound, similar to the molecular formula of a molecular compound, 81
fossil fuels, 778–784
  environmental impact of, 789–796
fracking. *See* hydraulic fracturing.
fractional abundance of isotopes, 51
fractional distillation, 502
fragment ion, in mass spectra, *91*
francium, abundance of, 812
Franklin, Rosalind, 333, 414

free available chlorine, 775
free energy. *See* **Gibbs free energy**.
free energy change (DG), 696
  equilibrium constant and, 698
  standard molar, 697, 700
free energy of formation, 700
free radical(s) A neutral atom or molecule containing an unpaired electron, 305, 581
  chlorine, 906
  in reaction mechanism, 548
freezing point depression, 488
  for ionic solutions, 496t
freezing point depression constant (K_{fp}), 488
frequency (n) The number of complete waves passing a point in a given amount of time, 220
  relation to energy of radiation, 222
frequency factor, in Arrhenius equation, 533
Friedel–Crafts reaction, 626
Frisch, Otto, 996
frontalin, 901
fructose, 953
fuel, biological sources of, 787–789
  density of, 40
  ethanol as, 212
  fossil, 778–784
    environmental impact of, 789–796
  hydrogen as, 678, 786
  methanol as, 145
  propane as, 786
fuel cell A voltaic cell in which reactants are continuously added, 732, 784
fugu, 584
Fukushima, 997
Fuller, R. Buckminster, 59
functional group A structural fragment found in all members of a class of compounds, 917
fusion The state change from solid to liquid, 189
  enthalpy of, 460, 461t, A-14t
  heat of, 189
  nuclear, 998

galena, 665
gallium, abundance of, 822
  melting point of, 59
gallium arsenide, 456, 839
Galvani, Luigi, 714
galvanic cell(s), 714
gamma ray(s) High-energy electromagnetic radiation, 220, 976
  from matter-antimatter annihilation, 1001
gangue A mixture of sand and clay in which a desired mineral is usually found, 864
gas(es) The phase of matter in which a substance has no definite shape and a volume defined only by the size of its container, 6
  compressibility of, 374
  density, calculation from ideal gas law, 383
  diffusion of, 396, 685
  dissolution in liquids, 479
  expansion as spontaneous process, 681
  greenhouse, 394, 791
  ideal, 382
  in atmosphere, 764t
  in equilibrium constant expression, 560, 567
  kinetic-molecular theory of, 390–396, 406
  laws governing, 374–381, 395
  mixtures of, partial pressures in, 387–390
  natural, 778
  noble. *See* noble gas(es).
  nonideal, 399
  pressure of, 372
  properties of, 370–403
  solubility in water, 417t
  speeds of molecules in, 391
  standard molar volume, 382
  volume effects on equilibria of, 577
gas chromatography, 432
gas constant (*R*) The proportionality constant in the ideal gas law, 0.082057 L·atm/mol·K or 8.314510 J/mol·K, 382, A-13t
  in Arrhenius equation, 533
  in equilibrium constant expression, 560
  in kinetic energy–temperature relation, 393
  in Nernst equation, 744
  in nonequilibrium free energy change, 698
  in osmotic pressure equation, 491
gas-forming reaction(s), 123, 133
gasification, coal, 781
gasoline, energy per kilogram, 733t
  production of, 785
Gay-Lussac, Joseph, 380
GC-MS. *See* gas chromatograph *and* mass spectrometers
gecko, wall-climbing ability of, 404
Geiger, Hans, 55
Geiger-Müller counter, 989
Geim, Andre, 458
gel A colloidal dispersion with a structure that prevents it from flowing, 498
gemstones, colors of, 248, 859
  solubility of, 658
general gas law An equation that allows calculation of pressure, temperature, and volume when a given amount of gas undergoes a change in conditions, 378
genetic code, 960
geometric isomers Isomers in which the atoms of the molecule are arranged in different geometric relationships, 878, 899
  of alkenes, 908
Gerlach, Walther, 243
germanium, 57
  abundance of, 827
  as semiconductor, 455
  compounds of, 827
Germer, L. H., 234
Gibbs, J. Willard, 696
Gibbs free energy (*G*) A thermodynamic state function relating enthalpy, temperature, and entropy, 696–708
  cell potential and, 748
  work and, 699
gigaton, 765
Gimli Glider, 40
glacial acetic acid, 627
glass, colors of, 859
  etching by hydrogen fluoride, 849
  structure of, 460
glass electrode, 747
glassware, laboratory, 14, 27, 157
  laboratory, significant figures and, 35
global warming, 769
glucose, combustion of, stoichiometry of, 141
  metabolism of, 970
  oxidation in respiration, 968
  structure and isomers of, 953–954
glue, chemistry of, 940
glutamic acid, structure of, 947
glutamine, structure of, 947
glycerol, 789, 798, 918
glycine, adhesive based on, 940
  Lewis structure of, 295t
  structure of, 947
glycogen, 955, 956
glycolysis, 706
glycosidic bond, 954
goethite, 667
goiter, 848, 849
gold, as bacteriocide, 799
  density of, 14
  extraction from ore, 674
  reaction with aqua regia, 837
  uses of, 1
Gomberg, Moses, 581
Goodyear, Charles, 935
Goodyear blimp, 401
gout, lead poisoning and, 833
Graham, Thomas, 397, 498
Graham's law, 397
gram (g), 27
graph(s), analysis of, 39
graphene, 458
  pi bonds in, 365
graphite, structure of, 59, 60, 457

graphite electrode, 726
  oxidation of, 755
gravitational energy The energy due to the attraction between masses, 17
gray The SI unit of radiation dosage, 998
green chemistry, 796–800
  atom economy and, 150
  catalysts, 893
  of adhesives, 940
  of cement, 831
  of dyes and pigments, 366
  polylactic acid, 937
  principles of, 5–6, 797
  supercritical carbon dioxide and, 430
greenhouse gases, 394, 791
ground state The state of an atom in which all electrons are in the lowest possible energy levels, 228, 254
  nuclear, 978
group(s) The vertical columns in the periodic table of the elements, 53
  ion charge related to, 66–68
  similarities within, 804t
Group 1A elements, 58. *See also* **alkali metal(s)**.
  chemistry of, 812–817
Group 2A elements, 58. *See also* **alkaline earth metal(s)**.
  chemistry of, 817–821
Group 3A elements, 59
  chemistry of, 822–827
Group 4A elements, 59
  chemistry of, 827–833
Group 5A elements, 60
  chemistry of, 833–842
Group 6A elements, 60
  chemistry of, 842–846
Group 7A elements, 61. *See also* **halogens**.
  chemistry of, 846–851
Group 8A elements, 61. *See also* **noble gas(es)**.
  chemistry of, 851–853
guanine, 332
  hydrogen bonding to cytosine, 414, 958
  in DNA and RNA, 956, *957*
guidelines, assigning oxidation numbers, 127
  solubility of ionic compounds in water, *108*
Gummi Bear, *200*
guncotton, 214
gunpowder, 816
  combustion of, 214
gypsum, 75, 817
  ions in, 66

Haber, Fritz, 451, 579
Haber-Bosch process, 579
Hahn, Otto, 996
hair dye, hydroxyl radicals in, 306
half-cell A compartment of an electrochemical cell in which a half-reaction occurs, 723
half-life ($t_{1/2}$) The time required for the concentration of one of the reactants to reach half of its initial value, 525
  for radioactive decay, 987
half-reaction method A systematic procedure for balancing oxidation–reduction reactions, 715
half-reactions The two chemical equations into which the equation for an oxidation–reduction reaction can be divided, one representing the oxidation process and the other the reduction process, 126, 715
  sign of standard reduction potential for, 737
  standard potentials for, 737
halide ions Ions of the elements of Group 7A, 71
halides, as strong electrolytes, 106
  compounds with aluminum, 826
Hall, Charles Martin, 823
Hall-Heroult process, aluminum production by, 823
halogenation, of benzene, 915
halogens The elements in Group 7A of the periodic table, 61
  as oxidizing agents, 130t
  chemistry of, 846–851
  electron attachment enthalpies of, 273
  electron configuration of, 258
  oxidation number of, 127
  ranked by oxidizing ability, 741
  reaction with akenes and alkynes, 911
  reaction with alkali metals, 815
halothane, 389
hard water, 820
  detergents and, 501
heat, as form of energy, 182
  as reactant or product, 578
  entropy and, 683
  from combustion of hydrocarbons, 780
  sign conventions for, 185, 194t
  temperature change and, 185
  transfer, as spontaneous process, 681
    calculations, 186
    during phase change, 189
heat capacity, 185
heat of fusion The quantity of heat required to convert 1 g of a solid to a liquid at constant temperature, 189. *See also* **enthalpy of fusion**.
heat of solution. *See* **enthalpy of solution**.
heat of vaporization The quantity of heat required to convert 1 g of a liquid to a gas at constant temperature, 189. *See also* **enthalpy of vaporization**.
heat pack, supersaturated solution in, 474
heavy water, *48*
Heisenberg, Werner, 235
Heisenberg's uncertainty principle It is impossible to determine both the position and the momentum of an electron in an atom simultaneously with great certainty, 236
Heliox, 469
helium, abundance of, 852
  departure from ideal gas law, 400
  discovery of, 61, 244, 852
  electron configuration of, 256
  Henry's law constant, 480t
  in atmosphere, 765
  in balloons, 810
  in blimps, 401
  nucleus as alpha particle, 976
  orbital box diagram, 250
hematite, 667, 865
  ions in, *66*
heme unit, 872, 949
hemoglobin, 278, 872
  carbonic anhydrase and, 540
  iron in, 859
  structure of, 949
Henderson-Hasselbalch equation, 638
Henry's law The concentration of a gas dissolved in a liquid at a given temperature is directly proportional to the partial pressure of the gas above the liquid, 479
heptane, separation from hexane, 502
Herculon, 933t
Heroult, Paul, 823
hertz The unit of frequency, or cycles per second; 1 Hz = 1 s^{-1}, 220
Hertz, Heinrich, 220
Hess's law If a reaction is the sum of two or more other reactions, the enthalpy change for the overall process is the sum of the enthalpy changes for the constituent reactions, 205–211
heterogeneous mixture A mixture in which the properties in one region or sample are different from those in another region or sample, 9
heteronuclear diatomic molecule(s) A molecule composed of two atoms of different elements, 362
hexachloroethane, in fireworks, 233
hexadentate ligands, 871
hexagonal close-packed (hcp) unit cell, 442
hexamethylenediamine, 938
hexane, separation from heptane, 502
  structural isomers of, 903
hexaphenylethane, 581
hexose, 953
HFC. *See* hydrofluorocarbons.
high pressure liquid chromatograph (HPLC), *433*
high-spin configuration The electron configuration for a coordination complex with the maximum number of unpaired electrons, 886
high-density polyethylene (HDPE), 934

