16-3 Hydrolysis of Aliphatic Nitro Compounds

Oxo-de-hydro,nitro-bisubstitution

Primary or secondary aliphatic nitro compounds can be hydrolyzed, respectively, to aldehydes or ketones, by treatment of their conjugate bases with sulfuric acid. This is called the *Nef reaction*.[88] Tertiary aliphatic nitro compounds do not give the reaction because they cannot be converted to their conjugate bases. Like **16-2**, this reaction involves hydrolysis of a C=N double bond. A possible mechanism involves initial formation of the *aci form* of the nitro compound (**11**):[89]

Intermediates of type **12** have been isolated in some cases.[90]

The conversion of nitro compounds to aldehydes or ketones has been carried out with better yields and fewer side reactions by several alternative methods.[91] Among these are treatment of the nitro compound with basic H_2O_2 in an ionic liquid,[92] or 30% H_2O_2—K_2CO_3,[93] DBU in acetonitrile,[94] or CAN.[95]

When *primary* nitro compounds are treated with sulfuric acid without previous conversion to the conjugate bases, they give carboxylic acids. Hydroxamic acids are intermediates and can be isolated, so that this is also a method for their preparation.[96] Both the *Nef reaction* and the hydroxamic acid process involve the *aci form*; the difference in products arises from

higher acidity. For example, a difference in sulfuric acid concentration from 2 to 15.5 M changes the product from the aldehyde to the hydroxamic acid.[97] The mechanism of the hydroxamic acid reaction is not known with certainty, but if higher acidity is required, it may be that the protonated *aci form* of the nitro compound is further protonated.

OS **VI**, 648; **VII**, 414. See also, OS **IV**, 573.

16-4 Hydrolysis of Nitriles

Nitriles can be hydrolyzed to give either amides or carboxylic acids.[98] The amide is formed initially, but since amides are also hydrolyzed with acid or basic treatment, the carboxylic acid is readily formed. When the acid is desired,[99] the reagent of choice is aq NaOH containing ~ 6–12% H_2O_2, but acid-catalyzed hydrolysis is also carried out. The reaction of nitriles with TFA–acetic acid–sulfuric acid, followed by treatment with water gives the corresponding amide.[100] A Rh catalyzed hydrolysis with aq isopropyl alcohol leads to the amide.[101] A "dry" hydrolysis of nitriles has been reported.[102] Enzymatic hydrolysis to give the amide was reported with nitrilase (ZmNIT2).[103] Nitriles can be hydrolyzed to the carboxylic acids without disturbing carboxylic ester functions also present, by the use of tetrachloro- or tetrafluorophthalic acid.[104]

Hydrolysis of cyanohydrins [RCH(OH)CN] is usually carried out under acidic conditions, because basic solutions cause competing reversion of the cyanohydrin to the aldehyde and CN^-. However, cyanohydrins have been hydrolyzed under basic conditions with borax or alkaline borates.[105]

There are a number of procedures for stopping at the amide stage,[106] among them the use of concentrated H_2SO_4; 2 molar equivalents of chlorotrimethylsilane followed by H_2O,[107] aq NaOH with PEG-400 and microwave irradiation,[108] heating on neutral alumina,[109] or dry HCl followed by H_2O. The same result can also be obtained by use

of water and certain metal ions or complexes[110] including an In,[111] Au,[112] or a Ru catalyst.[113] Other reagents include MnO_2/SiO_2 with microwave irradiation,[114] or $Hg(OAc)_2$ in HOAc.[115] The reaction of ferric nitrate and an amine generates the amide.[116]

Nitriles are converted to thioamides [$ArC(=S)NH_2$] with ammonium sulfide [$(NH_4)_2S$] in methanol, with microwave irradiation.[117] Thioamides are also prepared using phosphorus pentasulfide.[118]

Thiocyanates are converted to thiocarbamates in a similar reaction:[119] R—S—C≡N + H_2O → R—S—CO— NH_2. Hydrolysis of cyanamides gives amines, produced by the breakdown of the unstable carbamic acid intermediates: $R_2NCN \rightarrow [R_2NCOOH] \rightarrow R_2NH$.

B. Attack by OR (Addition of ROH)

16-5 The Addition of Alcohols to Aldehydes and Ketones

Dialkoxy-de-oxo-bisubstitution

Dithioalkyl-de-oxo-bisubstitution

Acetals and ketals are formed by treatment of aldehydes and ketones, respectively, with alcohols in the presence of acid catalysts.[120] Lewis acid derivatives of Ti,[121] Cu,[122] In,[123] Ru,[124] or Co[125] can be used in conjunction with alcohols. Organocatalysts have been used for this conversion under acid-free conditions.[126] This reaction is reversible, and acetals and ketals can be hydrolyzed by treatment with acid.[127] With small unbranched aldehydes the equilibrium lies to the right. If ketals or acetals of larger molecules must be prepared the equilibrium must be shifted, usually by removal of water. This can be done by azeotropic distillation, ordinary distillation, or the use of a drying agent (e.g., Al_2O_3 or a molecular sieve).[128] The reaction is not

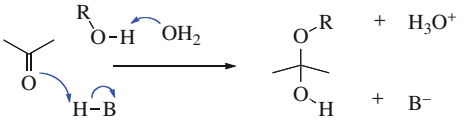
catalyzed in either direction by bases, so most acetals and ketals are quite stable to bases, though they are easily hydrolyzed by acids. This reaction is therefore a useful method of protection of aldehyde or ketone functions from attack by bases. The reaction is of wide scope.



Most aldehydes are easily converted to acetals,[129] but the reaction with ketones is more difficult, presumably for steric reasons. While the reaction often fails, many ketals, especially from cyclic ketones, have been made in this manner.[130] Many functional groups may be present without being affected. 1,2- and 1,3-Diols form cyclic acetals and ketals (1,3-dioxolanes[131] and 1,3-dioxanes,[132] respectively), and these are often used to protect aldehydes and ketones. Chiral dioxolanes have been prepared from chiral diols.[133] Dioxolanes have been prepared from ketones in ionic liquids.[134] Ketones are converted with dimethyl ketals by electrolysis with NaBr in methanol.[135] Intramolecular reactions are possible in which a keto diol or an aldehyde diol generates a bicyclic ketal or acetal.

The conversion of acetals back to aldehydes or ketones is accomplished by many reagents, including aq acid. Heating with water under microwave irradiation converts acetals to the corresponding carbonyl compound.[136] Transition metal compounds of Bi[137] catalyze this conversion as well.

The mechanism for acetal/ketal formation involves initial formation of a *hemiacetal*,[138] and it is the reverse of that given for acetal hydrolysis:

In a study of the acid-catalyzed formation of the hemiacetal, Grunwald[139] showed that the data best fit a mechanism in which the three steps shown here are actually all concerted; that is, the reaction is simultaneously catalyzed by acid and base, with water acting as the base:[140]

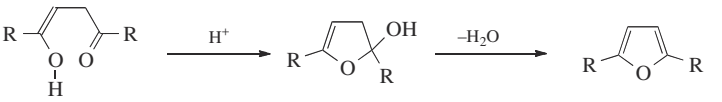
[140] See Grunwald, E. *J. Am. Chem. Soc.* ***1985****, 107*, 4710; Leussing, D.L. *J. Org. Chem.* ***1990****, 55,* 666.

Hemiacetals themselves are no more stable than the corresponding hydrates (Reaction **16-1**). If the original aldehyde or ketone has an α hydrogen, it is possible to lose water from the hemiacetal, and enol ethers can be prepared in this manner:



Similarly, treatment with an anhydride and a catalyst can give an enol ester (see Reaction **16-6**).[141] As with hydrates, it is noted that hemiacetals of cyclopropanones[142] and of polychloro and polyfluoro aldehydes and ketones may be quite stable.

When acetals or ketals are treated with an alcohol of higher molecular weight than the one already there, transacetalation is possible (see Reaction **10-13**). In another type of transacetalation, aldehydes or ketones can be converted to acetals or ketals by treatment with another acetal or ketal or with an ortho ester,[143] in the presence of an acid catalyst (shown for an ortho ester):

This method is useful for the conversion of ketones to ketals, since the direct reaction of a ketone with an alcohol often gives poor results. Alternatively, the substrate is treated with an alkoxysilane ($ROSiMe_3$) in the presence of trimethylsilyl trifluoromethanesulfonate.[144] Formic acid reacts with alcohols to give orthoformates.

1,4-Diketones give furans when treated with acids. This is actually an example of an intramolecular addition of an alcohol to a ketone, since it is the enol form that adds:

Similarly, 1,5-diketones give pyrans. Conjugated 1,4-diketones (e.g., 1,4-diphenylbut-2-en-1, 4-dione) are converted to 2,5-diphenylfuran with formic acid, 5% Pd/C, PEG-200, and a sulfuric acid catalyst with microwave irradiation.[145] Note that alkynyl ketones are converted to furans with palladium(II) acetate.[146]

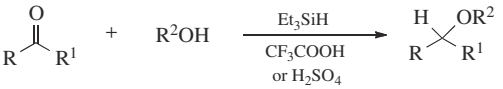
16-6 Acylation of Aldehydes and Ketones

O-Acyl-*C*-acyloxy-addition

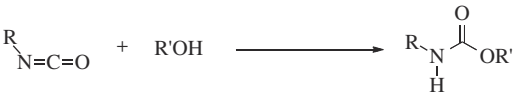


Aldehydes can be converted to *acylals* by treatment with an anhydride in the presence of proton acids,[147] NBS,[148] ceric ammonium nitrate,[149] BF_3, $LiBF_4$,[150] and Lewis acid compounds of Fe,[151] In,[152] Cu,[153] Bi,[154] W,[155] or Zr.[156] *N*-Chlorosuccinimide with thiourea is a highly efficient catalyst.[157] Silica supported perchloric acid is useful for the preparation of acylals.[158] Conjugated aldehydes are converted to the corresponding acylal by reaction with acetic anhydride and a $FeCl_3$ catalyst.[159] The reaction cannot normally be applied to ketones, though an exception has been reported when the reagent is trichloroacetic anhydride, which gives acylals with ketones without a catalyst.[160]

OS **IV**, 489.