highest occupied molecular orbital (HOMO), 361t
Hindenburg, 810
Hippocrates, 857
hippuric acid, formula of, 87
histidine, structure of, *947*
hockey stick graph, 792
hole(s), in crystal lattice, 445
  in metallic conduction, 453
  in semiconductors, 455
homogeneous catalyst A catalyst that is in the same phase as the reaction mixture, 538
homogeneous mixture A mixture in which the properties are the same throughout, regardless of the optical resolution used to examine it, 9
homonuclear diatomic molecule(s) A molecule composed of two identical atoms, 358
  electron configurations of, 360
hormones, 964
human immunodeficiency virus (HIV), 962–963
Hund's rule The most stable arrangement of electrons in a subshell is that with the maximum number of unpaired electrons, all with the same spin direction, 257
  coordination complexes and, 885
  hybrid orbitals and, 344
  molecular orbitals and, 355
hybrid, resonance, 298
hybrid orbital(s) An orbital formed by mixing two or more atomic orbitals, 342–348
  geometries of, *343*
  in benzene, 354
hydrated compound A compound in which molecules of water are associated with ions, 75, 868
  formula unit of, 89
hydration, enthalpy of, 408
  of ions, 476
hydraulic fracturing, 779
hydrazine, 77
  formula of, 85
  production by Raschig reaction, 545, 835
  reaction with water, 835
hydrides, 810
  boron, 825
  of Group 3A elements, 822
hydrocarbon(s) A compound that contains only carbon and hydrogen, 902–917
  catalytic steam reformation of, 811
  combustion analysis of, 152–156
  derivatives of, naming of, A-17
  immiscibility in water, 474
  Lewis structures of, 294
  naming of, 77, A-15
  strained, 907
  types of, 902t
hydrochloric acid, 850. *See also* hydrogen chloride.
  reaction with ammonia, 604
  reaction with calcium carbonate, 123
  titration with sodium hydroxide, 644
hydrofluoric acid, production of, 819
hydrofluorocarbons (HFCs), 792
hydrogen, as fuel, 678, 786
  as reducing agent, 130t
  binary compounds of, 76
  bonding in, 286
  bridging, 364
  chemistry of, 809–812
  compounds of, 412
    Lewis structures of, 292
    with nitrogen, 835
  electron configuration of, 256
  fusion of, 998
  Henry's law constant, 480t
  in balloons, 810
  in fuel cell, 733, 785
  in oxoanions, 72
  ions formed by, 68
  isotopes of, 809
  line emission spectrum, *227*
    explanation of, 230–232
  molecular orbital energy level diagram, 356
  orbital box diagram, 250
  oxidation number of, 128
  potential energy during bond formation, 341
  preparation of, 811
  production by electrolysis, 787
  production by steam reforming, 787
  production by water–gas reaction, 787
  reaction with alkenes and alkynes, 912
  reaction with iodine, 567
  reaction with iodine, mechanism of, 550
  reaction with nitrogen, 386
  reaction with oxygen, 16
  transportation of, 787
hydrogen bonding Attraction between a hydrogen atom that is bonded to a very electronegative atom, and another atom to produce an unusually strong dipole–dipole attraction, 411–416
  in biochemistry, 414
  in DNA, 332, 958
  in polyamides, 938
hydrogen carbonate ion, 121
hydrogen chloride, as strong electrolyte, 107
  emitted by volcanoes, 172
  production of, 850
  reaction with 2-methylpropene, 911
  reaction with ammonia, 120, 391
  reaction with magnesium, 202
  reaction with sodium hydroxide, 119
hydrogen electrode, 726
  as pH meter, 746, *747*
  standard, 735
hydrogen fluoride, electrostatic potential map of, 324
  production of, 849
  reaction with silicon dioxide, 829, 849
  sigma bond in, 341
hydrogen halides, acid strengths of, 617
  standard enthalpies of formation of, 209t
  standard enthalpies of vaporization of, 424t
hydrogen iodide, decomposition of, 523
  equilibrium with hydrogen and iodine, 681
hydrogen ion. *See* hydronium ion.
hydrogen peroxide, catalyzed decomposition of, 513, 515
  decomposition of, 522
  in hair dye, 306
hydrogen phosphate ion, buffer solution of, 637t
  in respiration, 706
hydrogen phthalate ion, buffer solution of, 637t
hydrogen sulfide, as polyprotic acid, 588t
  properties of, 845
  reaction with manganese ions, 743
  sulfur-oxidizing bacteria and, 844
hydrogenation An addition reaction in which the reagent is molecular hydrogen, 328, 912
  of benzene, 915
hydrolysis reaction A reaction with water in which a bond to oxygen is broken, 928
  of anions of insoluble salt, 665
  of ATP to ADP, 969
  of ions in water, 598
  solubility and, 662
hydrometallurgy Recovery of metals from their ores by reactions in aqueous solution, 864, 866
hydronium ion, $H_3O^+(aq)$, 117–118
  as Lewis adduct, 623
  concentration expressed as pH, 162
  molecular geometry of, 310
hydrophilic colloids, 499
hydrophobic colloids, 499
hydroxide ion, $OH^-(aq)$, 116
  as Lewis base, 623
  formal charges in, 297
hydroxides, solubility in strong acids, 666
hydroxyapatite, 821
  in teeth, *776*
2-hydroxyethylphosphonate ion, 394
hydroxyl radical, 306
4-(*p*-hydroxyphenyl)-2-butanone, 925
hygroscopic compound A compound that absorbs water from the air, 233

hygroscopic salt, 815
hyperthyroidism, 849
hypertonic solution, 494
hypervalent compound(s) A compound in which the central atom is surrounded by more than four valence electron pairs, 303, 304t
hyperventilation, respiratory alkalosis and, 645
hypochlorite ion, 72, 775
  formal charges in, 296
  self oxidation–reduction, 542
hypochlorous acid, 850
  reaction with ammonia, 775
hypophosphoric acid, 841t
hypothesis A tentative explanation or prediction based on experimental observations, 4
hypothyroidism, 849
hypotonic solution, 494
hypoxia, 370

ibuprofen, synthesis of, 150, 331
ice, density of, 13
  hydrogen bonding in, 414
  melting of, 190
  structure of, 64, 415
ICE table, 557
  calculating K_a value from, 606
  completion of, 565, 567
  for common ion effect, 633
Icelandic spar, 817
Iceman, 1, 53
  radiochemical dating of, *991*
ideal gas A simplification of real gases in which it is assumed that there are no forces between the molecules and that the molecules occupy no volume, 382
ideal gas law A law that relates pressure, volume, number of moles, and temperature for an ideal gas, 381–385
  departures from, 399
  osmotic pressure equation and, 491
  stoichiometry and, 386
ideal solution A solution that obeys Raoult's law, 484
ilmenite, 846
imaging, medical, 1001
immiscible liquids, 474
indicator(s) A substance used to signal the equivalence point of a titration by a change in some physical property such as color, 166
  acid–base, 506, 653–655
indigo plant, 366
indium, abundance of, 822
induced dipole(s) Separation of charge in a normally nonpolar molecule, caused by the approach of a polar molecule, 416
induced dipole–induced dipole attraction The electrostatic force between two neutral molecules, both having induced dipoles, 417
inert gas(es). *See* **noble gas(es)**.
inertia, A-6
infant formula, adulteration of, 422
infrared goggles, 222
infrared (IR) radiation, 220
  in greenhouse effect, 791
initial rate The instantaneous reaction rate at the start of the reaction, 517
initiation step, in chain reaction, 549, 996
inner transition elements. *See* **actinide(s)** and **lanthanide(s)**.
insoluble compound(s), 655
  solubility product constants of, 658t
instantaneous reaction rate, 509
integrated rate equation An equation relating the concentration of a reactant to its initial concentration and the elapsed time, 520–529
  for nuclear decay, 989
integrity, in science, 5
intensive properties Physical properties that do not depend on the amount of matter present, 14
intercept, of straight-line graph, 39, 524
Intergovernmental Panel on Climate Change (IPCC), 769, 792
intermediate. *See* **reaction intermediate**.
intermolecular forces Interactions between molecules, between ions, or between molecules and ions, 399, 404–435
  between amino acids in protein, 949
  determining types of, 418
  energies of, 407, *418*
  in alcohols, 920
  solubility and, 410, 476
internal energy The sum of the potential and kinetic energies of the particles in the system, 194
internal energy change, as state function, 197
  measurement of, 203
  relation to enthalpy change, 196
International System of Units. *See* **SI**.
International Union of Pure and Applied Chemistry (IUPAC), 905, A-15
interstitial hydrides, 810
intravenous solution(s), tonicity of, 494
intrinsic semiconductor, 455
iodide ion, reaction with iron(III) ion, 565
iodine, abundance of, 846
  as catalyst, 536
  clock reaction, 513
  dissociation of, 569
  production of, 848
  reaction with hydrogen, 567
    mechanism of, 550
  reaction with sodium thiosulfate, 173
  solubility in liquids, 419
  solubility in polar and nonpolar solvents, 474
iodine-131, radioactive half-life, 988
  treatment of hyperthyroidism, 849
iodine monochloride, decomposition of, 707
iodine tetrafluoride ion, molecular geometry of, 312
ion(s) An atom or group of atoms that has lost or gained one or more electrons so that it is no longer electrically neutral, 12, 66. *See also* **anion(s)**; **cation(s)**.
  acid–base properties of, 599t
  complex. *See* coordination complex(es).
  concentrations of, 158
  direction of flow in voltaic cells, 724
  electron configurations of, 263–266
  formation by metals and nonmetals, 66–68
  hydration of, 408, 476
  in aqueous solution, 105
  monatomic, 66–68
  noble gas electron configuration in, 277–278
  polyatomic, 68
  sizes of, 274
  spectator, 112
ion exchange, in water softener, 820
ion–dipole attraction The electrostatic force between an ion and a neutral molecule that has a permanent dipole moment, 407
  solubility in water and, 476
ionic bond(s) The attraction between a positive ion and a negative ion resulting from the complete (or nearly complete) transfer of one or more electrons from one atom to another, 284, 854
ionic compound(s) A compound formed by the combination of positive and negative ions, 65–75
  as electrolytes, 106
  balancing charges in, 68–71
  colligative properties of solutions of, 495–497
  crystal cleavage, 74
  formula mass of, 81
  formulas of, 68–71
  lattice energy of, 450t
  melting point of, 460, 461t
  naming, 72
  of main group elements, 805
  properties of, 73
  solubility in water, 108, 475, 476
    temperature and, *483*
ionic radius, lattice energy and, 460
  periodicity of, 274
ionic solid(s) A solid formed by the condensation of anions and cations, 444–449

ionization constant(s) The equilibrium constant for an ionization reaction, 589
acid and base, 593, A-20, A-22
water, 589
ionization energy The energy change required to remove an electron from an atom or ion in the gas phase, 269, 270t
in photoelectron spectroscopy, 272
periodicity of, 270
values of, A-18
iridium, density of, 859
iron, biochemistry of, 278
combustion of, 213
corrosion of, 863
in meteorite, *268*
most stable isotope, 986
production of, 865
reaction with copper ions, 724
reaction with oxygen, 100
iron(III) hydroxide, formation by precipitation, 111
iron(II) ion, complexes of, 623
in hemoglobin, 872, 949
in jade, 437
in metal-organic framework, *762*, 763
in sapphire, 249
oxidation by bacteria, 868
oxidation–reduction titration of, 170
reaction with permanganate ion, 130, 721
iron(III) ion, coordination complex with oxalate ion, 871
paramagnetism of, 264
reaction with iodide ion, *565*
iron(III) nitrate, dilution of, 161
iron(III) oxide, formation by corrosion, 863
reaction with carbon monoxide, *125*
reduction of, 865
iron pyrite, 11, *658*
irreversible process A process that involves nonequilibrium conditions, 682
isobutane, conversion to butane, *563*, *575*
isochron dating, 1006
isoelectronic ions Ions that have the same number of electrons but different numbers of protons, 276
isoelectronic species Molecules or ions that have the same number of valence electrons and similar Lewis structures, 294
isoflurane, 850, 852
isoleucine, structure of, *947*
isomer(s) Two or more compounds with the same molecular formula but different arrangements of atoms, 352
cis-trans. *See cis-trans* isomers.
coordination, 877
geometric, 878, 899, 908
linkage, 877
Markovnikov's rule and, 911
mer-fac, 879
number of, 903
of organic compounds, 898–900
optical, 879, 900
structural. *See* **structural isomers**.
isomerization, *cis-trans*, *536*
in petroleum refining, 785
isoprene, in rubber, 935
isopropyl alcohol, 918
isotonic solution, 494
isotope(s) Atoms with the same atomic number but different mass numbers, because of a difference in the number of neutrons, 48–50
hydrogen, 809
in mass spectra, 91
metastable, 1001
oxygen, 767
percent abundance of, 49, 51t
radioactive, as tracers, 1003
radioactive decay of, 978
separation of, 997
stable and unstable, 982
synthesis of, 993
isotope dilution, volume measurement by, 1003
isotope labeling, 928
isotope ratio, dating meteorites by, 1005
geographic variations of, 53

jade, 436
color of, *890*
jadeite, 436
jasmine, oil of, 929
JELL-O®, as colloid, 498
Joliot, Frédèric, 54
joule (J) The SI unit of energy, 27, A-7, A-11
Joule, James P., *27*, 183

K capture. *See* **electron capture**.
kaolinite clay, 830
Kekulé, August, 353, 914
kelvin (K), 25, 376, A-10
in heat calculations, 187
Kelvin, Lord (William Thomson), 25, *376*
Kelvin temperature scale A scale in which the unit is the same size as the Celsius degree but the zero point is the lowest possible temperature, 25. *See also* **absolute zero**.
kerosene, production of, 785
Ketelaar, J. A. A., 854
ketone(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to two other carbon atoms, 924, 925
naming of, A-17
reduction to secondary alcohols, 925
ketose, 953
Kevlar, structure of, 939
kidney stones, oxalic acid and, 631
kilocalorie (kcal), 27, A-8t
kilogram (kg) The SI base unit of mass, 27, A-10
kilojoule (kJ), 27
kilopascal (kPa), 372
kinetic energy The energy of a moving object, dependent on its mass and velocity, 7, 17
distribution in gas, 532
temperature and, 391–393
distribution in liquid, *422*
of alpha and beta particles, 977
total, 391
kinetic stability, of organic compounds, 901
kinetic-molecular theory A theory of the behavior of matter at the molecular level, 7
departures from assumptions of, 399
gas laws and, 395
of gases, 390–396
physical states and, 406
kinetics. *See* **chemical kinetics**.
Kohlrausch, Friedrich, 589
krypton, abundance of, 852
Kynamro, 964

lactase, 955
lactic acid, 926t
acid ionization constant of, 605
ionization of, 634
optical isomers of, 900
lactose, structure of, 954
Lake Mead, 771, *772*
Lake Nyos, 482
lakes, freezing of, 415
lanthanide(s) The series of elements between lanthanum and hafnium in the periodic table, 62, 858
electron configurations of, 260
properties of, 279
uses of, 891
lanthanide contraction The decrease in ionic radius that results from the filling of the 4*f* orbitals, 862
lanthanum, in superconductors, 135
laser, synthetic ruby in, 249
lattice energy ($\Delta_{lattice}U$) The energy of formation of one mole of a solid crystalline ionic compound from ions in the gas phase, 449–452
ionic radius and, 460
relation to solubility, 477
lattice enthalpy ($\Delta_{lattice}H$) The enthalpy of formation of one mole of a solid crystalline ionic compound from ions in the gas phase, 450

lattice point(s) The corners of the unit cell in a crystal lattice, 438
laughing gas, 835
Lavoisier, Antoine Laurent, 46, 98–99
law A concise verbal or mathematical statement of a relation that is always the same under the same conditions, 4
  Beer-Lambert, 175
  Boyle's, 374
  Charles's, 376
  conservation, of energy, 18, 182
    of mass, 4
    of matter, 98
  Coulomb's, 73, 407
  Dalton's, 387
  general gas, 378
  Graham's, 397
  Henry's, 479
  Hess's, 205–211
  ideal gas, 381–385
  of chemical periodicity, 57
  of constant composition, 12
  of definite proportions, 12
  of thermodynamics, first, 193–198, 680
    second, 682
    third, 687
  Raoult's, 484
  rate. *See* **rate equation(s)**.
Le Chatelier's principle A change in any of the factors determining an equilibrium will cause the system to adjust to reduce the effect of the change, 481, 575
  common ion effect and, 633
lead, abundance of, 827
  density of, 13
  end of radioactive series, 978
  isotope ratios, 53
  pollution by, 775, 833
lead(II) chloride, solubility of, 662
lead(II) chromate, *656*
  formation by precipitation, 111
lead(II) iodide, dissolution of, *699*
lead(IV) oxide, in lead storage battery, 731
lead storage battery, 731
lead(II) sulfide, formation by precipitation, 111
  roasting of, 845
  solubility of, 665
least-squares analysis, 41
lecithin, 500
Leclanché, Georges, 730
Lego bricks, ABS plastic in, 936
lemon juice, pH of, 163
length, common units of, A-12
  measurement of, 25
leucine, structure of, *947*
leveling effect, 627
levo enantiomer, 923
Lewis, Gilbert Newton, 285, 622
Lewis acid(s) A substance that can accept a pair of electrons to form a new bond, 622–627
  molecular, 624
Lewis base(s) A substance that can donate a pair of electrons to form a new bond, 622–627
  ligands as, 870
  molecular, 626
Lewis electron dot symbol/structure(s) A notation for the electron configuration of an atom or molecule, 285–295
  predicting, 292–295
  procedure for constructing, 287
Li, Kaichang, 940
Libby, Willard, 991
life, chemistry of, 944–973
ligand(s) The molecules or anions bonded to the central metal atom in a coordination compound, 671, 870
  as Lewis bases, 870
  naming of, 874
  spectrochemical series of, 890–893
ligand field splitting (Δ_0) The difference in potential energy between sets of *d* orbitals in a metal atom or ion surrounded by ligands, 884
  spectrochemical series and, 890
ligand field theory A theory of metal-ligand bonding in coordination compounds, 883–888
light. *See also* **electromagnetic radiation**.
  absorption and reemission by metals, 454
  absorption by pi bonds, 366
  plane-polarized, 879, 900
  scattering by colloids, 498
  speed of, 220, 985, A-13t
  visible, 220, 888
light-emitting diode (LED), 456, 779
lignin, oxidation of, 893
lignite, 781
lime, 819
  in water softener, 820
  reaction with water, 122
  slaked, 821
limestone, 817
  dissolving in vinegar, *123*
  in iron production, 865
  in stalactites and stalagmites, 102
limiting reactant The reactant present in limited supply that determines the amount of product formed, 143
line emission spectrum The spectrum of light emitted by excited atoms in the gas phase, consisting of discrete wavelengths, 226
linear electron-pair geometry, orbital hybridization and, *343*, 347
linear molecular geometry, 307–313, 876
  in carbon compounds, 898
linear regression analysis, 41
linkage isomers Two or more complexes in which a ligand is attached to the metal atom through different atoms, 877
linoleic acid, 798
lipid(s) Any of a class of biological compounds that are poorly soluble in water but soluble in organic solvents, 964–968
liquefaction, coal, 781
liquid(s) The phase of matter in which a substance has no definite shape but a definite volume, 6
  miscible and immiscible, 474
  properties of, 421–432
liter (L) A unit of volume convenient for laboratory use; 1 L = 1000 cm^3, 27
lithium, abundance of, 812
  bands of molecular orbitals in, *453*
  effective nuclear charge in, 253
  electron configuration of, 256
  reaction with water, 386
  transmutation to helium, 994
  uses of, 445
lithium aluminum hydride, as reducing catalyst, 925
lithium carbonate, 817
lithium-ion battery, 445, 712, 732
lithium-ion polymer battery, 732
litmus, 162, *163*
livermorium, 993
Lockyer, Sir Joseph Norman, 244
logarithms, 162, A-2
London dispersion forces, 418
lone pair(s) Pairs of valence electrons that do not contribute to bonding in a covalent molecule, 286
  effect on electron-pair geometry, 309
  in formal charge equation, 296
  in Lewis base, 623
  in ligands, 870
  valence bond theory and, 342
low-spin configuration The electron configuration for a coordination complex with the minimum number of unpaired electrons, 886
low-density polyethylene (LDPE), 934
lowest unoccupied molecular orbital (LUMO), 361t
Lowry, Thomas M., 116
Lucite, 933t
lycopodium powder, *514*
Lyman series, 231
lysine, structure of, *947*
lysozyme, 951

Macintosh, Charles, 935
macroscopic level Processes and properties on a scale large enough to be observed directly, 7
magic numbers, of protons and neutrons, 993
magnesite, 817
magnesium, abundance of, 817
  chemistry of, 818
  combustion of, 125, 127
  in chlorophyll, 821

production of, 818
reaction with hydrogen chloride, 202
reaction with nitrogen, 834
reduction of silicon by, 828
salts of, in fireworks, 233
magnesium carbonate, in magnesite, 817
magnesium chloride, electrolysis of, 818
in table salt, 815
magnesium fluoride, solubility of, 660
magnesium hydroxide, precipitation of, 668
magnesium oxide, crystal structure of, 449
magnesium perchlorate, water absorption by, 153
magnesium silicates, reaction with carbon dioxide, 831
magnetic quantum number, 237
magnetic resonance imaging (MRI), helium and, 62, 852
magnetism. *See also* **diamagnetism**, **paramagnetism**.
in high-spin and low-spin complexes, 886
magnetite, 863
main group element(s), 53, *56*
atomic radii, *268*
chemistry of, 802–855
electron configurations, 256–258
ionic compounds of, 805
ionization energies, 271
molecular compounds of, 806
malachite, 22, *656*, *864*
malic acid, *615*, 926t
malleability, metallic, 454
manganese, oxidation–reduction cycle in sea water, 743
manganese(II) carbonate, *656*
manganese(II) dioxide, in dry cell battery, 730
mannitol, 797
manometer, U-tube, 373
mantissa The part of a logarithm to the right of the decimal point, A-3
Markovnikov, Vladimir, 911
Markovnikov's rule, 911
Marsden, Ernest, 55
martensite, unit cell of, 867
mass A measure of the quantity of matter in a body, 27
conservation of, 715, 977
energy equivalence of, 985
in stoichiometry, 138–143
law of conservation of, 4
units of, A-12
weight and, A-6
mass balance, 139
mass defect, 49, 985
mass number (*A*) The sum of the number of protons and neutrons in the nucleus of an atom of an element, 47
in nuclear symbol, 977
mass percent. *See* **percent composition**.
mass spectrometer, 49
determining formula with, 91
matches, phosphorus sulfide in, 839
matter Anything that has mass and occupies space, 6, A-6
classification of, 6–10
dispersal of, 685
law of conservation of, 98
states of, 6, 406
matter wave, 234
matter-antimatter annihilation, 1001
mauveine, 366
Maxwell, James Clerk, 220, 391
Maxwell-Boltzmann distribution curves, 391, 532, 686
McMillan, Edwin, *992*
mean square speed, of gas molecules, 393
measured quantity, significant figures in, 35
measurement(s), units of, 23–28, 372, A-10
mechanical energy The energy due to the motion of macroscopic objects, 17
mechanism, reaction. *See* **reaction mechanism**.
Meitner, Lise, *996*
melamine, pet food adulterated with, 422
melting point The temperature at which the crystal lattice of a solid collapses and solid is converted to liquid, 460, 461t, A-14t
identifying compounds by, 14
of ionic solids, 73
of transition elements, 862
membrane, biological cell, *966*
ion-permeable, 724
proton exchange, 733
semipermeable, 489
membrane cell, *816*
chlorine production by, 847
Mendeleev, Dmitri Ivanovitch, *57*
meniscus, 430
Menten, Maud L., 540
mercury, coal power and, 781
from cinnabar, *3*
in pressure measurement, 372
line emission spectrum, *227*
melting point of, 859
poisoning symptoms, *775*
mercury battery, 730
mercury electrode, 726
mercury(II) oxide, decomposition of, 99
mer-fac isomers, 879
messenger RNA (mRNA), 959
meta position, 914
metabolic alkalosis and acidosis, 645
metabolism The entire set of chemical reactions that take place in the body, 968–971
metal(s) An element characterized by a tendency to give up electrons and by good thermal and electrical conductivity, 53, *56*, 58
as reducing agents, 130t
biochemistry of, 278
bonding in, band theory of, 452
cations formed by, 66
acid–base properties of, *599*
coinage, 22
coordination compounds of, 868
electronegativity of, 315
enthalpy of fusion of, *461*
hydrated cations as Brønsted acids, 587, 622
melting point of, 461t
plating by electrolysis, 751
reaction with hydrogen chloride, 850
sulfides, in black smokers, *96*
solubility product constants of, A-24
transition. *See* transition elements.
unit cell types of, 439, *440*
water pollution by, 774
metal hydrides, reaction with water, 812
metallic bond(s), 284, 854
metallic character, periodicity of, 805
metalloid(s) An element with properties of both metals and nonmetals, 53, *56*, 58
electronegativity of, 315
metallurgy, 864–868
metal-organic framework (MOF), 762
metaphosphoric acid, 841t
metastable isotope, 1001
metathesis reaction(s). *See* **exchange reaction(s)**.
meteorite, iron, *268*
meteorites, determining ages of, 1005
meter (m) The SI base unit of length, 25, A-10
methane, as fuel, 782
as greenhouse gas, 771, 791
atmospheric, sources of, 394
bond angles in, *310*
bond order in, 326
combustion analysis of, 153
standard free energy change, 701
enthalpy of formation, 207
Henry's law constant, 480t
hybrid orbitals in, 342–345
hydrogen produced from, 811
in atmosphere, 769
molar mass of, 81
reaction with chlorine, 548
standard free energy of formation of, 700
structure of, *65*
methane hydrates, 769, 782, 783