16-7 Reductive Alkylation of Alcohols

C-Hydro-*O*-alkyl-addition



Aldehydes and ketones can be converted to ethers by treatment with an alcohol and triethylsilane in the presence of a strong acid[161] or by hydrogenation in alcoholic acid in the presence of a Pt catalyst.[162] The process can formally be regarded as addition of ROH to give a hemiacetal [$RR'C(OH)OR^2$], followed by reduction of the OH. In this respect, it is similar to Reaction **16-17**. Homoallylic ethers are formed by the Fe catalyzed reaction of acetals and aldehydes,[163] and by reactions in ionic liquids.[164] The In catalyzed reaction of aldehydes with allyltriethoxysilane leads to the corresponding ether.[165]

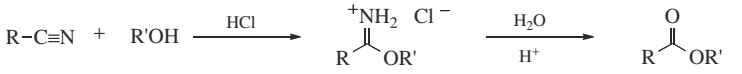
Ethers have also been prepared by the reductive dimerization of two molecules of an aldehyde or ketone (e.g., cyclohexanone → dicyclohexyl ether). This was accomplished by treatment of the substrate with a trialkylsilane and a catalyst.[166]

16-8 The Addition of Alcohols to Isocyanates

N-Hydro-*C*-alkoxy-addition

The reaction of an isocyanate with alcohols gives a carbamate (a substituted urethane). This is an excellent reaction of wide scope that gives good yields. Isocyanic acid (HNCO) gives unsubstituted carbamates. Addition of a second equivalent of HNCO gives *allophanates*.

Allophanate



The isocyanate can be generated *in situ* by the reaction of an amine and oxalyl chloride, and subsequent reaction with HCl and then an alcohol gives the carbamate.[167] Combining compounds with two NCO groups with compounds containing two OH groups makes polyurethanes. Cyclic carbamates (e.g., 1,3-oxazine-2-ones), are generated by the reaction of an isocyanate with an oxetane, in the presence of a Pd catalyst.[168] Isothiocyanates similarly give thiocarbamates (RNHCSOR′),[169] but they react slower than the corresponding isocyanates. Isocyanates react with LiAlHSeH and then iodomethane to give the corresponding selenocarbonate (RNHCOSeMe).[170]

The details of the mechanism are poorly understood,[171] but the oxygen of the alcohol certainly attacks the carbon of the isocyanate. Hydrogen bonding complicates the kinetic picture.[172] Metallic compounds, can also catalyze the addition of ROH to isocyanates[173] by light,[174] or, for tertiary ROH, by lithium alkoxides[175] or *n*-butyllithium.[176]

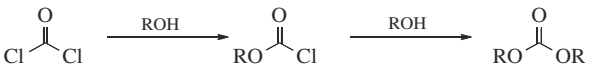
The addition of dry HCl to a mixture of a nitrile and an alcohol in the absence of water leads to the hydrochloride salt of an imino ester (imino esters are also called imidates and imino ethers). This reaction is called the *Pinner synthesis*.[177] The salt can be converted to the free imino ester by treatment with a weak base (e.g., sodium bicarbonate) or it can be hydrolyzed with water and an acid catalyst to the corresponding carboxylic ester. If the latter is desired, water may be present from the beginning, in which case aq HCl can be used and the need for gaseous HCl is eliminated. Imino esters can also be prepared from nitriles with basic catalysts.[178]

This reaction is of broad scope and is good for aliphatic, aromatic, and heterocyclic R and for nitriles with oxygen-containing functional groups. The application of the reaction to nitriles containing a carboxyl group constitutes a good method for the synthesis of mono esters of dicarboxylic acids with the desired group esterified and with no diester or diacid present.

Cyanogen chloride reacts with alcohols in the presence of an acid catalyst (e.g., dry HCl or $AlCl_3$), to give carbamates:[179]



$$ClCN + 2ROH \xrightarrow[\text{or } AlCl_3]{HCl} ROCONH_2 + RCl$$

ROH can also be added to nitriles in another manner (Reaction **16-91**).

OS **I**, 5, 270; **II**, 284, 310; **IV**, 645; **VI**, 507; **VIII**, 415.

16-10 The Formation of Carbonates and Xanthates

Di-*C*-alkoxy-addition; *S*-Metallo-*C*-alkoxy-addition

The reaction of phosgene with an alcohol generates haloformic esters, and reaction with a second equivalent of alcohol gives a carbonate. This reaction is related to the acyl addition reactions of acyl chlorides in Reaction **16-98**. An important example is the preparation of carbobenzoxy chloride ($PhCH_2OCOCl$; CbzCl) from phosgene and benzyl alcohol. When CbzCl reacts with an amine, the product is the benzyl carbamate, *N*-Cbz, which is widely used for protection of amino groups during peptide synthesis. When an alcohol reacts with certain alkyl halides (e.g., benzyl chloride) and CO_2, in the presence of Cs_2CO_3 and tetrabutylammonium iodide, a mixed carbonate is formed.[180]

The addition of alcohols to carbon disulfide (S=C=S) in the presence of a base produces xanthates.[181] The base is often HO^-, but in some cases better results can be obtained by using methylsulfinyl carbanion ($MeSOCH_2^-$).[182] If an alkyl halide (RX) is present, the xanthate ester (ROCSSR′) can be produced directly. In a similar manner, alkoxide ions add to CO_2 to give carbonate ester salts ($ROCO_2^-$).

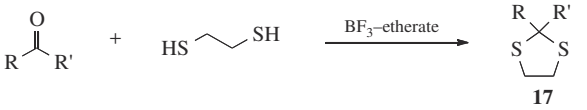
C. Sulfur Nucleophiles

16-11 The Addition of H_2S and Thiols to Carbonyl Compounds

***O*-Hydro-*C*-mercapto-addition, thioxo-de-oxo-bisubstitution, dimercapto-de-oxo-bisubstitution, and carbonyl-trithiane transformation**



13 **14** **15** **16**

The addition of H_2S to an aldehyde or ketone can result in a variety of products. The most usual product is the trithiane **16**.[183] *gem*-Dithiols (**15**) are much more stable than the corresponding hydrates or α-hydroxy thiols.[184] They have been prepared by the treatment of ketones with H_2S under pressure[185] and under mild conditions with HCl as a catalyst.[186] A much more useful application is the addition of thiols to aldehydes and ketones to give hemi-mercaptals [CH(OH)SR] and dithioacetals [$CH(SR)_2$] (Reaction **16-5**). This reaction is generally not a good route to thioketones (**14**). α-Hydroxythiols (**13**) can be prepared from polychloro and polyfluoro aldehydes and ketones.[187] Apparently *gem*-hydroxy thiols (e.g., **13**) are rather unstable and quite difficult to prepare.

Thiols add to aldehydes and ketones to initially give hemi-mercaptals and dithioacetals. Hemi-mercaptals are ordinarily unstable,[188] but they are usually more stable than the corresponding hemiacetals and can be isolated in certain cases.[189] The isolated product of this reaction is most often the dithioacetal, which like the acetals obtained by reaction with an alcohol, are stable in the presence of base. However, a sufficiently strong base can remove a proton from the carbon between the sulfur atoms (—S—CHR—S—)[190] to form the corresponding carbanion (see Reaction **10-71**). The pK_a of such protons is typically 31–37,[191] requiring a strong base, and deprotonation is often quite slow. The reaction of aldehydes or ketones with thiols most commonly uses a Lewis acid catalyst (e.g., boron trifluoride etherate, $BF_3{\cdot}OEt_2$)[192] to give the dithioacetal[193] or dithioketal. Dithioacetals can also be prepared from aldehydes or ketones by treatment with thiols in the presence of $TiCl_4$,[194] $SiCl_4$,[195] $LiBF_4$,[196] $Al(OTf)_3$,[197] tosic acid on silica gel in dichloromethane,[198]

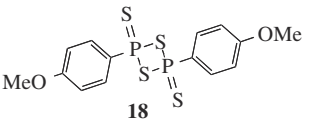
and oxalic acid promotes the reaction.[199] Similarly reactions that use 1,2-ethanedithiol or 1,3-propanedithiol lead to 1,3-dithiolanes (**17**)[200] or 1,3-dithianes.[201] 3-(1,3-Dithian-2-ylidene)pentane- 2,4-dione has been used as a thioacetalization reagent for reactions in water.[202]

17

Dithioacetals and dithioketals are used as protecting groups for aldehydes and ketones, and after subsequent reactions involving the R or R′ group, deprotection regenerates the carbonyl.[203] Simple hydrolysis is the most common method for converting thiocarbonyls to carbonyls, but there are a variety of reagents for this conversion.[204] Lewis acids (e.g., aluminum chloride, $AlCl_3$) and mercuric salts are common reagents (the *Corey–Seebach procedure*).[205] Other reagents include $BF_3{\cdot}OEt_2$ in aq THF containing mercuric oxide (HgO),[206] ceric ammonium nitrate $[Ce(NH_4)_2(NO_3)_6]$,[207] chlorotrimethylsilane and H_2O_2,[208] $PhI(OAc)_2$ in aq acetone,[209] and Cu salts.[210] When aldehydes and ketones react with mercapto–alcohols, mixed acetals or ketals are formed.



Thioamides are converted to amides with *Caro's acid* (H_2SO_5) on SiO_2.[211] The use of 2-mercaptoethanol ($HSCH_2CH_2OH$), for example, leads to an oxathiolane[212] and 3-mercaptopropanol ($HSCH_2CH_2CH_2OH$) leads to an oxathiane. Alternatively, the dithioketal can be desulfurized with Raney nickel (Reaction **14-27**), giving the overall conversion C=O → CH_2 (Reaction **19-70**).