methanol, 917
as fuel, 145
hydrogen bonding in, 420
in denitrification, 838
in fuel cell, 785
Lewis structure of, 295t
orbital hybridization in, 345
reaction with carbon monoxide, 926
reaction with halide ions, 538
spontaneity of formation reaction, 692
synthesis of, 145
methicillin-resistant *Staphylococcus aureus* (MRSA), 857
methionine, structure of, *947*
methoxyethyl group, 964
methyl alcohol. *See* methanol.
methyl chloride, reaction with halide ions, 538
methyl ethyl ketone, 925t
methyl mercaptan, 845
methyl methacrylate, synthesis of, 150
methyl salicylate, 493, 929
N-methylacetamide, structure of, 930
methylamine, 346
as weak base, 596
electrostatic potential map of, 324
Lewis structure of, 295t
methylamines, 921
2-methyl-1,3-butadiene. *See* isoprene.
2-methylbutane, structure of, 903
3-methylbutyl acetate, 928t
methylpentane, structural isomers of, 904
methylphosphonate ion, 394
2-methylpropane, structure of, 903
2-methylpropene, reaction with hydrogen chloride, 911
structure of, 899, 908
methylsiloxane, 832
metric system A decimal system for recording and reporting measurements, in which all units are expressed as powers of 10 times some basic unit, 23
metric ton, 765
mica, structure of, 830
Michaelis, Leonor, 540
microbial burden (MB), 857
microstates, 684
microwave radiation, 220
Midgley, Thomas, 768
milk, adulteration of, 422
milligram (mg), 27
Millikan, Robert, *55*
milliliter (mL) A unit of volume equivalent to one thousandth of a liter; 1 mL = 1 cm^3, 27
millimeter of mercury (mm Hg) A common unit of pressure, defined as the pressure that can support a 1-millimeter column of mercury; 760 mm Hg = 1 atm, 372, A-7t
mineral oil, density of, 42
minerals, analysis of, 152
clay, 830
silicate, 829
solubility of, 658
miscible liquids, 474
mixture(s) A combination of two or more substances that can be separated by physical techniques, 8–10
analysis of, 150–156
gaseous, partial pressures in, 387–390
separation by chromatography, 432
mobile phase, in chromatography, 432
models, molecular, *12,* 64
moderator, nuclear, 975
Mohr method, 172
Moisson, Henri, 847
molal boiling point elevation constant (K_{bp}), 486
molality (m) The number of moles of solute per kilogram of solvent, 471
molar absorptivity, 175
molar enthalpy of vaporization ($\Delta_{vap}H°$), relation to molar enthalpy of condensation, 423
molar heat capacity The quantity of heat required to raise the temperature of 1.00 mol of a substance by 1.00 kelvin, 185
values of, A-14t
molar mass (*M*) The mass in grams of one mole of particles of any substance, 78
calculation from colligative properties, 493
calculation from ideal gas law, 384
determination by titration, 169
effusion rate and, 397
enthalpy of vaporization and, 423
melting point and, 460
molecular speed and, 393
polarizability and, 416
molar volume, standard, 382
molarity (M) The number of moles of solute per liter of solution, 156, 471
mole (mol) The SI base unit for amount of substance, 78, A-10
conversion to mass units, 79
of reaction, 148, 198
mole fraction (*X*) The ratio of the number of moles of one substance to the total number of moles in a mixture of substances, 388, 471
in Raoult's law, 484
molecular compound(s) A compound formed by the combination of atoms without significant ionic character, 65, 76. *See also* **covalent compound(s)**.
as Brønsted acids and bases, 586
as Lewis acids, 626
as nonelectrolytes, 107
hydrogen in, 810
of main group elements, 806
molecular formula A written formula that expresses the number of atoms of each type within one molecule of a compound, 63, 900
determining, 84–92
relation to empirical formula, 87
molecular geometry The arrangement in space of the central atom and the atoms directly attached to it, 309
coordination number and, 876
hybrid orbitals and, 343
ligand field splitting and, 884
molecular polarity and, 320–325, 336t
multiple bonds and, 313
molecular mass, average, 81
molecular models, *12,* 64
molecular orbital(s), bonding and antibonding, 355
from atomic *p* orbitals, 359, 361
highest occupied (HOMO), 361t
lowest unoccupied (LUMO), 361t
photoelectron spectroscopy and, 367
molecular orbital theory A model of bonding in which pure atomic orbitals combine to produce molecular orbitals that are delocalized over two or more atoms, 340, 354–365, 883
for metals and semiconductors, 452–456
resonance and, 362–365
molecular polarity, 320–325, 336t
intermolecular forces and, 407–416
miscibility and, 474
of lipids, 965
of surfactants, 500
molecular solid(s) A solid formed by the condensation of covalently bonded molecules, 456
melting point of, 461t
solubilities of, 474
molecular structure, acid-base properties and, 617–622
bonding and, 282–335
entropy and, 688
VSEPR model of, 307–314
molecular weight. *See* **molar mass**.
molecularity The number of particles colliding in an elementary step, 541
reaction order and, 541
molecule(s) The smallest unit of a compound that retains the composition and properties of that compound, 12, 63
calculating mass of, 84
collisions of, reaction rate and, 530–538
nonpolar, interactions of, 416–419
polar, interactions of, 409
polarity of, 320
shapes of, 307–314
speeds in gases, 391
volume of, 399
molybdenite, 861
molybdenum-99, generation of technetium-99m from, 1002

monatomic ion(s) An ion consisting of one atom bearing an electric charge, 66–68
naming, 71
oxidation numbers in, 127
sizes of, 274
monodentate ligands, 870
monolayer, formation on solid surface, 398
monomer(s) The small units from which a polymer is constructed, 932
monoprotic acid(s) A Brønsted acid that can donate one proton, 587
monosaccharides, 953
moon, rock sample analysis, 1004
mortar, lime in, 819
Moseley, Henry G. J., 57
Müller, Karl, 135
Mulliken, Robert S., 334, 340
Mullis, Kary, 972
multiple bonds, bond length of, 327t
in resonance structures, 298
Lewis electron dot structure of, 289
molecular geometry and, 313
valence bond theory of, 349–353
mummy, 1
muscovite, 830
mussels, glue from, 940
mutation, of retroviruses, 963
Mylar, 937
myoglobin, 872
iron in, 859

naming, of alcohols, A-17
of aldehydes and ketones, 925t, 926, A-17
of alkanes, 902t, 905, A-15
of alkenes, 908, A-16
of alkynes, 910t, A-16
of anions and cations, 71
of aromatic compounds, A-17
of benzene derivatives, A-17
of binary nonmetal compounds, 77
of carboxylic acids, 926, 927, A-17
of coordination compounds, 874
of esters, 928, A-17
of ionic compounds, 72
of substituted alkanes, 911
nanometer, 26
nanotechnology, 24
nanotubes, carbon, 458
naphthalene, melting point of, *15*
structure of, 913
narcosis, nitrogen, 468
National Ambient Air Quality Standards (NAAQS), 790
National Institute of Standards and Technology (NIST), 29, 209
natural gas, 782
as energy resource, 778
helium in, 852
hydrogen production from, 787
natural logarithms, A-2
neodymium, in permanent magnets, 279
magnetism of, 62
neon, abundance of, 852
electron configuration of, 258
line emission spectrum of, *227*
mass spectrum of, *49*
nephrite, 436
neptunium, 993, *995*
Nernst, Walther, 744
Nernst equation An equation that relates the potential of an electrochemical cell to the concentrations of the cell reactants and products, 744
Nestlé, Henri, 896
net ionic equation(s) A chemical equation involving only those substances undergoing chemical changes in the course of the reaction, 112
of oxidation–reduction reaction, 716
of strong acid–strong base reactions, 119, 603
network solid(s) A solid composed of a network of covalently bonded atoms, 457
bonding in, 454
silicon dioxide, 828
solubilities of, 475
neurotransmitter, 923
neutral buoyancy, 401
neutral solution A solution in which the concentrations of hydronium ion and hydroxide ion are equal, 590
pH of, 162
neutralization reaction(s) An acid–base reaction that produces a neutral solution of a salt and water, 120, 604
neutrino(s) A massless, chargeless particle emitted by some nuclear reactions, 981
neutron(s) An electrically neutral subatomic particle found in the nucleus, 45
bombardment with, 993
conversion to electron and proton, 977
demonstration of, *55*
discovery of, 994
in nuclear fission reaction, 996
in nuclear reactor, 975
nuclear stability and, 983
neutron activation analysis, 1004
neutron capture reactions, 994
newton (N) The SI unit of force; $1\ N = 1\ kg \cdot m/s^2$, 372, A-7, A-11
nickel, as catalyst in diamond synthesis, 709
coordination complex with ammonia, 870
coordination complexes of, 887
nickel(II) carbonate, precipitation of, *667*
reaction with sulfuric acid, 124
nickel carbonyl, decomposition of, temperature and spontaneity, 704
nickel(II) chloride hexahydrate, 868, *869*
nickel(II) complexes, solubility of, *671*
nickel(II) ion, light absorption by, 173
nickel(II) sulfide, precipitation of, *667*
nickel-cadmium (Ni-cad) battery, 731
nickel-metal hydride battery, 712, 732
nicotinamide adenine dinucleotide (NADH), 970
nicotine, structure of, 922
night vision goggles, 222
nitrate ion, concentration in aquarium, 838
Lewis structure of, 293
molecular geometry of, 314
resonance structures of, 299, 620
nitration, of benzene, 915
nitric acid, air pollution by, 790
as oxidizing agent, 130t
Lewis structure of, 293
manufacture of, 144
pH of, 163
production by Ostwald process, 837
reaction with aluminum, 826
reaction with sodium hydroxide, 120
strength of, 618
nitric oxide. *See* nitrogen monoxide.
nitride(s), 834
nitrification, by bacteria, 838
nitrite ion, concentration in aquarium, 838
linkage isomers containing, 877
resonance structures of, 301
nitrito complex, 877
nitro complex, 877
nitrocellulose, 214
nitrogen, abundance of, 834
bond enthalpy of triple bond, 834
bond order in, 326
chemistry of, 835–838
compounds of, hydrogen bonding in, 412
with hydrogen, 835
electron configuration of, 257
fixation of, 60
Henry's law constant, 480t
in testing food for protein content, 422
Lewis structures involving, 292
liquid, 376, 834
liquid and gas volumes, *406*
molecular orbital configuration of, 360
oxidation numbers of, 835
oxides and oxoacids of, 835
reaction with hydrogen, 386
reaction with oxygen, 570, 578
solubility in blood, 468
transmutation to oxygen, 994
nitrogen cycle, 765
nitrogen dioxide, 765, 836
air pollution by, 790
dimerization of, 306, 563, 578, 836
free radical, 305
in formation of atmospheric ozone, 767
reaction with carbon monoxide, 518, 531, 545
reaction with fluorine, 544
reaction with water, 122

nitrogen monoxide, 765, 835
air pollution by, 790
free radical, 305
reaction with bromine, 539
reaction with chlorine, 516
reaction with oxygen, mechanism of, 546
reaction with oxygen, standard entropy change of, 690
reaction with ozone, 561
nitrogen narcosis, 468
nitrogen oxides, in atmosphere, 765
nitrogen trifluoride, Lewis structure of, 293
molecular polarity of, 323
nitrogenase, metals in, 859
nitrogenous base(s), 956, *957*
nitroglycerin, *919*
decomposition of, 210
in smokeless gunpowder, 214
nitronium ion, Lewis electron dot structure of, 291
nitrous acid, 836
strength of, 618
nitrous oxide. *See* dinitrogen oxide.
nitrox, 469
Nobel, Alfred, *919*
noble gas(es) The elements in Group 8A of the periodic table, 61
noble gas(es), compounds of, 304, 338, 851–853
discovery of, 92
electron configuration of, 68, 258, 278, 285, 805
ionization energies and, 277–278
in atmosphere, 765
noble gas notation An abbreviated form of *spdf* notation that replaces the completed electron shells with the symbol of the corresponding noble gas in brackets, 256
nodal surface A surface on which there is zero probability of finding an electron, 241–243
node(s) A point of zero amplitude of a wave, *220*
nonaqueous solvents, acid strength in, 627
nonbonding electrons. *See* **lone pair(s)**.
nonelectrolyte A substance that dissolves in water to form an electrically nonconducting solution, 107
nonequilibrium conditions, reaction quotient at, 562, 744
nonideal gas, 399
nonideal solution, 484
nonmetal(s) An element characterized by a lack of metallic properties, 53, *56,* 58
anions formed by, 67
binary compounds of, 77
electronegativity of, 315
nonpolar covalent bond A covalent bond in which there is equal sharing of the bonding electron pair, 314
nonpolar molecules, 322
interactions of, 416–419
nonrenewable resources, 778
nonspontaneous reaction, 680. *See also* **reactant-favored reaction(s)**.
normal boiling point The boiling point when the external pressure is 1 atm, 428
for common compounds, 424t
northwest–southeast rule A product-favored reaction involves a reducing agent below and to the right of the oxidizing agent in the table of standard reduction potentials, 739
Novoselov, Kostya, 458
n-type semiconductor, 456
nuclear binding energy, 984–987
nuclear charge, effective, 252, 253t, 262
nuclear chemistry, 974–1007
applications of, 1001–1006
nuclear energy, 996
nuclear fission, 996
nuclear fusion, 998
nuclear medicine, 1001
nuclear power generation, 778
nuclear reaction(s) A reaction involving one or more atomic nuclei, resulting in a change in the identities of the isotopes, 977–981
artificial, 992–995
predicting types of, 983
rates of, 987–992
nuclear reactor A container in which a controlled nuclear reaction occurs, 996–997
natural, 974
nucleic acid(s) A class of polymers, including RNA and DNA, that are the genetic material of cells, 956–963
nucleon A nuclear particle, either a neutron or a proton, 985
nucleoside, 956
nucleotide, 956
nucleus The core of an atom, made up of protons and neutrons, 46
size of, *55*
stability of, 982–987
Nutrient Data Laboratory website, 28
nutrition label, energy content on, 28
nylon-6,6, 938

ocean, acidification of, 792
octadecane, 433
octahedral electron-pair geometry, orbital hybridization and, 348
octahedral holes, 446
octahedral molecular geometry, 307, 308, 876
optical isomerism and, 881
octane, combustion of, 100
heat of combustion, 204
octet, of electrons, 286, 898
octet rule When forming bonds, atoms of main group elements gain, lose, or share electrons to achieve a stable configuration having eight valence electrons, 286
exceptions to, 287, 302–306, 581
odd-electron compounds, 305, 835
oil(s), as lipids, 965
reaction with methanol, 789
soaps and, 500
oil sands, 783
oil spill, cleaning, 796
Oklo, natural nuclear reactor at, 974
Olah, George, *627*
oleic acid, 926t
olivine, 829
omega-3-fatty acids, 931
optical isomers Isomers that are nonsuperimposable mirror images of each other, 879, 900
orbital(s) The matter wave for an allowed energy state of an electron in an atom or molecule, 237
atomic. *See* **atomic orbital(s)**.
molecular. *See* **molecular orbital(s)**.
orbital box diagram A notation for the electron configuration of an atom in which each orbital is shown as a box and the number and spin direction of the electrons are shown by arrows, 250
orbital hybridization The combination of atomic orbitals to form a set of equivalent hybrid orbitals that minimize electron-pair repulsions, 342–348
of nitrogen in amides, 929
orbital overlap Partial occupation of the same region of space by orbitals from two atoms, 340
order, bond. *See* **bond order**.
reaction. *See* **reaction order**.
ore(s) A sample of matter containing a desired mineral or element, usually with large quantities of impurities, 864
insoluble salts in, 667
organic compounds, bonding in, 896–943
Lewis structures of, 295
naming of, 902t, 905, A-15
stability of, 901
orientation of reactants, effect on reaction rate, 532, 538
Orlon, 933t
orpiment, 90, 658
ions in, *66*
ortho position, 914
orthophosphoric acid, 841t
orthorhombic sulfur, 843
orthosilicates, 829
osmium, density of, 859
osmosis The movement of solvent molecules through a semipermeable membrane from a region of lower solute concentration to a region of higher solute concentration, 489
reverse, 492, 774

osmotic pressure (P) The pressure exerted by osmosis in a solution system at equilibrium, 491
Ostwald, Friedrich Wilhelm, 78
Ostwald process, 837
Ötzi the Iceman, 1–2, 53, *991*
outgassing, 398
overlap, orbital, 340
overvoltage, 755
oxalate ion, as ligand (ox), 870
oxalic acid, 926t
  as polyprotic acid, 588t
  in rhubarb, 630
  molar mass of, 83, 84
  structure of, *115*
  titration of, 166, 650
oxidation The loss of electrons by an atom, ion, or molecule, 126
  at anode of electrochemical cell, 723
  half-reaction for, 715
  of transition metals, 860
oxidation number(s) A number assigned to each element in a compound in order to keep track of the electrons during a reaction, 127–129
  formal charges and, 297
  in redox reaction, 715
  of Group 3A elements, 822
  of Group 4A elements, 827
  of Group 5A elements, 833
  of transition elements, 860, *861*
oxidation reaction(s), green catalysts for, 893
  of alcohols, 924
  of organic compounds, 901
oxidation–reduction reaction(s) A reaction involving the transfer of one or more electrons from one species to another, 125–131, 712–761
  balancing equations for, 715–722
  biological, 970
  in acidic and basic solutions, 718–722
  recognizing, 129–131
  titration using, 170
oxides, as acids and bases, 121
oxidizing agent(s) The substance that accepts electrons and is reduced in an oxidation–reduction reaction, 125–126, 715
  relative strengths of, 737, 740–742
oxoacid(s), acid strengths of, 618
  Lewis structures of, 293
  of chlorine, 850
  of nitrogen, 835
  of phosphorus, 840
oxoanion(s) Polyatomic anions containing oxygen, 71
  as Brønsted bases, 622
  Lewis structures of, 293
oxy-acetylene torch, *910*
oxygen, abundance of, 843
  allotropes of, 61, 843
  as oxidizing agent, 125, 130t
  compounds of, hydrogen bonding in, 412
    with nitrogen, 835
    with phosphorus, 839
  corrosion and, 863
  deprivation and sickness, 370
  discovery of, 99
  dissolving in water, 416
  electron configuration of, 258
  from photosynthesis, 843
  Henry's law constant, 480t
  in atmosphere, 766
  in fuel cell, 733, 785
  in iron and steel production, 865–866
  isotope ratios, 53
  Lewis structures involving, 292
  molecular orbital configuration of, 360
  oxidation number of, 127
  paramagnetism of, 355, 360
  partial pressure and altitude, 392
  reaction with alkali metals, 815
  reaction with alkanes, 906
  reaction with hemoglobin, 872
  reaction with hydrogen, 16
  reaction with nitrogen, 570, 578
  reaction with nitrogen monoxide, mechanism of, 546
  reaction with sulfur, 63
  toxicity of, 469
oxygen-15, in PET imaging, 1002
oxyhemoglobin, 872
ozone, 61, 843
  as disinfectant, 773
  decomposition of, mechanism, 541
  depletion in stratosphere, 768
  fractional bond order of, 326
  in atmosphere, 767–769
  molecular orbital configuration of, 363
  reaction with nitrogen monoxide, 562
  resonance structures of, 298
  solar radiation absorbed by, 392

p orbital(s). *See* **atomic orbital(s)**.
packing, in crystal lattice, 442
paint, bactericidal, 798
  transition metal pigments in, 859
  white lead in, 833
pairing energy The additional potential energy due to the electrostatic repulsion between two electrons in the same orbital, 886
palladium, coordination complexes of, 887
  in catalytic converter, 790
para position, 914
paramagnetism The physical property of being attracted by a magnetic field, 264, *265*, 360, 886
  of transition metal ions, 860
parent ion, in mass spectra, *91*
Parkinson's disease, 923
partial charge(s) The charge on an atom in a molecule or ion calculated by assuming sharing of the bonding electrons proportional to the electronegativity of the atom, 315
partial pressure(s) The pressure exerted by one gas in a mixture of gases, 387
  in equilibrium constant expression, 560, *567*
particle accelerator, 994
particulate level Representations of chemical phenomena in terms of atoms and molecules; also called submicroscopic level, 8
partition chromatography, 433
parts per million (ppm), 472
pascal (Pa) The SI unit of pressure; 1 Pa = 1 N/m^2, 372, A-7, A-11
passive diffusion, through cell membrane, *967*
path length, light absorption and, 175
Pauli, Wolfgang, 250
Pauli exclusion principle No two electrons in an atom can have the same set of four quantum numbers, 250
  molecular orbitals and, 355
Pauling, Linus, and electronegativity, 315, 334
  and theory of resonance, 298
  and valence bond theory, 340
p-block elements, 257
  molecular orbitals involving, 359
pentane, structural isomers of, 903
pentanol, isomers of, 919
pentenes, isomers of, 908–909
pentose, 953
peptide bond, 948
peptide linkage, 930
percent abundance The percentage of the atoms of a natural sample of the pure element represented by a particular isotope, 49
percent composition The percentage of the mass of a compound represented by each of its constituent elements, 84
percent error The difference between the measured quantity and the accepted value, expressed as a percentage of the accepted value, 29–30
percent yield The actual yield of a chemical reaction as a percentage of its theoretical yield, 147
perchlorate ion, 72
perchlorates, 851
perchloric acid, 850
perhydroxyl ion, 306
periodic table of the elements, 10, 52–63, 804–809
  electron configurations and, *254*
  historical development of, 57
  ion charges and, 66–68
  metallic character in, 805

periodicity, of atomic orbital energies, 262
of atomic radii, 267
of chemical properties, 57, 276–280
of electron affinity, 273
of electron attachment enthalpy, 273
of electronegativity, 315, *316*
of enthalpy of fusion, *461*
of ionic radius, 274
of ionization energy, 270
periods The horizontal rows in the periodic table of the elements, 53
Perkin, William, 366
permanganate ion, as oxidizing agent, 130t
reaction with iron(II) ion, 130, 170
perovskite, crystal structure of, 447
peroxides, 815
oxidation number of oxygen in, 127
peroxyacyl nitrates (PANs), 766
peroxymonocarbonate ion, 306
perspective formula, 900
pertechnetate ion, 1002
pet food, adulteration of, 422
Peter, Daniel, 896
petroleum, 782
chemistry of, 785
pH The negative of the base-10 logarithm of the hydrogen ion concentration; a measure of acidity, 161–164, 589–592
calculating, after acid–base reaction, 612
from equilibrium constant, 607–614
polyprotic acids and bases, 615
salts, 610
weak acids, 607, 610
calculating equilibrium constant from, 606
change in, during acid–base titration, 644
common ion effect and, 632–635
in aquarium, 838
in buffer solutions, 636–643
of blood, 645
of ocean, 792
standard in biochemical reactions, 706
zwitterions and, 948
pH indicator(s), 653–655
pH meter, 162, *163*, *633*, 747
phase, of atomic orbitals, 359
of matter, 6, 406
phase change, as spontaneous process, 681
heat transfer in, 189
tin disease, 466
phase change random access memory (PRAM), 462
phase diagram A graph showing which phases of a substance exist at various temperatures and pressures, 463–465
phenanthroline, as ligand (phen), 870
phenol, structure of, 914
phenolphthalein, structure of, 507, *653*
phenyl group, stable free radical and, 581
phenylalanine, structure of, *947*
Philosopher's Stone, 841
phosgene, molecular polarity of, 322
reaction with bisphenol A, 941
phosphate ion, buffer solution of, 637t
in biological buffer system, 645
resonance structures of, 300
phosphate rock, 840, 846
phosphates, solubility in strong acids, 666
water pollution by, 774
phosphine, 77, 839
rate of decomposition of, 512
phosphodiester group, in nucleic acids, 956
phosphoenolpyruvate (PEP), 706
phospholipids, 966
phosphoric acid, as polyprotic acid, 588t, 596
reaction with acetate ion, 602
uses of, 842
phosphorothioate group, 964
phosphorous acid, 841t
phosphorus, abundance of, 834
allotropes of, 60, 834
chemistry of, 839–842
coordinate covalent bonds to, 304
discovery of, 841
hydrides of, 839
oxides of, 839
reaction with chlorine, 97, *98*, 139
reaction with oxygen, 100
removed from pig iron, 866
sulfides of, 839
phosphorus-32, as radioactive tracer, 1003
production of, 994
phosphorus oxoacids, 840
phosphorus pentachloride, decomposition of, 568
photocell, *224*
photochemical smog, 766
photoelectric effect The ejection of electrons from a metal bombarded with light of at least a minimum frequency, 218, 223
photoelectron spectroscopy, ionization energy determined by, 272
molecular orbital energy determined by, 367
photography, digital, 218
photolysis, flash, 550
photon(s) A "particle" of electromagnetic radiation having zero mass and an energy given by Planck's law, 224
photosynthesis, 766, 788, 970
phthalic acid, buffer solution of, 637t
physical change A change that involves only physical properties, 15–16
physical properties Properties of a substance that can be observed and measured without changing the composition of the substance, 13–15
temperature dependence of, 14
pi (π) bond(s) The second (and third, if present) bond in a multiple bond; results from sideways overlap of *p* atomic orbitals, 349
in benzene, 365
in ozone, 363
molecular orbital view of, 359
picometer, 26
pig iron, 865
pigments, green chemistry of, 366
transition metals in, 859
pitchblende, 54, 979
pK_a The negative of the base-10 logarithm of the acid ionization constant, 597
at midpoint of acid–base titration, 647
pH of buffer solution and, 638
planar node. *See* **atomic orbital(s)** and **nodal plane**.
Planck, Max, 222
Planck's constant (*h*) The proportionality constant that relates the frequency of radiation to its energy, 222, 228, A-13t
Planck's equation, 223
plasma A gas-like phase of matter that consists of charged particles, 998
plaster of Paris, 75
plastic(s). *See also* **polymer(s)**.
types of, 932
plastic sulfur, 843
plating, by electrolysis, 751
platinum, coordination complexes of, 887
in catalytic converter, 790
in cisplatin, 882
in oxidation of ammonia, *144*
platinum electrode, 726
platinum group metals, 862
platinum hexafluoride, as oxidizing agent, 852
Plexiglas, 933t
plotting. *See* graph(s).
plutonium, 993, 995
plutonium-239, fission of, 997
plywood, adhesives in, 940
pOH The negative of the base-10 logarithm of the hydroxide ion concentration; a measure of basicity, 591
poisoning, arsenic, 90
carbon monoxide, 872
hydrogen sulfide, 845
lead, 833
mercury, 775
methanol, 918
polar covalent bond A covalent bond in which there is unequal sharing of the bonding electron pair, 314
polarity, bond, 314–319
molecular, 320–325, 336t
intermolecular forces and, 407–416
miscibility and, 474, 920
solubility of carboxylic acids and, 927
of α-amino acids, 946, *947*