Thioketones (**14**) can be prepared from certain ketones (e.g., diaryl ketones) by treatment with H_2S and an acid catalyst, usually HCl. They are often unstable and usually trimerize (to **16**) or react with air. Thioaldehydes[213] are even less stable and simple ones[214] apparently have never been isolated, although *tert*-BuCHS has been prepared in solution, where it exists for several hours at 20 °C.[215] A high-yield synthesis of thioketones involves

treatment of acyclic[216] ketones with 2,4-bis(4-methoxyphenyl)-1,3,2,4-dithiadiphosphetane-2,4-disulfide[217] (**18**, known as *Lawesson's reagent*).[218] Thioketones can also be prepared by treatment of ketones with P_4S_{10},[219] P_4S_{10} and hexamethyldisiloxane,[220] P_4S_{10} on alumina,[221] and from oximes or various types of hydrazone (overall conversion C=N–→ C=S).[222] Reagent **18** converts the C=O groups of amides and carboxylic esters[223] to C=S groups.[224] Lactones react with **18** in the presence of hexamethyldisiloxane an microwave irradiation to give the thiolactone.[225]

Other reagents may be used for this transformation including $POCl_3$ followed by $S(TMS)_2$, which converts lactams to thiolactams.[226] Treatment with triflic anhydride, and then H_2S[227] or aq $S(NH_4)_2$[228] converts amides to thioamides, as does the microwave assisted reaction with $PSCl_2/H_2O/Et_3N$, without solvent.[229] Carboxylic acids (RCOOH) can be converted directly to dithiocarboxylic esters (RCSSR′),[230] in moderate yield, with P_4S_{10} and a primary alcohol (R′OH).[231]

18

If an aldehyde or ketone possesses an α hydrogen, it can be converted to the corresponding enol thioether (**19**) by treatment with a thiol in the presence of $TiCl_4$.[232] Aldehydes and ketones have been converted to sulfides by treatment with thiols and pyridine–borane, $RCOR' + R^2SH \rightarrow RR'CHSR^2$,[233] in a reductive alkylation reaction, analogous to Reaction **16-7**.

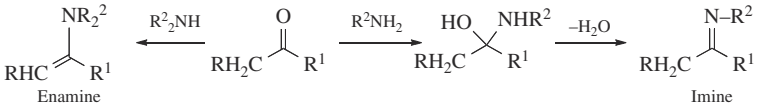
16-12 Formation of Bisulfite Addition Products

O-Hydro-*C*-sulfonato-addition



Bisulfite addition products are formed from aldehydes, methyl ketones, cyclic ketones (generally seven-membered and smaller rings), α-keto esters, and isocyanates, upon treatment with sodium bisulfite ($NaHSO_3$). Most other ketones do not undergo the reaction, probably for steric reasons. The reaction is reversible (by treatment of the addition product with either acid or base)[234] and is useful for the purification of the starting compounds, since the addition products are soluble in water and many of the impurities are not.[235]

OS **I**, 241, 336; **III**, 438; **IV**, 903; **V**, 437.

D. Attack by NH_2, NHR, or NR_2 (Addition of NH_3, RNH_2, R_2NH)

16-13 The Addition of Amines to Aldehydes and Ketones

Alkylimino-de-oxo-bisubstitution

The addition of ammonia[236] to aldehydes or ketones does not generally give useful products. According to the pattern followed by analogous nucleophiles, the initial products would be expected to be *hemiaminals*,[237] but these compounds are generally unstable. In addition, many imines with a hydrogen on the nitrogen spontaneously polymerize.[238]

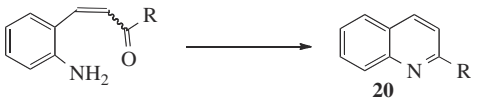
In contrast to ammonia, primary, secondary, and tertiary amines can add to aldehydes[239] and ketones to give different kinds of products. Primary amines give imines[240] and secondary amines give enamines (for reactions, see **10-69**). Such imines are stable enough for isolation, but in some cases, especially with simple R groups, they rapidly decompose

[234] For cleavage with ion-exchange resins, see Khusid, A.Kh.; Chizhova, N.V. *J. Org. Chem. USSR* ***1985,*** *21*, 37. For a discussion of the mechanism, see Young, P.R.; Jencks, W.P. *J. Am. Chem. Soc.* ***1978,*** *100,* 1228.

[235] The reaction has also been used to protect an aldehyde group in the presence of a keto group: Chihara, T.; Wakabayashi, T.; Taya, K. *Chem. Lett.* ***1981***, 1657.

[236] For a review of this reagent in organic synthesis, see Jeyaraman, R. in Pizey, J.S. *Synthetic Reagents*, Vol. 5, Wiley, NY, ***1983***, pp. 9–83.

[237] These compounds have been detected by ^{13}C NMR: Chudek, J.A.; Foster, R.; Young, D. *J. Chem. Soc. Perkin Trans. 2* ***1985***, 1285.



[238] Methanimine $CH_2{=}NH$ is stable in solution for several hours at –95° C, but rapidly decomposes at –80° C: Braillon, B.; Lasne, M.C.; Ripoll, J.L.; Denis, J.M. *Nouv. J. Chim.,* ***1982,*** *6*, 121. See also, Bock, H.; Dammel, R. *Chem. Ber.* ***1987,*** *120*, 1961.

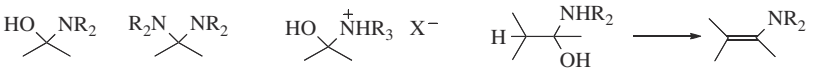
or polymerize unless there is at least one aryl group on the nitrogen or the carbon. When there is an aryl group, the compounds are quite stable. They are usually called *Schiff bases*, and this reaction is the best way to prepare them.[241] Even sterically hindered imines can be prepared.[242] The initial N-substituted hemiaminals[243] lose water to give the stable *Schiff bases*.

In general, ketones react more slowly than aldehydes, and higher temperatures and longer reaction times are often required.[244] In addition, the equilibrium must often be shifted, usually by removal of the water, either azeotropically by distillation, or with a drying agent (e.g., $TiCl_4$),[245] or by addition of a molecular sieve.[246] Imines have been formed from aldehydes and amines in an ionic liquid.[247]



20

The reaction is often used to effect ring closure.[248] The *Friedländer quinoline synthesis*[249] is an example where ortho alkenyl aniline derivatives give the quinoline (**20**).[250] The alkene derivative can be prepared *in situ* from an aldehyde and a suitably functionalized ylid.[251] Pyrylium ions react with ammonia or primary amines to give pyridinium ions[252] (see Reaction **10-57**). Primary amines react with 1,4-diketones, with microwave irradiation, to give N-substituted pyrroles.[253] Similar reactions in the presence of Montmorillonite KSF[254] or by simply heating the components with tosic acid[255] have been reported.

The reaction of secondary amines with ketones leads to enamines (see **10-69**).[256] When secondary amines are added to aldehydes or ketones, the initially formed N,N-disubstituted hemiaminals (**21**) cannot lose water in the same way since the iminium ion intermediate does not have a proton on nitrogen, and in some cases it is possible to isolate them.[257] However, they are generally unstable, and under the reaction conditions usually react further. If no α hydrogen is present, **21** is converted to the more stable *aminal* (**22**).[258]

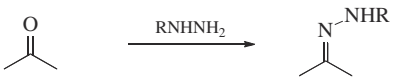
However, if an α hydrogen is present, water (from **21**) or RNH_2 (from **22**) can be lost in that direction to give an enamine (**24**).[259] This is the most common method[260] for the preparation of enamines and usually takes place when an aldehyde

21 **22** (aminal) **23** **24**



or ketone containing an α hydrogen is treated with a secondary amine.[261] The water is usually removed azeotropically or with a drying agent,[262] and molecular sieves can also be used.[263] Silyl carbamates (e.g., $Me_2NCO_2SiMe_3$) have been used to convert ketones to enamines.[264] Stable primary enamines have also been prepared.[265] Enamino–ketones have been prepared from diketones and secondary amines using low-molecular-weight amines in water,[266] or using microwave irradiation on silica gel.[267] Enamines have been prepared by the reaction of an aldehyde, a secondary amine, and a terminal alkyne in the presence of AgI at 100 °C,[268] AgI in an ionic liquid,[269] CuI with microwave irradiation,[270] or a Au catalyst.[271]

Tertiary amines can only give salts (**23**).

16-14 The Addition of Hydrazine Derivatives to Carbonyl Compounds

Hydrazono-de-oxo-bisubstitution

The product of condensation of a hydrazine and an aldehyde or ketone is called a *hydrazone*. Hydrazine itself gives hydrazones only with aryl ketones. With other aldehydes and ketones, either no useful product can be isolated, or the remaining NH_2 group condenses with a second equivalent of carbonyl compound to give an *azine*. This type

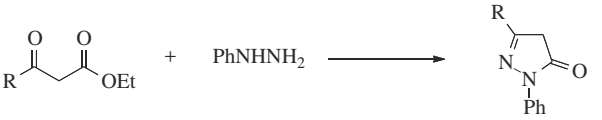
of product is especially important for aromatic aldehydes:

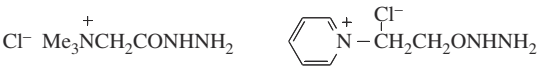
$$ArCH{=}N{-}NH_2 + ArCHO \longrightarrow \underset{\text{An azine}}{ArCH{=}N-N{=}CHAr}$$



However, in some cases azines can be converted to hydrazones by treatment with excess hydrazine and NaOH.[272] Arylhydrazines, especially phenyl, *p*-nitrophenyl, and 2,4-dinitrophenyl,[273] are used much more often and give the corresponding hydrazones with most aldehydes and ketones.[274] Since these are usually solids, they make excellent derivatives and were commonly employed for this purpose in the past, before the advent of modern spectroscopy methods. Cyclic hydrazones are known,[275] as are conjugated hydrazones.[276] Azides react with *N,N*-dimethylhydrazine and ferric chloride to give the *N,N*-dimethylhydrazone.[277] Alkenes react with CO/H_2, phenylhydrazine and a diphosphine catalyst to give a regioisomeric mixture of phenylhydrazones that favored "anti-Markovnikov" addition.[278] Oximes are converted to hydrazones with water and hydrazine in refluxing ethanol.[279]

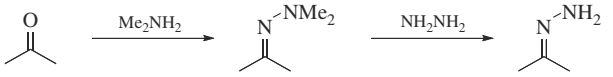
α-Hydroxy aldehydes and ketones and α-dicarbonyl compounds give *osazones*, in which two adjacent carbons have carbon–nitrogen double bonds:

An osazone



Osazones are particularly important in carbohydrate chemistry, and the *osazone test*[280] with phenylhydrazine is used to test for the presence of sugars with an adjacent sterogenic carbon. In contrast to this behavior, β-diketones and β-keto esters give *pyrazoles* and *pyrazolones*, respectively (the latter is illustrated for β-keto esters). No azines are formed under these conditions.