polarizability The extent to which the electron cloud of an atom or molecule can be distorted by an external electric charge, 416
polarized light, rotation by optical isomers, 879, *880,* 900, 954
polonium, 54, 61
  abundance of, 843
  from decay of uranium, 979
polyacrylonitrile, 933t
polyamide(s) A condensation polymer formed by elimination of water between two types of monomers, one with two carboxylic acid groups and the other with two amine groups, 937
polyatomic ion(s) An ion consisting of more than one atom, 68
  names and formulas of, 69t
  oxidation numbers in, 128
polycarbonate, synthesis of, 941
polydentate ligands, 870
polydimethylsiloxane, 832
polyester(s) A condensation polymer formed by elimination of water between two types of monomers, one with two carboxylic acid groups and the other with two alcohol groups, 937
  dyeing, 430
polyethylene, 932, 933t
  types of, 934
polyethylene terephthalate (PET), 937
  recycling, 938
polyisoprene, all-*cis,* 936
polylactic acid (PLA), 937
polymer(s) A large molecule composed of many smaller repeating units, usually arranged in a chain, 932–939
  addition, 932–936
  classification of, 932
  condensation, 932, 937–939
  osmotic pressure of, 491, 492
  silicone, 832
polymerase chain reaction (PCR), 972
polymethyl methacrylate, 933t
polypeptide, 948
polypropylene, 774, 933t
polyprotic acid(s) A Brønsted acid that can donate more than one proton, 587
  acid–base properties of, 598
  ionization constants of, 596
  pH of, 615
  titration of, 650
polyprotic base(s) A Brønsted base that can accept more than one proton, 587
  pH of, 615
polysaccharide(s) A polymer in which the monomers are sugar molecules, 952, 955, *956*
polystyrene, 932, 933t, 935
polytetrafluoroethylene, 933t
polyvinyl acetate (PVA), 933t, 935
polyvinyl alcohol, 935
polyvinyl chloride (PVC), 932, 933t
polyvinylidene fluoride, 774
popcorn, percent yield of, *147*
porphyrin, 872
Portland cement, 829, 831
positron(s) A nuclear particle having the same mass as an electron but a positive charge, 980
  emitters of, 1001
  predicting emission of, 983
positron emission tomography (PET), 1001
potassium, absorption by plants, 813
  abundance of, 812
  preparation of, 813
  reaction with water, *58*
  salts of, in fireworks, 233
potassium aluminum sulfate, as coagulant, 772
potassium chlorate, decomposition of, 843
  in matches, 839
potassium dichromate, 159
  oxidation of alcohol by, *924*
potassium dihydrogen phosphate, crystallization of, *483*
potassium fluoride, dissolution of, 476
  electrolysis of, 847
potassium ions, pumping in cells, 969
potassium nitrate, 816
  in gunpowder, 214
potassium perchlorate, 851
potassium permanganate, 157
  absorption spectrum of, *175*
  dissolution of, 686
  in redox titration, 170
  oxidation of alcohol by, 924
  reaction with iron(II) ion, 721
potassium superoxide, 815
  molecular orbital configuration of, 361
potential, of electrochemical cell, 734–743
potential energy The energy that results from an object's position, 17
  bond formation and, 341
  of electron in hydrogen atom, 228
potential ladder, *736*
pounds per square inch (psi), as pressure unit, 373, A-7t
power The amount of energy delivered per unit time, A-7
powers, on calculator, 34, A-4
precipitate A water-insoluble solid product of a reaction, usually of water-soluble reactants, 110
  gelatinous, 498
precipitation reaction(s) An exchange reaction that produces an insoluble salt, or precipitate, from soluble reactants, 110–114, 132, 655–666
  solubility product constant and, 667–670
precision The agreement of repeated measurements of a quantity with one another, 29
prefixes, for ligands, 875
  for organic substituent groups, 905
  for SI units, 23, 24t, A-11
pressure The force exerted on an object divided by the area over which the force is exerted, 372
  atmospheric, altitude and, 370, A-7
  constant, calorimetry at, 201
  critical, 429
  effect on solubility, 479
  gas, volume and, 374
  of atmosphere, 765
  partial. *See* **partial pressure.**
  relation to boiling point, 428
  standard, 382
  units of, 372, A-7
  vapor. *See* **vapor pressure.**
pressure–volume work, 194
Priestley, Joseph, 99
primary alcohols, 924
primary amines, 921
primary battery, 729
primary colors, 889
primary standard A pure, solid acid or base that can be accurately weighed for preparation of a titrating reagent, 168
primary structure, of protein, 949
primer, in polymerase chain reaction, 972
primitive cubic (pc) unit cell, 439
principal quantum number, 228, 237
probability, diffusion and, 685–687
  in quantum mechanics, 236
probability density The probability of finding an atomic electron within a given region of space, related to the square of the electron's wavefunction, 236, 239
problem solving strategies, 41–43
Problem Solving Tip, aqueous solutions of salts, 600
  balanced equations and equilibrium constants, 574
  balancing equations in basic solution, 723
  balancing oxidation–reduction equations, 720
  buffer solutions, 641
  calculating ΔT, 187
  choosing the central atom in a dot structure, 287
  concepts of thermodynamics, 680
  determining a rate equation, 520
  determining ionic compounds, 74
  determining strong and weak acids, 594
  drawing structural formulas, 905
  electrochemical conventions for voltaic cells and electrolysis cells, 752
  finding empirical and molecular formulas, 86
  formulas for ions and ionic compounds, 72
  ligand field theory, 887

Problem Solving Tip *(continued)*
multiple bond formation, 352
naming aldehydes, ketones, and carboxylic acids, 926
pH during acid–base reaction, 654
pH of equal molar amounts of acid and base, 615
preparing a solution by dilution, 160
reactions with a limiting reactant, 148
recognizing gas-forming reactions, 124
relating rate equations and reaction mechanisms, 548
stoichiometry calculations, 141
stoichiometry calculations involving solutions, 166
using a calculator, 34
using Hess's law, 207
using the quadratic formula, 571
writing net ionic equations, 113
product(s) A substance formed in a chemical reaction, 16, 98
effect of adding or removing, 575
heat as, 578
in equilibrium constant expression, 558
rate of concentration change, 510
product-favored reaction(s) A reaction in which reactants are completely or largely converted to products at equilibrium, 103, 213
equilibrium constant for, 561
predicting, 699
proline, structure of, *947*
promethium, 993
propagation step, in chain reaction, 549, 996
propane, as fuel, 786
combustion of, balanced equation for, 101
enthalpy of combustion, 200
percent composition of, 85
structure of, 898
1,2,3-propanetriol, 918
propanoic acid, as weak acid, 594
propanol, isomers of, 918
2-propanol, structure of, 330
propene, 521, 908
hydrogenation of, 328
reaction with bromine, 912
separation by metal-organic framework, 763
propionic acid, 927t
proportionality constant, 374, 393
proportionality symbol, 515
propyl alcohol, 918
propyl propanoate, 930
propylene, 908
protein(s) A polymer formed by condensation of amino acids, sometimes conjugated with other groups, 946–953
as emulsifying agent, 500
drawing structures of, 948
energy content of, 28
molar masses of, 948
structural levels of, 949
synthesis, DNA and, 959–961
testing food for, 422
protium, 48, 809
proton(s) A positively charged subatomic particle found in the nucleus, 45
bombardment with, 994
donation by Brønsted acid, 117, 586
nuclear stability and, 983
proton exchange membrane (PEM), 733
Prussian blue, 859
pseudo-first-order reaction, 516
p-type semiconductor, 455
pufferfish, 584
pure substance A form of matter that cannot be separated into two different species by any physical technique, and that has a unique set of properties, 8
purification, of mixtures, 9
of water, 772
putrescine, 921
pyrite, iron, 11
pyrometallurgy Recovery of metals from their ores by high-temperature processes, 864
pyrophosphate ion, complex with manganese(III) ion, 743
pyrophosphoric acid, 841t
pyroxenes, structure of, 829

quadratic equations, A-4
quadratic formula, use in concentration problems, 568–571
qualitative information Nonnumerical experimental observations, such as descriptive or comparative data, 4, 23
quantitative analysis, 150
quantitative information Numerical experimental data, such as measurements of changes in mass or volume, 4, 23
quantity, of pure substance, 78
quantization, of electron spin, 243
of electron's potential energy, 228, 236
Planck's assumption of, 222
quantum mechanics A general theoretical approach to atomic behavior that describes the electron in an atom as a matter wave, 235–238
quantum number(s) A set of numbers with integer values that define the properties of an atomic orbital, 237
allowed values of, 237, 238t
angular momentum, 237
magnetic, 237
Pauli exclusion principle and, 250
principal, 228, 237
spin, 243
quartz, 828
structure of, *457*
synthesis of, 829
quaternary structure, of protein, 950
quenching, in steel production, 867

rad A unit of radiation dosage, 998
radial distribution plot, atomic orbital, *239*, 240
radiation, background, 999
cancer treatment with, 1003
cosmic, 999
electromagnetic, 220
health effects of, 998–1000
safe exposure, 1000
treatment of food with, 1005
units of, 998
radiation absorbed dose (rad), 998
radioactive decay series A series of nuclear reactions by which a radioactive isotope decays to form a stable isotope, 978
radioactivity, discovery of, 54
natural, 976
radiocarbon dating, 990
radioisotopes, uses in medical procedures, 1001t
radium, 54
abundance of, 817
from decay of uranium, 979
radius, atomic, 267
covalent, 268
ionic, 274, 460
radon, abundance of, 852
from decay of uranium, 979
radioactive half-life of, 528
radon-222, radioactive half-life, 990
radura, on packages of irradiated food, *1005*
Ramsay, Sir William, 92, 579
Raoult's law The vapor pressure of the solvent is proportional to the mole fraction of the solvent in a solution, 484
rare earth elements. *See* **lanthanide(s)**.
rare gas(es). *See* **noble gas(es)**.
Raschig reaction, 545, 835
rate. *See* **reaction rate(s)**.
rate constant (*k*) The proportionality constant in the rate equation, 515
Arrhenius equation for, 533
calculating, 517
for radioactivity, 989
half-life and, 526
units of, 516
rate equation(s) The mathematical relationship between reactant concentrations and reaction rate, 515
determining, 517
first-order, nuclear, 989
for elementary step, 541
graphical determination of, 524
integrated, 520–529
for nuclear decay, 989
reaction mechanisms and, 543–549
stoichiometry and, 529
rate law. *See* **rate equation(s)**.
rate-determining step The slowest elementary step of a reaction mechanism, 544

Rayleigh, Lord (John William Strutt), 92
reactant(s) A starting substance in a chemical reaction, 16, 98
concentration of, reaction rate and, 515–520
effect of adding or removing, 575
heat as, 578
in equilibrium constant expression, 558
rate of concentration change, 510
reactant-favored reaction(s) A reaction in which only a small amount of reactants is converted to products at equilibrium, 105, 213
equilibrium constant for, 561
predicting, 699
reaction(s) A process in which substances are changed into other substances by rearrangement, combination, or separation of atoms, 16. *See also* under element, compound, or chemical group of interest.
(n, γ), 994
acid–base, 119–121. *See also* **acid–base reaction(s)**.
addition, 910
autoionization, 589
chain, 548, 768, 972, 996
condensation, 937, 948, 954
coupling of, 706
decomposition, 133
direction of, reaction quotient and, 562
disproportionation, 850
electron transfer, 712–761. *See also* **oxidation–reduction reaction(s)**.
enthalpy change for, 198–201, 209
enzyme-catalyzed cleavage, 952
esterification, 927
exchange, 110, 132
free energy change for, 697
Friedel–Crafts, 626
gas laws and, 386
gas-forming, 123, 133
hydrogenation, 328
hydrolysis, 928
in aqueous solution, 106
stoichiometry of, 164–172
types of, 130–134
moles of, 148, 198, 510
neutralization, 120, 604
neutron capture, 994
nuclear, 977–981
artificial, 992–995
rates of, 987–992
order of. *See* reaction order.
oxidation of alcohols, 924
oxidation of organic compounds, 901
oxidation–reduction, 125–131. *See also* **oxidation–reduction reaction(s)**.
precipitation, 110–114, 132, 655–666
solubility product constant and, 667–670
product-favored vs. reactant-favored, 103, 213, 561, 680
predicting, 699
proton transfer. *See* **acid–base reaction(s)**.
Raschig, 835
rate of. *See* **reaction rate(s)**.
reduction of aldehydes and ketones, 925
reduction of carboxylic acids, 927
reverse, equilibrium constant expression for, 572
reversibility of, 102, 556
spontaneity of, predicting, 691–697
standard enthalpy of, 198, 510
standard reduction potentials of, 737, 738t
substitution, 542, 915
sum of, equilibrium constant expression for, 572
synthesis, 133
thermite, 138
transesterification, 937
water–gas, 787, 811
reaction coordinate diagram, 531, 537, 538
reaction intermediate A species that is produced in one step of a reaction mechanism and completely consumed in a later step, 537
identification of, 550
in rate equation, 546
reaction mechanism(s) The sequence of events at the molecular level that control the speed and outcome of a reaction, 508, 539–549
effect of catalyst on, 537
free-radical chain reaction in, 548
initial equilibrium step in, 546–548
rate equation and, 543–549
rate-determining step of, 544
verification of, 550
reaction order The exponent of a concentration term in the reaction's rate equation, 515
determining, 517
molecularity and, 541
reaction quotient (*Q*) The product of concentrations of products divided by the product of concentrations of reactants, each raised to the power of its stoichiometric coefficient in the chemical equation, 562. *See also* **equilibrium constant**.
calculating free energy change from, 707
Gibbs free energy change and, 699
relation to cell potential, 744
solubility product constant and, 667
reaction rate(s) The change in concentration of a reagent per unit time, 506–553
Arrhenius equation and, 533
average versus instantaneous, 509
catalysts and, 535–538
collision theory of, 530–538
conditions affecting, 512–514
effect of concentration, 530
effect of molecular orientation, 532, 538
effect of temperature, 532
expression for. *See* **rate equation(s)**.
initial, 517
radioactive disintegration, 987–992
stoichiometry and, 510
receptor proteins, 966
rechargeable battery, 729, 731
recycling, 779
redox reaction(s). *See* **oxidation–reduction reaction(s)**.
reducing agent(s) The substance that donates electrons and is oxidized in an oxidation–reduction reaction, 125–126, 715
relative strengths of, 737, 740–742
reduction The gain of electrons by an atom, ion, or molecule, 126
at cathode of electrochemical cell, 723, 751
half-reaction for, 715
reduction potential(s), standard, 737, 738t, A-34
reduction reaction(s), of aldehydes and ketones, 925
of carboxylic acids, 927
reformation, in petroleum refining, 785
relative atomic mass The ratio of the average mass per atom of an element to 1/12 of the mass of an atom of ^{12}C, 50. *See also* **atomic weight**.
rem A unit of radiation dosage to biological tissue, 998
renewable resources, 778, 788
replication, of DNA, 958
resin, in ion exchanger, 820
resonance, molecular orbital theory and, 362–365
resonance stabilization, 915
resonance structure(s) The possible structures of a molecule for which more than one Lewis structure can be written, differing by the number of bond pairs between a given pair of atoms, 298–302
amides, 930
benzene, 299, 353, 913
carbonate ion, 299
effect on acid strength, 620
nitrate ion, 299
ozone, 298
resources, energy, 778
respiration, 968, 970
production of ATP by, 706
respiratory alkalosis and acidosis, 645
retroviruses, 962
reverse osmosis The application of pressure greater than the osmotic pressure of impure solvent to force solvent through a semipermeable membrane to the region of lower solute concentration, 492, 774
reverse transcriptase, 963
reversibility, equilibrium and, 556
of chemical reactions, 102
reversible process A process for which it is possible to return to the starting conditions along the same path without altering the surroundings, 682
rhodochrosite, 656, 658
rhubarb, oxalic acid in, 630
ribonucleic acid, 956
hydrogen bonding in, 414

  sodium and potassium ions in, 813
Seaborg, Glenn T., 992
seaweed, iodine in, 848
second, definition of, A-10
second law of thermodynamics The total entropy of the universe is continually increasing, 682
secondary alcohols, 924
secondary amines, 921
secondary battery, 729
secondary colors, 889
secondary structure, of protein, 949
second-order reaction, 516
  half-life of, 526
  integrated rate equation, 523
seesaw molecular geometry, 311, *312*
selenium, abundance of, 843
  uses of, 845
semiconductor(s) Substances that can conduct small quantities of electric current, 454–456
  band theory of, 454
semimetals. *See* **metalloid(s)**.
semipermeable membrane A thin sheet of material through which only certain types of molecules can pass, 489
serial dilution, 162
serine, structure of, *947*
setae, on gecko's toes, 404
shell, electron, 237
SI Abbreviation for Système International d'Unités, a uniform system of measurement units in which a single base unit is used for each measured physical quantity, 23, A-10
sickle cell anemia, 950
sievert The SI unit of radiation dosage to biological tissue, 999
sigma (σ) bond(s) A bond formed by the overlap of orbitals head to head, and with bonding electron density concentrated along the axis of the bond, 341
  in molecular orbital theory, 355
sign conventions, for electron affinity, 273
  for energy calculations, 194t
  for voltaic cells, 723, *725*
significant figure(s) The digits in a measured quantity that are known exactly, plus one digit that is inexact to the extent of ±1, 33–37
  in molar masses, 79
  logarithms and, A-3
silane, reaction with water, 803
silica, 828
silica gel, 829
silicates, minerals containing, 829
  structure of, 459
silicon, abundance of, 827
  as semiconductor, 455
  bond energy compared to carbon, 901
  chemistry of, 827–833
  comparison with carbon, 802
  compounds of, 60
  electron configuration of, 258
  purification of, 828
  similarity to boron, 822
silicon carbide, crystal structure of, 449
silicon dioxide, 829
  reaction with hydrogen fluoride, 849
silicon tetrachloride, 828
  molecular geometry of, 308
silicone polymers, 832
Silly Putty, 832

silt, formation of, *500*
silver, as bacteriocide, 131, 799
silver acetate, solubility of, 661
silver bromide, solubility of, 656
  solubility of, in aqueous thiosulfate ion, 673
silver chloride, free energy change of dissolution, 705
  K_{sp} of, 750
  solubility of, 660, 668
    in aqueous ammonia, 572, 672
silver chromate, formation by precipitation, 111
  solubility of, 172, 661, 663
silver nitrate, reaction with potassium chloride, 110, 112
silver oxide battery, 730
simple cubic (sc) unit cell, 439
single bond A bond formed by sharing one pair of electrons; a sigma bond, 341
slag, in blast furnace, 866
slaked lime, 122, 821
  in water purification, 773
slime, *935*
slope, of straight line graph, 41, 510, *524*
Smalley, Richard, 777
smog, 790
  photochemical, 766
snot-tites, 844
soap A salt produced by the hydrolysis of a fat or oil by a strong base, 500
  hard water and, 820
soapstone, 817
soda ash. *See* sodium carbonate.
Soddy, Frederick, 977
sodium, abundance of, 812
  preparation of, 813
  reaction with chlorine, 3, 284
  reaction with water, *4*
  salts of, in fireworks, 233
sodium acetate, calculating pH of aqueous solution, 610
  in heat pack, 474
sodium azide, in air bags, 372, 379
sodium bicarbonate, 815. *See also* sodium hydrogen carbonate.
  reaction with acetic acid, 602
sodium borohydride, 825
  as reducing catalyst, 925
sodium bromide, bromine production from, 848
sodium carbonate, 158, 815
  calculating pH of aqueous solution, 616
  primary standard for acid–base titration, 168
sodium chloride, as strong electrolyte, 106
  composition of, 3, 11
  crystal lattice of, 73, 446
  electrolysis of, 386, 752, 813, *816*
  enthalpy of solution, 476
  entropy of solution process, 693
  lattice enthalpy calculation for, 451
  melting ice and, 495
  oxidation by dichromate ion, 847
  reaction with sulfuric acid, 850
  standard molar enthalpy of formation of, 209
  structure of, *438*
sodium cyanide, extraction of gold with, 674
sodium glycinate, 306
sodium halides, aqueous, products of electrolysis of, 756
sodium hydrogen carbonate, reaction with citric acid, 130
  reaction with tartaric acid, 124
sodium hydroxide, enthalpy of solution, 476
  production of, 815, 847
  reaction with acetic acid, 120
  reaction with aluminum, 812
  reaction with formic acid, 604
  reaction with hydrogen chloride, 119
  reaction with nitric acid, 120
  titration of acetic acid with, 647–650
  titration with hydrochloric acid, 644
sodium hypochlorite, 173
  as disinfectant, 773
  in bleach, 472
  reaction with ammonia, 835
sodium iodide, aqueous, electrolysis of, 753
sodium ions, in ion exchanger, 820
  pumping in cells, 969
sodium laurylbenzenesulfonate, structure of, 501
sodium monofluorophosphate, in toothpaste, 821
sodium monohydrogen phosphate, 842
sodium nitrate, 816
sodium perchlorate, 851
sodium peroxide, 815
sodium phosphate, 842
sodium silicate, 829
sodium stearate, as soap, 500
sodium sulfate, quantitative analysis of, 151–152
  reaction with barium chloride, 113
sodium thiosulfate, reaction with iodine, 173
sol A colloidal dispersion of a solid substance in a fluid medium, 498
solid(s) The phase of matter in which a substance has both definite shape and definite volume, 6
  amorphous, 459
  chemistry of, 436–467
  concentration of, in equilibrium constant expression, 559
  dissolution in liquids, 474
  ionic, 444–449
  molecular, 456
  network, 457
  types of, 457t
solidifier, for cleaning spilled oil, 797
solubility The concentration of solute in equilibrium with undissolved solute in a saturated solution, 474
  common ion effect and, 661–664
  estimating from solubility product constant, 658–661
  factors affecting, 479–483
  intermolecular forces and, 410, 476
  of complex ions, 670–674
  of gases in water, 417t
  of ionic compounds in water, 108
  of salts, 655–666
  temperature and, 481–483
  undissociated salt and, 662
solubility product constant (K_{sp}) An equilibrium constant relating the concentrations of the ionization products of a dissolved substance, 656
  calcium carbonate, 795
  calculating free energy change from, 705
  reaction quotient and, 667
  standard potential and, 750
  values of, A-23
solute The substance dissolved in a solvent to form a solution, 105, 470
solution(s) A homogeneous mixture in a single phase, 8–10, 105, 468–505
  acidic and basic, redox reactions in, 718–722
  aqueous, balancing redox equations, 718–722
    pH and pOH of, 161–164, 591
    reactions in, 105
  boiling process in, 486
  buffer. *See* **buffer solution(s)**.
  concentrations in, 156–161
  enthalpy of, 475–479
  ideal, 484
  osmosis in, 489
  process of forming, 473–479
  Raoult's law, 484
  saturated, 473
  supersaturated, 474
solvation, effect on acid strength, 619
  enthalpy of, 408
Solvay process, 815
solvent The medium in which a solute is dissolved to form a solution, 105, 470
sorbent, for cleaning spilled oil, 797
soy protein, adhesive made from, 940
space-filling models, 65, 900
spatulae, on gecko's toes, 404
***spdf* notation** A notation for the electron configuration of an atom in which the number of electrons assigned to a subshell is shown as a superscript after the subshell's symbol, 237, 256
specific heat capacity (*C*) The quantity of heat required to raise the temperature of 1.00 g of a substance by 1.00 kelvin, 184–189
  hydrogen bonding and, 415
  values of, A-14t