A pyrazolone



Other hydrazine derivatives frequently used to prepare the corresponding hydrazone are semicarbazide ($NH_2NHCONH_2$), in which case the hydrazone is called a semicarbazone: *Girard's reagents T and P* are hydrazones that are water soluble because of the ionic group. Girard's reagents are often used for purification of carbonyl compounds.[281]

16-15 The Formation of Oximes

Hydroxyimino-de-oxo-bisubstitution

In a reaction very much like **16-14**, oximes can be prepared by the addition of hydroxylamine (NH_2OH) to aldehydes or ketones. Derivatives of hydroxylamine [e.g., H_2NOSO_3H and $HON(SO_3Na)_2$] have also been used. For hindered ketones (e.g., 2,2,4,4-tetramethyl-3-pentanone), high pressures (as high as 10,000 atm) may be necessary.[283] The reaction of hydroxylamine with unsymmetrical ketones or with aldehydes leads to a mixture of (*E*)- and (*Z*)-isomers. For aromatic aldehydes, heating with K_2CO_3 led to the (*E*)- isomer, whereas heating with $CuSO_4$ gave the (*Z*)-hydroxylamine.[284] Hydroxylamines react with ketones in ionic liquids[285] and on silica gel.[286]

It has been shown[287] that the rate of formation of oximes is at a maximum at a pH that depends on the substrate but is usually ~ 4. The rate also decreases as the pH is either raised or lowered from this point (a bell-shaped curve). In Section 16.A.i, bell-shaped curves like this were shown to be caused by changes in the rate-determining step in many cases. In this case, at low pH values step 2 is rapid (because it is acid catalyzed), and

25

step 1 is slow (and rate determining), because under these acidic conditions most of the NH_2OH molecules have been converted to the conjugate $^+NH_3OH$ ions, which cannot attack the substrate. As the pH is slowly increased, the fraction of free NH_2OH molecules increases and consequently so does the reaction rate, until the maximum rate is reached at ~ pH 4. As the rising pH causes an increase in the rate of step 1, it also causes a *decrease* in

the rate of the acid-catalyzed step 2, although this latter process has not affected the overall rate since step 2 was still faster than step 1. However, when the pH goes above ~ 4, step 2 becomes rate determining, and although the rate of step 1 is still increasing (as it will until essentially all the NH_2OH is unprotonated), it is now step 2 that determines the rate. This step is slowed by the decrease in acid concentration. Thus the overall rate decreases as the pH rises beyond ~ 4. It is likely that similar considerations apply to the reaction of aldehydes and ketones with amines, hydrazines, and other nitrogen nucleophiles.[288] There is evidence that when the nucleophile is 2-methylthiosemicarbazide, there is a second change in the rate-determining step: > pH ~ 10 *basic* catalysis of step 2 has increased the rate of this step to the point where step 1 is again rate determining.[289] Still a third change in the rate-determining step has been found at ~ pH 1, showing that at least in some cases step 1 actually consists of two steps: formation of a zwitterion (e.g., $HOH_2N^+—C—O^-$ in the case shown above) and conversion of this to **25**.[290] The intermediate **25** has been detected by NMR in the reaction between NH_2OH and acetaldehyde.[291]

16-16 The Conversion of Aldehydes to Nitriles

Nitrilo-de-hydro,oxo-tersubstitution

Aldehydes can be converted to nitriles in one step by treatment with hydroxylamine hydrochloride and either formic acid,[292] $KF—Al_2O_3$,[293] or $NaHSO_4{\cdot}SiO_2$ with microwave irradiation.[294] Heating in *N*-methylpyrrolidinone (NMP) is also effective with aryl aldehydes[295] and heating on dry alumina with aliphatic aldehyde.[296] The reaction is a combination of **16-15** and **17-29**. Direct nitrile formation has also been accomplished with certain derivatives of NH_2OH, notably, NH_2OSO_2OH.[297] Treatment with hydroxylamine and NaI[298] or certain carbonates[299] also converts aldehydes to the nitrile. Another method involves treatment with hydrazoic acid, although the *Schmidt reaction* (**18-16**) may compete.[300] Microwave irradiation has been used with $NH_2OH{\cdot}HCl$ and another reagent, which includes phthalic anhydride[301] or H—Y zeolite.[302] The reaction of an aldehyde with hydroxylamine followed by diethyl

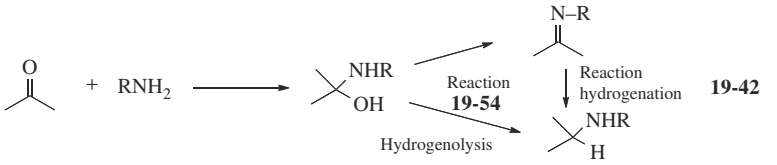
cholorophosphate ($EtOPOCl_2$) gives the nitrile.[303] Heating with hydroxylamine in DMSO[304] and using hydroxylamine and oxalyl chloride[305] have been used. *tert*-Butanesulfinyl imines are also used for the conversion of aldehydes to nitriles.[306] Other reagents include trimethylsilyl azide,[307] hydroxylamine hydrochloride/$MgSO_4$/TsOH,[308] or I_2 with aq ammonia,[309] The reaction of a conjugated aldehyde with ammonia, CuCl, and 50% H_2O_2 gave the conjugated nitrile.[310] Aldehydes with IBX (*o*-iodoxybenzoic acid) and liquid ammonia gives the nitrile.[311] Tetrabutylammonium tribromide in aq ammonia has also been used.[312] Trichloroisocyanuric acid with a catalytic amount of TEMPO (Sec. 5.C.i) converts aldehydes to nitriles at 0 °C in dichloromethane.[313] Aromatic aldehydes are converted to the nitrile by heating 2.2 molar equivalents of $NaN(SiMe_3)_2$ in 1,3-dimethylimidazolidin-2-one, in a sealed tube.[314] The aldehydes employed had a hydroxy substituent.

In a related reaction, the reaction of primary alcohols with iodine in ammonia water gives the corresponding nitrile.[315] Upon treatment with 2 molar equivalents of dimethylaluminum amide (Me_2AlNH_2), carboxylic esters give nitriles: $RCO_2R' \rightarrow RCN$.[316] This is likely a combination of Reaction **16-75** and **17-30** (see Reaction **19-5**).

OS **V**, 656.

16-17 Reductive Alkylation of Ammonia or Amines



Hydro,dialkylamino-de-oxo-bisubstitution

When an aldehyde or a ketone is treated with ammonia or a primary or secondary amine in the presence of hydrogen gas and an appropriate catalyst (e.g., Rh or Ir; heterogeneous or homogeneous),[317] *reductive alkylation* of ammonia or the amine (or *reductive amination* of the carbonyl compound) takes place.[318] The reaction can formally be regarded as occurring in the following manner (shown for a primary amine), which probably does correspond to the actual sequence of steps:[319] In this regard, the reaction of an aldehyde

with an amine to give an iminium salt (**16-31**) can be followed in a second chemical step of reduction of the C=N unit (**19-42**) using $NaBH_4$ or a variety of other reagents.[320]

Primary amines have been prepared from many aldehydes with at least five carbons and from many ketones by treatment with ammonia and a reducing agent. Smaller aldehydes are usually too reactive to permit isolation of the primary amine. Secondary amines have been prepared by both possible procedures: 2 molar equivalents of ammonia and 1 molar equivalent of aldehyde or ketone, and 1 molar equivalent of primary amine and 1 molar equivalent of carbonyl compound, the latter method being better for all but aromatic aldehydes. Tertiary amines can be prepared in three ways. In general, they are prepared from primary or secondary amines.[321] The method is seldom carried out with 3 molar equivalents of ammonia and 1 molar equivalent of carbonyl compound. When the reagent is ammonia, it is possible for the initial product to react again and for this product to react again, so that secondary and tertiary amines are usually obtained as side products. Similarly, primary amines give tertiary as well as secondary amines. In order to minimize this, the aldehyde or ketone is treated with an excess of ammonia or primary amine (unless of course the higher amine is desired).