spectator ion(s) An ion that is present in a solution in which a reaction takes place, but that is not involved in the net process, 112
spectrochemical series An ordering of ligands by the magnitudes of the splitting energies they cause, 890–893
spectrometer, mass, 49
spectrophotometer, *175*
spectrophotometry An analytical method based on the absorption and transmission of specific wavelengths of light, 172–177
spectroscope, photoelectron, 272
spectrum, absorption, 173, 890
electromagnetic, *221*, 888
continuous, *221*, *223*, 227
line, 226
of heated body, 222
solar, *244*
speed(s), of gas molecules, 391
of wave, 220
spin, electron, 243
sponge, skeletal structure of, *25*, 26
spontaneous reaction, 680. *See also* **product-favored reaction(s)**.
effect of temperature on, 695
Gibbs free energy change and, 697
relation to enthalpy and entropy, 694t
square planar molecular geometry, 311, *312*, 876
optical isomerism and, 881
square pyramidal molecular geometry, 311, *312*
stability, nuclear, band of, 983
of organic compounds, 901
standard enthalpy of formation and, 209
stabilization, resonance, 915
stainless steel, 866
stalactites and stalagmites, 102
standard atmosphere (atm) A unit of pressure; 1 atm = 760 mm Hg, 372, A-7
standard conditions In an electrochemical cell, all reactants and products are pure liquids or solids, or 1.0 M aqueous solutions, or gases at a pressure of 1 bar, 734. *See also* **standard state**.
standard deviation A measure of precision, calculated as the square root of the sum of the squares of the deviations for each measurement from the average, divided by one less than the number of measurements, 31
standard entropy change of reaction ($\Delta_r S°$) The sum of the standard molar entropies of the products, each multiplied by its stoichiometric coefficient, minus the sum of the standard molar entropies of the reactants, each multiplied by its stoichiometric coefficient, 689
standard free energy change of reaction ($\Delta_r G°$) The free energy change for a reaction in which all reactants and products are in their standard states, 697
cell potential and, 748
relation to equilibrium constant, 704
standard hydrogen electrode (SHE), 735
zero voltage assigned to, 737
standard molar enthalpy of formation ($\Delta_f H°$) The enthalpy change of a reaction for the formation of one mole of a compound directly from its elements, all in their standard states, 208, 680
enthalpy of solution calculated from, 478
values of, A-26
standard molar enthalpy of fusion ($\Delta_{fus} H°$) The quantity of heat required to convert 1 mol of a solid to a liquid at 1 bar and constant temperature, 200
standard molar enthalpy of vaporization ($\Delta_{vap} H°$) The quantity of heat required to convert 1 mol of a liquid to a gas at 1 bar and constant temperature, 200, 417t, 423
standard molar entropy ($S°$) The entropy of a substance in its most stable form at a pressure of 1 bar, 687
values of, A-26
standard molar free energy of formation ($\Delta_f G°$) The free energy change for the formation of one mole of a compound from its elements, all in their standard states, 700
values of, A-26
standard molar volume The volume occupied by 1 mol of gas at standard temperature and pressure; 22.414 L, 382
standard potential ($E°_{cell}$) The potential of an electrochemical cell measured under standard conditions, 735
calculation of, 737
equilibrium constant calculated from, 749
of alkali metals, 814t
standard reaction enthalpy ($\Delta_r H°$) The enthalpy change of a reaction that occurs with all reactants and products in their standard states, 198
product-favored vs. reactant-favored reactions and, 213
standard reduction potential(s), 737, 738t
of halogens, 847t
of transition metals, 860
values of, A-34
standard state The most stable form of an element or compound in the physical state in which it exists at 1 bar and the specified temperature, 198, 680
in biochemical reactions, 706
standard temperature and pressure (STP) A temperature of 0 °C and a pressure of exactly 1 atm, 382
standardization The accurate determination of the concentration of an acid, base, or other reagent for use in a titration, 168
standing wave A single-frequency wave having fixed points of zero amplitude, 235
Staphylococcus aureus, 857
starch, 955, *956*
starch-iodide paper, 173
stars, elements formed in, 45
state(s), changes of, 189
ground and excited, 228, 977
physical, entropy and, 688
in chemical equations, 98
of matter, 6, 406
reaction enthalpy and, 199
standard. *See* **standard state**.
state function A quantity whose value is determined only by the state of the system, 197, 680
stationary phase, in chromatography, 432
steam reforming, 787
stearic acid, 926t
steel, production of, 866
strength of, 867
stereoisomers Two or more compounds with the same molecular formula and the same atom-to-atom bonding, but with different arrangements of the atoms in space, 899
sterilization, 772
by irradiation, 1005
Stern, Otto, 243
steroids, 966
stibnite, 658
STM. *See* scanning tunneling microscope.
stoichiometric coefficients The multiplying numbers assigned to the species in a chemical equation in order to balance the equation, 98
electrochemical cell potential and, 739
exponents in rate equation vs., 515
fractional, 199
in calculating enthalpy of formation, 209
in equilibrium constant expression, 559, 571
stoichiometric factor(s) A conversion factor relating moles of one species in a reaction to moles of another species in the same reaction, 140, 386
in solution stoichiometry, 165
stoichiometry The study of the quantitative relations between amounts of reactants and products, 98
ICE table and, 558
ideal gas law and, 386
mass relationships in, 138–143
of reactions in aqueous solution, 164–172
rate equation of elementary step and, 541

rate equations and, 529
reaction rates and, 510
unit cell and, 438
storage battery, 731
STP. *See* **standard temperature and pressure**.
strained hydrocarbons, 907
Strassman, Fritz, 996
strategies, problem-solving, 41–43
stratosphere, 392, 764
strike anywhere match, 839
strong acid(s) An acid that ionizes completely in aqueous solution, 116, 593
reaction with strong base, 603
reaction with weak base, 604
titration of, 644
strong base(s) A base that ionizes completely in aqueous solution, 116, 593
strong electrolyte A substance that dissolves in water to form a good conductor of electricity, 106
strontium, abundance of, 817
isotope ratio of, 53, 1005
salts of, in fireworks, 233
strontium-90, radioactive half-life, 988
structural formula A variation of a molecular formula that expresses how the atoms in a compound are connected, 64, 900, 905
structural isomers Two or more compounds with the same molecular formula but with different atoms bonded to each other, 899, 1034
of alcohols, 918
of alkanes, 903
of alkenes, 908
structure, molecular, 283
Strutt, John William (Lord Rayleigh), 92
styrene, structure of, 914
styrene-butadiene rubber (SBR), 936
Styrofoam, 933t
Styron, 933t
subatomic particles A collective term for protons, neutrons, and electrons, 45
properties of, 47t
sublimation The direct conversion of a solid to a gas, 193, 462
submicroscopic level Representations of chemical phenomena in terms of atoms and molecules; also called particulate level, 8
entropy at, 684
subscript, in chemical formula, 12
subshells, electron, 237
labels for, 237
number of electrons in, 251t
order of energies of, 251
substance(s), pure A form of matter that cannot be separated into two different species by any physical technique, and that has a unique set of properties, 8
substance(s), pure, amount of, 78
substituent group(s) A group of atoms attached to an organic molecule, replacing a hydrogen atom, 905
common, A-16t
substitution reaction(s), bimolecular, mechanism of, 542
of aromatic compounds, 915
substrate, in enzyme-catalyzed reaction, 540, 952
successive approximations, method of, 569, 610
successive equilibria, 671
succinic acid, reaction with 1,2-ethylenediamine, 939
sucrose, as nonelectrolyte, 107
enthalpy of combustion, 200
half-life of decomposition, 527
structure of, 954
sugar, dietary Calories in, *200*
sugar cane, biofuel from, 788
sulfate ion, resonance structures of, 300
sulfide(s), in black smokers, 96
roasting of, 845
solubility of, 666
sulfonate group, in detergents, 501
sulfur, abundance of, 843
allotropes of, 61, 843
chemistry of, 845
combustion of, 559
compounds with phosphorus, 839
electron configuration of, 259
in coal, 781, 845
in gunpowder, 214
in iron pyrite, 11
in vulcanized rubber, 935
mining of, *122*
natural deposits of, 843
reaction with oxygen, 63, 100
removed from pig iron, 866
sulfur dioxide, as Lewis acid, 624
as refrigerant, 768
production of, 845
reaction with oxygen, 564
reaction with water, 122
sulfur hexafluoride, 303
molecular orbitals in, 364
sulfur oxides, air pollution by, 845
sulfur tetrafluoride, molecular polarity of, 323
sulfur trioxide, 846
sulfuric acid, as polyprotic acid, 587
in lead storage battery, 731
production of, 846
properties and uses of, 122
reaction with calcium fluoride, 849
reaction with calcium phosphate, 846
reaction with nickel(II) carbonate, 124
reaction with sodium chloride, 850
reaction with water, 117
Sullivan, John H., 550
Sun, chemistry of, 244
sun protection factor (SPF), 225
sunscreens, 225
superacid(s), 627
superconductivity, 779
superconductor(s) A material that has no resistance to the flow of electric current, 135
supercritical fluid A substance at or above the critical temperature and pressure, 429, 465
superoxide ion, molecular orbital configuration of, 362
superoxides, 815
oxidation number of oxygen in, 127
superphosphate fertilizer, 846
supersaturated solution(s) A solution that temporarily contains more than the saturation amount of solute, 474
reaction quotient in, 667
surface area, of colloid, 499
reaction rate and, 514
surface density plot, atomic orbital, *239*, 240
surface science, 398
surface tension The energy required to disrupt the surface of a liquid, 430
detergents and, 501
surfactant(s) A substance that changes the properties of a surface, typically in a colloidal dispersion, 500
surroundings Everything outside the system in a thermodynamic process, 182, 680
entropy change for, 692
suspension A distribution of solid particles within a solvent, which gradually separate and settle to the bottom of the container, 498
sustainability, 5–6
sweat, cooling by, 425
symbol(s), in chemistry, 8, 10, 12
symmetry, chirality and, 900
molecular polarity and, 322
synthesis reaction(s) A reaction in which a compound is prepared from elements or other compounds, 133
system The substance being evaluated for energy content in a thermodynamic process, 182, 680
entropy change for, 692
isolated, energy changes in, 187
systematic names, 905, A-15
Système International d'Unités, 23, A-10

talc, 817
Taq polymerase, 972
tar sands, 783
tartaric acid, 926t
as polyprotic acid, *587*
reaction with sodium hydrogen carbonate, 124

uncertainty principle, 236
unimolecular process, 541
unit(s), canceling in conversion calculation, 38
  of measurement, 23–28, 372
  SI, 23
unit cell(s) The smallest repeating unit in a crystal lattice that has the characteristic symmetry of the solid, 438
  counting atoms in, 441
  shapes of, *439*
universe, entropy change for, 693
  total energy of, 18
unpaired electrons, in transition metal ions, 860
unsaturated compound(s) A hydrocarbon containing double or triple carbon–carbon bonds, 910
unsaturated fatty acids, 965
unsaturated solution(s), reaction quotient in, 667
ununoctium, discovery of, 993
ununseptium, discovery of, 993
uracil, in RNA, 956, *957*
uranium, isotopes of, 974
  isotopic enrichment, 997
  isotopic separation, 850
  radioactive series from, 978
uranium-235, fission of, 996
uranium-238, radioactive half-life, 987
uranium hexafluoride, 850, 861, 997
urine, phosphorus distilled from, 841

vacuum chamber, 398
valence band, 454
valence bond theory A model of bonding in which a bond arises from the overlap of atomic orbitals on two atoms to give a bonding orbital with electrons localized between the atoms, 340–354
valence electron(s) The outermost and most reactive electrons of an atom, 256, 262, 285
  Lewis symbols and, 285
  of main group elements, 805
valence shell electron-pair repulsion (VSEPR) model A model for predicting the shapes of molecules, in which structural electron pairs are arranged around each atom to maximize the angles between them, 307
valeric acid, 927t
valine, structure of, *947*
van Arkel, Anton Eduard, 854
van Arkel–Ketelaar diagram, 284, 854
van der Waals, Johannes, 400
van der Waals equation A mathematical expression that describes the behavior of nonideal gases, 400
van der Waals force(s), 407, 420
van't Hoff, Jacobus Henrikus, 496
van't Hoff factor The ratio of the experimentally measured freezing point depression of a solution to the value calculated from the apparent molality, 496
vancomycin-resistant *Enterococcus* (VRE), 857
vapor pressure The pressure of the vapor of a substance in contact with its liquid or solid phase in a sealed container, 425–428
  Raoult's law and, 484
  relation to enthalpy of vaporization, 427
vaporization The state change from liquid to gas, 189, 421
  enthalpy of, 424t
  enthalpy of, intermolecular forces and, 409
  heat of, 189
Vectra, 933t
velocity, of wave, 220

PHYSICAL AND CHEMICAL CONSTANTS

Avogadro's number	$N_A = 6.02214129 \times 10^{23}$/mol	π	$\pi = 3.1415926536$
Electronic charge	$e = 1.60217657 \times 10^{-19}$ C	Planck's constant	$h = 6.6260696 \times 10^{-34}$ J · s
Faraday's constant	$F = 9.6485337 \times 10^{4}$ C/mol electrons	Speed of light (in a vacuum)	$c = 2.99792458 \times 10^{8}$ m/s
Gas constant	$R = 8.314462$ J/K · mol $= 0.082057$ L · atm/K · mol		

USEFUL CONVERSION FACTORS AND RELATIONSHIPS

Length

SI unit: Meter (m)

1 kilometer = 1000 meters
= 0.62137 mile
1 meter = 100 centimeters
1 centimeter = 10 millimeters
1 nanometer = 1.00×10^{-9} meter
1 picometer = 1.00×10^{-12} meter
1 inch = 2.54 centimeter (exactly)
1 Ångstrom = 1.00×10^{-10} meter

Mass

SI unit: Kilogram (kg)

1 kilogram = 1000 grams
1 gram = 1000 milligrams
1 pound = 453.59237 grams = 16 ounces
1 ton = 2000 pounds

Volume

SI unit: Cubic meter (m^3)

1 liter (L) = 1.00×10^{-3} m^3
= 1000 cm^3
= 1.056710 quarts
1 gallon = 4.00 quarts

Energy

SI unit: Joule (J)

1 joule = 1 kg · m^2/s^2
= 0.23901 calorie
= 1 C × 1 V
1 calorie = 4.184 joules

Pressure

SI unit: Pascal (Pa)

1 pascal = 1 N/m^2
= 1 kg/m · s^2
1 atmosphere = 101.325 kilopascals
= 760 mm Hg = 760 torr
= 14.70 lb/in^2
= 1.01325 bar
1 bar = 10^5 Pa (exactly)

Temperature

SI unit: kelvin (K)

0 K = −273.15 °C
K = °C + 273.15°C
? °C = (5 °C/9 °F)(°F − 32 °F)
? °F = (9 °F/5 °C)(°C) + 32 °F

†The atomic weights of many elements can vary depending on the origin and treatment of the sample. This is particularly true for Li; commercially available lithium-containing materials have Li atomic weights in the range of 6.939 and 6.996. The uncertainties in atomic weight values are given in parentheses following the last significant figure to which they are attributed.

*Elements with no stable nuclide; the value given in parentheses is the atomic mass number of the isotope of longest known half-life. However, three such elements (Th, Pa, and U) have a characteristic terrestrial isotopic composition, and the atomic weight is tabulated for these. **http://www.chem.qmw.ac.uk/iupac/AtWt/**