For ammonia and primary amines there are two possible pathways, but when secondary amines are involved, only the hydrogenolysis pathway is possible. The reaction is compatible with amino acids, giving the N-alkylated amino acid.[322] Other reducing agents[323] can be used instead of hydrogen and a catalyst, among them boranes,[324] $PhSiH_3$ with 2% Bu_2SnCl_2,[325] triethylsilane with an Ir[326] or an In catalyst,[327] zinc and HCl, or Zn (with formaldehyde for reductive methylation),[328] and polymethylhydrosiloxane.[329] Several hydride reducing agents can be used, including

$NaBH_4$,[330] $NaBH_4$ with $Ti(OiPr)_4$[331] or $NiCl_2$,[332] $NaBH_4/H_3BO_4$,[333] BER,[334] polymer-bound triethylammonium acetoxyborohydride,[335] $LiBH_4$,[336] $ZnBH_4$-*N*-methylpiperidine,[337] $ZrBH_4$,[338] $NaBH_3CN$,[339] or sodium triacetoxyborohydride,[340] Aldehydes and primary amines react with allylic halides, in the presence of Zn dust, to give a homoallylic secondary amine.[341] A *Hantzsch dihydropyridine* in conjunction with a Sc catalyst has been used,[342] and the use of a *Hantzsch ester* in a reductive amination is sometimes called a hydrogen-bond catalyzed reaction.[343] The reaction of an aldehyde and an amine in isopropyl alcohol, in the presence of Ni nanoparticles, undergoes reductive amination via hydrogen transfer.[344]

Formic acid is an effective reagent for reductive amination[345] in what is called the *Wallach reaction*. Secondary amines react with formaldehyde and NaH_2PO_3 to give the N-methylated tertiary amine[346] and microwave irradiation has also been used.[347] Conjugated aldehydes are converted to alkenyl-amines with the amine/silica gel followed by reduction with zinc borohydride.[348] In the particular case where primary or secondary amines are reductively methylated with formaldehyde and formic acid, the method is called the *Eschweiler–Clarke procedure*. Heating with paraformaldehyde and oxalyl chloride has been used to give the same result.[349] It is possible to use ammonium (or amine) salts of formic acid,[350] or formamides, as a substitute for the *Wallach conditions*. This method is called the *Leuckart reaction*,[351] and in this case the products obtained are often the *N*-formyl derivatives of the amines instead of the free amines. A Rh catalyzed variation has been reported.[352]

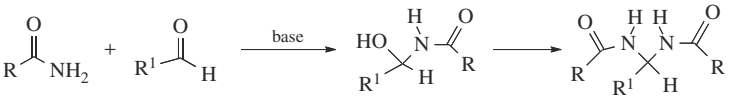
Allylic silanes react with aldehydes and carbamates, in the presence of Bi catalysts,[353] or BF_3·OEt_2[354] to give the corresponding allylic *N*-carbamoyl derivative. The reaction can be done with aromatic amines in the presence of vinyl ethers and a Cu complex to give β-amino ketones.[355] Reductive amination of an aryl amine and an aryl aldehyde that contains an ortho conjugated ketone substituent gives the amine, which adds 1,4- (Reaction **15-AA**) to the α,β-unsaturated ketone unit to give a bicyclic amine.[356] Alternative methods of reductive alkylation have been developed. Alkylation of an imine formed *in situ* is also possible.[357]



Enantioselective reductive amination reactions are known, generating chiral amines. Ketones and anilines react in the presence of an organocatalyst and a catalytic amount of a chiral phosphoric acid to give the chiral amine.[358] The reaction of an aldehyde with a chiral amine initiated a reaction that gave a chiral primary amine.[359] A Yb catalyzed reaction with a ketone gave a chiral secondary amine.[360] Aldehydes react with *N*-diphenylphosphinoylimines and Et_2Zn, in the presence of a chiral Cu precatalyst, to give a chiral amine.[361] Asymmetric biocatalytic reductive amination reactions are known.[362] Asymmetric reductive amination has been attempted using a *Hantzsch ester* mediated reaction.[363]

Reductive alkylation has also been carried out on nitro, nitroso, azo, and other compounds that are reduced *in situ* to primary or secondary amines. Azo compounds react with aldehydes, in the presence of proline, and subsequent reduction with $NaBH_4$ gives the chiral hydrazine derivative.[364]

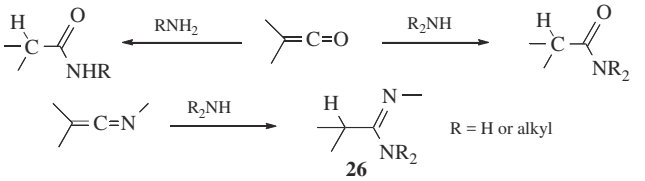
16-18 Addition of Amides to Aldehydes

Alkylamido-de-oxo-bisubstitution



Amides can add to aldehydes in the presence of bases (so the nucleophile is actually $RCONH^-$) or acids to give acylated amino alcohols, which often react further to give alkylidene or arylidene bisamides.[365] If the R′ group contains an α hydrogen, water may split out.

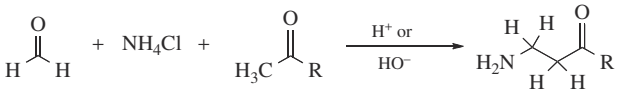
Sulfonamides add to aldehydes to give the *N*-sulfonyl imine. Benzaldehyde reacts with $TsNH_2$ (e.g., with trifluoroacetic anhydride, TFAA) in CH_2Cl_2 at reflux,[366] or with $TiCl_4$ in refluxing dichloroethane,[367] to give the *N*-tosylimine (Ts—N=CHPh). In a similar manner, the reaction of $TolSO_2Na$ + $PhSO_2Na$ with an aldehyde in aq formic acid gives the *N*-phenylsulfonyl imine.[368] The reaction of an aldehyde with Ph_3P=NTs and a ruthenium catalyst gives the *N*-tosyl imine.[369]



Primary and secondary amines add to ketenes to give, respectively, *N*-substituted and *N, N*-disubstituted amides:[370] and to ketenimines to give amidines, (**26**).[371]

26

16-19 The Mannich Reaction

Acyl,amino-de-oxo-bisubstitution, and so on

In the *Mannich reaction*, formaldehyde (or sometimes another aldehyde) is condensed with ammonia, in the form of its salt, and a compound containing an active hydrogen.[372] This can formally be considered as an addition of ammonia to give H_2NCH_2OH, followed by a nucleophilic substitution. The reaction can be carried out with salts of primary or secondary amines,[373] or with amides[374] rather than ammonia, in which cases the product is substituted on the nitrogen with R, R^2, and RCO, respectively. The product is referred to as a *Mannich base*. The imine can be generated *in situ*, and the reaction of a ketone, formaldehyde, and diethylamine with microwave irradiation gave the *Mannich* product, a β-amino ketone.[375] Many active hydrogen compounds give the reaction, including ketones and aldehydes, esters, nitroalkanes,[376] and nitriles as well as ortho-carbon atoms of phenols, the carbon of terminal alkynes, the oxygen of alcohols and the sulfur of thiols.[377]

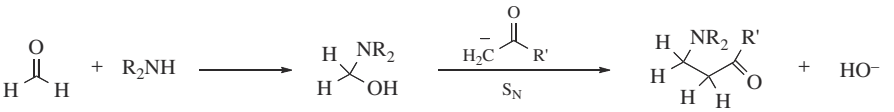
Arylamines do not normally give the reaction, but hydrazines can be used.[378] Vinylogous *Mannich reactions* are known[379] (see Sec. 6.B for vinylogy).

The *Mannich base* product can react further in three ways. If it is a primary or secondary amine, it may condense with one or two additional molecules of aldehyde and an active compound, for example,

$$H_2NCH_2CH_2COR \xrightarrow[CH_3COR]{HCHO} HN(CH_2CH_2COR)_2 \xrightarrow[CH_3COR]{HCHO} N(CH_2CH_2COR)_3$$

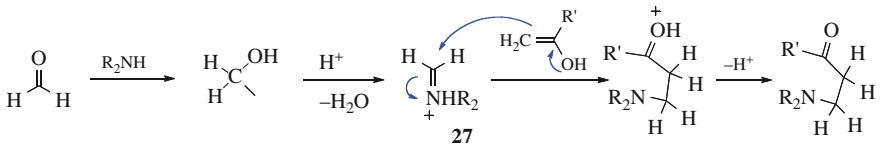
If the active hydrogen compound has two or three active hydrogen atoms, the *Mannich base* may condense with one or two additional molecules of aldehyde and ammonia or amine, for example,

$$H_2NCH_2CH_2COR \xrightarrow[NH_3]{HCHO} (H_2NCH_2)_2CHCOR \xrightarrow[NH_3]{HCHO} (H_2NCH_2)_3CHCOR$$



Another reaction consists of condensation of the *Mannich base* with excess formaldehyde:

$$H_2NCH_2CH_2COR + HCHO \longrightarrow H_2C{=}NCH_2CH_2COR$$

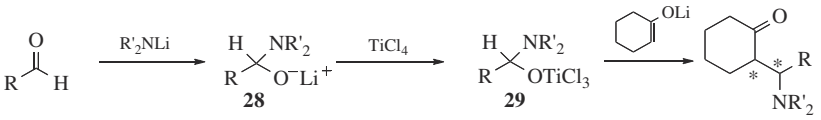


Sometimes it is possible to obtain these products of further condensation as the main products of the reaction. At other times, they are side products.

When the *Mannich base* contains an amino group β to a carbonyl (and it usually does), ammonia is easily eliminated. This is a route to α,β-unsaturated aldehydes, ketones, esters, and so on.

Studies of the reaction kinetics have led to the following proposals for the mechanism of the *Mannich reaction*.[380] The base-catalyzed reaction:

The acid-catalyzed reaction:



According to this mechanism, it is the free amine, not the salt that reacts, even in acid solution; and the active-hydrogen compound (in the acid-catalyzed process) reacts as the enol when that is possible. This latter step is similar to what happens in Reaction **12-4**. There is kinetic evidence for the intermediacy of the iminium ion (**27**).[381]

When an unsymmetrical ketone is used as the active-hydrogen component, two products are possible. Regioselectivity has been obtained by treatment of the ketone with

preformed iminium ions:[382] the use of $Me_2N^+{=}CH_2$ CF_3COO^- in CF_3COOH gives substitution at the more highly substituted position, while with $(i\text{Pr})_2N^+{=}CH_2$ ClO_4^- the reaction takes place at the less highly substituted position.[383] The preformed iminium compound dimethyl(methylene)ammonium iodide ($CH_2{=}N^+Me_2$ I^-), called an *Eschenmoser's salt*,[384] has also been used in *Mannich reactions*.[385] The analogous chloride salt has been condensed with an imine to give a β,β′-dimethylamino ketone after acid hydrolysis.[386]

Another type of preformed reagent (**29**) has been used to carry out diastereoselective *Mannich reactions*. The lithium salts (**28**) are treated with $TiCl_4$ to give **29**, which is then treated with the enolate anion of a ketone.[387] The Pd catalyzed Mannich reaction of enol ethers to imines is also known.[388] The reaction of silyl enol ethers and imines[389] is catalyzed by HBF_4 in aq methanol.[390] Similarly, silyl enol ethers react with aldehydes and aniline in the presence of $InCl_3$ to give the β-amino ketone.[391]

Enantioselective *Mannich reactions* are known.[392] Chiral catalysts are commonly used,[393] including proline,[394] proline derivatives, or proline analogues,[395] a Pybox-La catalyst,[396] chiral aminosulfonamides,[397] or Cinchona alkaloids,[398] and other chiral amines.[399] Chiral

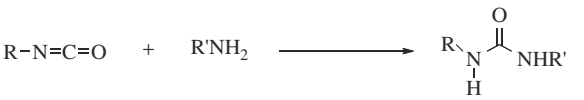
Brønsted acids are also used as catalysts,[400] as well as chiral ammonium salts.[401] Chiral diamine[402] or phosphine-imine[403] ligands have been used, and chiral dinuclear zinc compounds.[404] Chiral auxiliaries on the carbonyl fragment can be used.[405] Chiral imines, in the form of chiral hydrazones, have been used with silyl enol ethers and a Sc catalyst.[406] Chiral amines react with aldehydes, with silyl enol ethers and an $InCl_3$ catalyst in ionic liquids, to give the *Mannich* product with good enantioselectivity.[407] A chiral thiourea catalyst has been used with a vinylogous *Mannich reaction*[408] (see Sec. 6.B for vinylogy).



The reaction of nitroalkanes and amines, usually in the presence of a metal catalyst (e.g., CuBr), [409] has been called the nitro-*Mannich reaction*.[410] An asymmetric nitro-*Mannich reaction* used a Cu—Sm catalyst,[411] a Cu catalyst,[412] or a chiral thiourea catalyst.[413]

16-20 The Addition of Amines to Isocyanates

***N*-Hydro-*C*-alkylamino-addition**

Ammonia and primary and secondary amines can be added to isocyanates[414] to give substituted ureas.[415] Isothiocyanates give thioureas.[416] This is an excellent method for the preparation of ureas and thioureas. These compounds are often used as derivatives for primary and secondary amines. Isocyanic acid (HNCO) also gives the reaction; usually its salts (e.g., NaNCO) are used. Wöhler's famous synthesis of urea involved the addition of ammonia to a salt of this acid.[417]

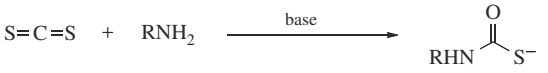
16-21 The Addition of Ammonia or Amines to Nitriles

N-Hydro-*C*-amino-addition

Unsubstituted amidines (in the form of their salts) can be prepared by addition of ammonia to nitriles.[418] Many amidines have been made in this way. Dinitriles of suitable chain length can give imidines (**30**).[419]

30



Primary and secondary amines can be used instead of ammonia, to give substituted amidines, but only if the nitrile contains electron-withdrawing groups; for example, Cl_3CCN gives the reaction. Ordinary nitriles do not react, and, in fact, acetonitrile is often used as a solvent in this reaction.[420] Ordinary nitriles can be converted to amidines by treatment with an alkylchloroaluminum amide [$MeAl(Cl)NR_2$; R = H or Me).[421] The addition of ammonia to cyanamide (NH_2CN) gives guanidine [$(NH_2)_2C{=}NH$]. Guanidines can also be formed from amines.[422]

If water is present, in the presence of a Ru[423] or a Pt catalyst,[424] the addition of a primary or secondary amine to a nitrile gives an amide: $RCN + R^1NHR^2 + H_2O \rightarrow RCONR^1R^2 + NH_3$ (R^2 may be H). When benzonitrile reacts with $H_2PO_3Se^-$ in aq methanol, a selenoamide [$Ph(C{=}Se)NH_2$], is formed after treatment with aq potassium carbonate.[425]

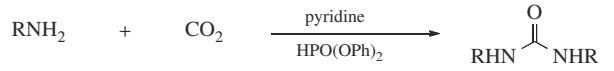
16-22 The Addition of Amines to Carbon Disulfide and Carbon Dioxide



S-Metallo-*C*-alkylamino-addition

Salts of dithiocarbamic acid can be prepared by the addition of primary or secondary amines to carbon disulfide.[426] This reaction is similar to **16-10**. Hydrogen sulfide can be eliminated from the product, directly or indirectly, to give isothiocyanates (RNCS). Isothiocyanates can be obtained directly by the reaction of primary amines and CS_2 in

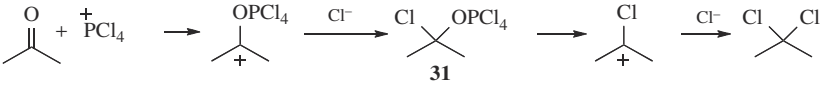
E. Halogen Nucleophiles

16-23 The Formation of *gem*-Dihalides from Aldehydes and Ketones



Dihalo-de-oxo-bisubstitution

Aliphatic aldehydes and ketones can be converted to *gem*-dichlorides[432] by treatment with PCl_5. The reaction fails for perhalo ketones.[433] If the aldehyde or ketone has an α hydrogen, elimination of HCl may follow and a vinylic chloride is a frequent side product, as shown,[434] or even the main product.[435] Phosphorus pentabromide (PBr_5) does not give good yields of *gem*-dibromides,[436] but these can be obtained from aldehydes, by the use of Br_2, and triphenyl phosphite.[437] *gem*-Dichlorides can be prepared by reacting an aldehyde with $BiCl_3$.[438]

The mechanism of *gem*-dichloride formation involves initial attack on PCl_4^+, which is present in solid PCl_5, by the carbonyl oxygen, followed by addition of Cl^- to the carbon:[439]

This chloride ion may come from PCl_6^-, which is also present in solid PCl_5. There follows a two-step S_N1 process. Alternatively, **31** can be converted to the product without going through the chlorocarbenium ion, by an S_Ni process.

This reaction has sometimes been performed on carboxylic esters, though these compounds very seldom undergo any addition to the C=O bond. An example is the conversion of $F_3CCOOPh$ to F_3CCCl_2OPh.[440] However, formates commonly give the reaction.

Many aldehydes and ketones have been converted to *gem*-difluoro compounds with sulfur tetrafluoride (SF_4),[441] including quinones, which give 1,1,4,4-tetrafluorocyclohexadiene derivatives. With ketones, yields can be raised and the reaction temperature lowered, by the addition of anhydrous HF.[442] Carboxylic acids, acyl chlorides, and amides react with SF_2 to give 1,1,1-trifluorides. In these cases, the first product is the acyl fluoride, which then undergoes the *gem*-difluorination reaction:

The acyl fluoride can be isolated. Carboxylic esters also give trifluorides, but more vigorous conditions are required. In this case, the carbonyl group of the ester is attacked first, and RCF_2OR' can be isolated from RCO_2R'[443] and then converted to the trifluoride. Anhydrides can react in either manner. Both types of intermediate are isolable under the right conditions, and SF_4 even converts CO_2 to CF_4. A disadvantage of reactions with SF_4 is that they require a pressure vessel lined with stainless steel. Selenium tetrafluoride (SeF_4) gives similar reactions, but atmospheric pressure and ordinary glassware can be used.[444] Another reagent that is often used to convert aldehydes and ketones to *gem*-difluorides is the commercially available diethylaminosulfur trifluoride (**DAST**, Et_2NSF_3), and CF_2Br_2 in the presence of zinc.[445] The mechanism with SF_4 is probably similar in general nature, if not in specific detail, to that with PCl_5. Some dithianes can be converted to *gem*-difluorides with a mixture of fluorine and iodine in acetonitrile.[446] Oximes give *gem*-difluorides with $NO^+BF_4^-$ and pyridinium polyhydrogen fluoride.[447]

Treatment with hydrazine to give the hydrazone, and then $CuBr_2$/*t*-BuOLi, generated the *gem*-dibromide.[448] Oximes give *gem*-dichlorides upon treatment with chlorine and $BF_3{\cdot}OEt_2$, and then HCl.[449]

In a related process, α-halo ethers can be prepared by treatment of aldehydes and ketones with an alcohol and HX. The reaction is applicable to aliphatic aldehydes and ketones and to primary and secondary alcohols. The addition of HX to an aldehyde or

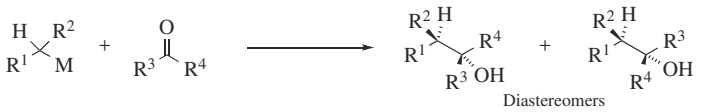
F. Attack at Carbon by Organometallic Compounds[451]

16-24 The Addition of Grignard Reagents and Organolithium Reagents to Aldehydes and Ketones

***O*-Hydro-*C*-alkyl-addition**



Organomagnesium compounds, commonly known as *Grignard reagents* (RMgX), are formed by the reaction of alkyl, vinyl, or aryl halides with magnesium metal, usually in ether solvents (e.g., diethyl ether or THF; Reaction **12-38**). Halogen–Mg exchange can generate a *Grignard reagent* by reaction of aryl halides with reactive aliphatic *Grignard reagents*.[452] Microwave irradiation has been used to facilitate the formation of *Grignard reagents* from aryl chlorides that are slow to react otherwise.[453]

The addition of *Grignard reagents* to aldehydes and ketones[454] is known as the *Grignard reaction.*[455] The initial product of reaction with a carbonyl is a magnesium alkoxide, requiring a hydrolysis step to generate the final alcohol product. Formaldehyde gives primary alcohols; other aldehydes give secondary alcohols; and ketones give tertiary alcohols. The reaction is of very broad scope. In many cases, the hydrolysis step is carried out with dilute HCl or H_2SO_4, but this cannot be done for tertiary alcohols in which at least one R group is alkyl because such alcohols are easily dehydrated under acidic conditions (Reaction **17-1**). In such cases (and often for other alcohols as well), an aqueous solution of ammonium chloride is used instead of a strong acid. *Grignard reagents* have been used in solid-phase synthesis.[456] Ionic liquids have been used for the *Grignard reaction*.[457]

Transition metal catalysts can promote 1,2-addition of Grignard reagents to ketones. A catalytic amount of Zn(II) compounds promote the reaction, for example.[458] In the presence of a catalytic amount of $InCl_3$, *Grignard reagents* react to give a mixture of 1,2- and 1,4-addition products with the 1,4-product predominating, but there was an increased 1,2-addition relative to the uncatalyzed reaction.[459]

Diastereoselective addition[460] has been carried out with achiral reagents and chiral substrates,[461] similar to the reduction shown in Reaction **19-36**.[462] Because the attacking atom in this case is carbon, diastereoselective addition is possible with an achiral substrate and an optically active reagent.[463] The use of suitable reactants creates, in the most general case, two new stereogenic centers, so the product can exist as two pairs of enantiomers, as shown. Even if the organometallic compound is racemic, it still may be possible to get a diastereoselective reaction; that is, one pair of enantiomers is formed in greater amount than the other.[464]

Asymmetric *Grignard reactions* are possible under certain circumstances.[465] Chiral ligands with a chiral Cu catalyst[466] or a chiral Ti complex[467] give alcohols with good enantioselectivity. An interesting method formed using an alkylmagnesium halide, dibutylmagnesium (Bu_2Mg) and a chiral diamine, and subsequent reaction with an aldehyde led to the alcohol derived from acyl addition of a butyl group with good enantioselectivity.[468] N-Heterocyclic carbenes have been used as organocatalysts for asymmetric *Grignard reactions*.[469] Aryl iodides undergo halogen–magnesium exchange when pretreated with PhMgCl, and subsequent reaction with an aldehyde gives the alcohol.[470]

The reaction of aldehydes or ketones with alkyl and aryl *Grignard reagents* was done in the earliest work without preliminary formation of RMgX, by mixing RX, the carbonyl compound, and magnesium metal in an ether solvent. This approach preceded Grignard's work, and is now known as the *Barbier reaction*.[471] The organolithium analogue of this process is also known.[472] Yields were generally satisfactory. Carboxylic ester, nitrile, and imide groups in the R are not affected by the reaction conditions.[473] Modern versions of the

Barbier reaction employ other metals and/or reaction conditions, and will be discussed in Reaction **16-25**. However, Mg–*Barbier reactions* are catalyzed by other metal complexes (e.g., Cu compounds).[474] Some transition metal compounds are stable in water, so some *Grignard–Barbier reactions* can be done in water.[475] A retro-*Barbier reaction* has been reported in which a cyclic tertiary alcohol was treated to an excess of bromine and potassium carbonate to give 6-bromo-2-hexanone from 1-methylcyclopentanol.[476]

The reaction of RMgX or RLi with α,β-unsaturated aldehydes or ketones can proceed via 1,4-addition as well as normal 1,2-addition (see *Michael addition* in Reaction **15-25**).[477] In general, alkyllithium reagents give less 1,4 addition than the corresponding *Grignard reagents*.[478] In a compound containing both an aldehyde and a ketone, it is possible to add RMgX chemoselectively to the aldehyde without significantly disturbing the carbonyl of the ketone group[479] (see also, Reaction **16-24**). *Grignard reagents* have been shown to add to some conjugated cyclic ketones with an α,β-OTf group via 1,2-addition, followed by cleavage to give an alkynyl ketone.[480]

In some cases, a *Grignard reaction* can be performed intramolecularly.[481] For example, treatment of 5-bromo-2-pentanone with magnesium and a small amount of mercuric chloride in THF produced 1-methyl-1-cyclobutanol in 60% yield.[482] Other four- and five-membered ring compounds were also prepared by this procedure. Similar closing of five- and six-membered rings was achieved by treatment of a δ- or ε-halocarbonyl compound, not with a metal, but with a dianion derived from nickel tetraphenyporphine[483] (see Reaction 16-25).

The gem-disubstituted Mg compounds formed from CH_2Br_2 or CH_2I_2 (Reaction **12-38**) react with aldehydes or ketones to give alkenes in moderate-to-good yields.[484] *Wittig-type reactions* also produce alkenes and are discussed in Reaction **16-44**. The reaction could not be extended to other *gem*-dihalides. Similar reactions with *gem*-dimetallic compounds prepared with metals other than magnesium also have produced alkenes.[485]

Organolithium reagents (RLi), prepared from alkyl halides and Li metal or by exchange of an alkyl halide with a reactive organolithium (Reaction **12-38**) react with aldehydes and ketones by acyl addition to give the alcohol,[486] after hydrolysis. Organolithium reagents are more basic than the corresponding *Grignard reagent*, which leads to problems of

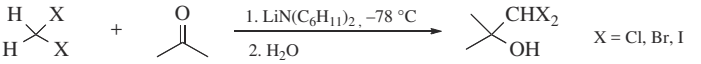
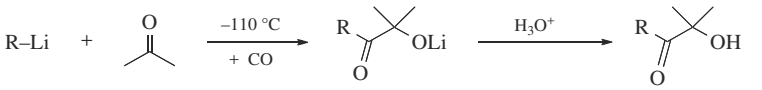
deprotonation in some cases. Organolithium reagents are generally more nucleophilic, however, and can add to hindered ketones with relative ease when compared to the analogous *Grignard reagent*.[487] These reagents tend to form aggregates, which influences the reactivity and selectivity of the addition reaction.[488] The addition of lithium amide–butyllithium mixed aggregates has been studied.[489]

Alkyl, vinyl,[490] and aryl organolithium reagents can be prepared and undergo acyl addition. Structural variations are also possible, including enantioselective 1,2-addition.[491] 1-Bromo-1-lithioethene was prepared, and reacts with an aldehyde to give an allylic alcohol bearing a vinyl bromide unit.[492] An interesting variation of the fundamental acyl addition reaction of organolithium reagents treated an aldehyde with an acyl-lithio amide [LiC(=O)N(Me)CH_2Me] to give an α-hydroxy amide derivative.[493]

As with the reduction of aldehydes and ketones (Reaction **19-36**), the addition of organometallic compounds to these substrates can be carried out enantioselectively and diastereoselectively.[494] Chiral secondary alcohols have been obtained with high enantioselectivity by addition of *Grignard* and organolithium compounds to aromatic aldehydes, in the presence of optically active amino alcohols as ligands.[495]



An interesting variation is the reaction of methyllithium and CH_2I_2 with an aliphatic aldehyde to give an epoxide.[496] A lithio-epoxide was formed by treating an epoxide with *sec*-butyllithium in the presence of sparteine,[497] or with *n*-butyllithium/TMEDA,[498] and subsequent reaction with an aldehyde led to an epoxy alcohol. Alkylidene oxetanes react with lithium, and then with an aldehyde to give a conjugated ketone.[499] The reaction of *gem*-dihalides with a carbonyl compound and Li or BuLi give epoxides[500] (see also, Reaction **16-46**).



In other uses of *gem*-dihalo compounds, aldehydes and ketones add the CH_2I group [$R_2CO \rightarrow R_2C(OH)CH_2I$] when treated with CH_2I_2 in the presence of SmI_2,[501] and the

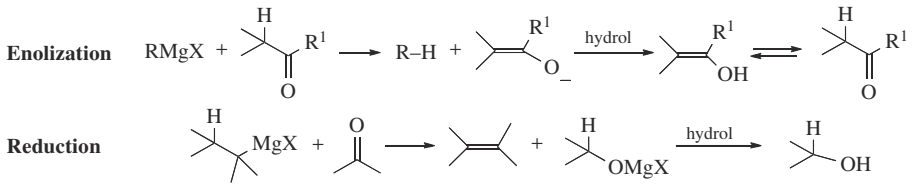
CHX_2 group when treated with methylene halides and lithium dicyclohexylamide at low temperatures.[502]

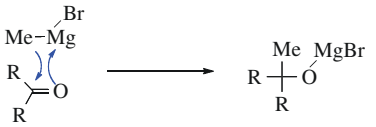


It is possible to add an acyl group to a ketone to give (after hydrolysis) an α-hydroxy ketone.[503] This can be done by adding RLi and CO to the ketone at −110 °C:[504]

When the same reaction is carried out with carboxylic esters ($R'COOR^2$), α-diketones ($RCOCOR'$) are obtained.[503]

Most aldehydes and ketones react with most *Grignard reagents*, but there are several potential side reactions[505] that occur mostly with hindered ketones and with bulky *Grignard reagents*. The two most important of these are *enolization* and *reduction*. The former requires that the aldehyde or ketone have an α hydrogen, and the latter requires that the *Grignard reagent* have a β hydrogen:

Enolization is an acid–base reaction (**12-24**) in which a proton is removed from the α carbon by the *Grignard reagent*, which is a strong base. The carbonyl compound is converted to its enolate anion, which, on hydrolysis, gives the original ketone or aldehyde. Enolization is important not only for hindered ketones but also for those that have a relatively high percentage of enol (e.g., β-keto esters).



The carbonyl compound can be reduced to an alcohol (Reaction **16-24**) by the *Grignard reagent*, which itself undergoes elimination to give an alkene. The *Grignard reagent* must have a β-carbon that bears a hydrogen atom.

Two other side reactions are condensation (between enolate ion and excess ketone) and *Wurtz-type coupling* (**10-64**). Addition of *Grignard reagents* to ketones cannot be used to prepare highly hindered tertiary alcohols (e.g., triisopropylcarbinol, tri-*tert*-butylcarbinol, and diisopropylneopentylcarbinol) or they can be prepared only in extremely low yields, because reduction and/or enolization become prominent.[506] However, these alcohols can

be prepared by the use of alkyllithium reagents at –80 °C[507] because enolization and reduction are much less important.[508] Other methods of increasing the degree of addition at the expense of reduction include complexing the *Grignard reagent* with $LiClO_4$ or $Bu_4N^+Br^-$,[509] or using benzene or toluene instead of ether as solvent.[510] Both reduction and enolization can be avoided by adding $CeCl_3$ to the *Grignard reagent*.[511]

There has been controversy regarding the mechanism of addition of *Grignard reagents* to aldehydes and ketones.[512] The reaction is difficult to study because of the variable nature of the species present in the *Grignard* solution (Sec. 5.B.ii) and because the presence of small amounts of impurities in the Mg seems to have a great effect on the kinetics of the reaction, making reproducible experiments difficult.[513] There seem to be two basic mechanisms, depending on the reactants and the reaction conditions. In one of these, the R group is transferred to the carbonyl carbon with its electron pair. A detailed mechanism of this type has been proposed by Ashby *et al.*,[514] based on the discovery that this reaction proceeds by two paths: one first order in MeMgBr and the other first order in Me_2Mg.[515] According to this proposal, both MeMgBr and Me_2Mg add to the carbonyl carbon, though the exact nature of the step by which MeMgBr or Me_2Mg reacts with the substrate is not certain. One possibility is a four-centered cyclic transition state:[516]

The other type of mechanism is a SET process[517] with a ketyl intermediate:[518]

This mechanism, which has been mostly studied with diaryl ketones, is more likely for aromatic and other conjugated aldehydes and ketones than it is for strictly aliphatic ones.

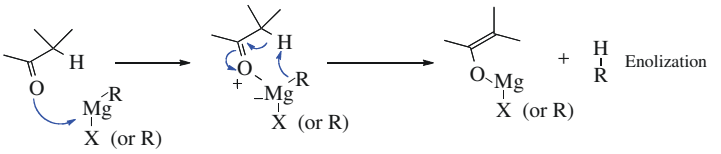
Among the evidence[519] for the SET mechanism are ESR spectra[520] and the fact that $Ar_2C(OH)C(OH)Ar_2$ side products are obtained (from dimerization of the ketyl; see *pinacol coupling* in Reaction **19-76**).[521] In the case of addition of RMgX to benzil (PhCOCOPh), ESR spectra of two different ketyl radicals were observed, both reported to be quite stable at room temperature.[522] Note that a separate study failed to observe freely defusing radicals in the formation of *Grignard reagents*.[523] Carbon isotope effect studies with $Ph^{14}COPh$ showed that the rate-determining step with most *Grignard reagents* is the carbon–carbon bond-forming step (marked *A*), although it is the initial electron-transfer step with allylmagnesium bromide.[524] In the formation of *Grignard reagents* from bromocyclopropane, diffusing cyclopropyl radical intermediates were found.[525] The concerted versus stepwise mechanism has been probed with chiral *Grignard reagents*.[526]



Note that there are similarities in reactivity for the $S_{RN}1$ (see Sec. 13.A.iv) and *Grignard mechanisms*.[527] Experimental evidence from this work suggests a linear rather than a chain mechanism.

Mechanisms for the addition of organolithium reagents have been investigated much less.[528] Addition of a cryptand that binds Li^+ inhibited the normal addition reaction, showing that the lithium is necessary for the reaction to take place.[529]

There is general agreement that the mechanism leading to reduction[530] is usually as follows:

There is evidence that the mechanism leading to enolization is also cyclic, but involves prior coordination with magnesium:[531]

16-25 Addition of Other Organometallics to Aldehydes and Ketones

O **-Hydro-*C*-alkyl-addition**

A variety of organometallic reagents other than RMgX and RLi add to aldehydes and ketones. A simple example is formation of Na, or K alkyne anions (e.g., RC≡C-M, Reaction **16-38**), which undergo acyl addition to ketones or aldehydes to give the propargylic alcohol.[534] In the reaction with terminal acetylenes,[535] sodium acetylides are the most common reagents (when they are used, While Na is the metal of choice for the addition of acetylenic groups, vinylic alanes (prepared as in Reaction **15-17**) are the reagents of choice for the addition of vinylic groups.[536] The reagent $Me_3Al/^{-}C{\equiv}CH\ Na^{+}$ also adds to aldehydes to give the ethynyl alcohol.[537] A solvent-free reaction was reported that mixed a ketone, a terminal alkyne and potassium *tert*-butoxide.[538] The reaction is often called the *Nef reaction*, but Li,[539] Mg, and other metallic acetylides have also been used. A particularly convenient reagent is the lithium acetylide–ethylenediamine complex,[540] a stable, free-flowing powder that is commercially available. Alternatively, the substrate may be treated with the alkyne itself in the presence of a base, so that the acetylide is generated *in situ*. This procedure is called the *Favorskii reaction*, not to be confused with the *Favorskii rearrangement* (**18-7**).[541] Zinc(II) chloride facilitates the addition of a terminal alkyne to an aldehyde to give a propargylic alcohol.[542] Zinc(II) triflate can also be

used for alkyne addition to aldehydes,[543] and in the presence of a chiral ligand leads to good enantioselectivity in the propargyl alcohol product.[544]

The reagents Et_3Al, Et_2Zn, and a terminal alkyne react with ketones, and in the presence of a cinchona alkaloid gives the alkynyl alcohol in moderate ee.[545] Other enantioselective alkynylation reactions are known using various catalysts.[546] Terminal alkynes add to aryl aldehydes in the presence of $InBr_3$ and NEt_3,[547] SmI_2,[548] or Me_2Zn.[549] A Zn mediated reaction using iodoalkynes is known.[550] Catalytically generated zinc acetylides add to aldehydes.[551] An In catalyzed addition of alkynes to aldehydes used a catalytic amount of BINOL and gave the alkynyl alcohol with high enantioselectivity.[552] Other enantioselective addition reactions of terminal alkynes are known.[553] The reaction with In is compatible with the presence of a variety of other functional groups in the molecule, including phosphonate,[554] propargylic sulfides.[555]

Many organometallic reagents have been reported for the addition of allylic groups,[556] and there are enantioselective reactions.[557] One of the most common methods is the *Barbier reaction* noted in Reaction **16-24**, which includes metals and metal compounds other than Mg or Li, although the method is not limited to allylic compounds. Common reagents are allylic In compounds,[558] which add to aldehydes or ketones in various solvents,[559] Enantioselective In mediated *Barbier reactions* are known.[560] Indium reacts with allylic bromides and ketones in water[561] and in aqueous media. The reaction of a

propargyl halide, In, and an aldehyde in aq THF leads to an allenic alcohol.[562] When allyl iodide is mixed with In and TMSCl, reaction with a conjugated ketone proceed by 1,4-addition, but in the presence of 10% CuI, the major product is that of 1,2-addition.[563] Allyl bromide reacts with Mn/TMSCl and an In catalyst in water to give the homoallylic alcohols from aldehydes.[564] Indium metal is used for the acyl addition of allylic halides with a variety of aldehydes and ketones, including aliphatic aldehydes,[565] aryl aldehydes,[566] and α-keto esters.[567] Elimination of the homoallylic alcohol to a conjugated diene can accompany the addition in some cases.[568]

Allyl bromide reacts with a ketone and Sm[569] or SmI_2,[570] to give the homoallylic alcohol. Other metals can be used with allylic halides to give homoallylic alcohols from aldehydes or ketones,[571], including Zn,[572] La,[573] or Mg-Cd[574] and compounds of Ti,[575] Mn,[576] Fe,[577] Ga,[578] Ge,[579] Zr,[580] Nb,[581] Cd,[582] Sb,[583] Te,[584] Ba,[585] Ce,[586] Nd,[587] Hg,[588] Bi,[589] In,[590] and Pb.[591]

In addition, $BiCl_3/NaBH_4$,[592] Mg—$BiCl_3$,[593] and $CrCl_2/NiCl_2$,[594] have been used. Allylic alcohols have been converted to organometallic reagents with diethylzinc and a Pd[595] or a Ru catalyst,[596] leading to the homoallylic alcohol upon reaction with an aldehyde. Allylic acetates add to aldehydes in the presence of a Ru catalyst.[597]

Enantioselective reactions are known.[598] A Cu catalyzed reaction is known that proceeds with good enantioselectivity.[599] Allylzinc bromide adds to aldehydes under solvent-free conditions.[600] A chiral Cr–Mn complex has been used with allylic bromides in conjunction with trimethylsilyl chloride.[601] Reagents of the type R—Yb have been prepared from RMgX.[602] The alkyl group of trialkyl aluminum compounds (e.g., $AlEt_3$) add to aldehydes, enantioselectively in the presence of chiral transition metal complexes.[603] Furthermore, organotitanium reagents can be made to add chemoselectively to aldehydes in the presence of ketones.[604] Organomanganese compounds are also chemoselective in this way.[605] In a related reaction, organocerium reagents, generated from cerium chloride ($CeCl_3$ and a *Grignard reagent* or an organolithium reagent) gives an organometallic reagent that adds chemoselectively.[606] Aryl halides that have a pendant ketone unit react with a Pd catalyst to give cyclization via acyl addition.[607]

As noted in Reaction **16-24**, enolate formation and reduction complicate some *Grignard reactions*. One way to avoid complications is to add $(RO)_3TiCl$, $TiCl_4$,[608] $(RO)_3ZrCl$, or $(R_2N)_3TiX$ to the *Grignard* or organolithium reagent. This produces organotitanium or organozirconium compounds that are much more selective than *Grignard* or organolithium reagents.[609] An important advantage of these reagents is that they do not react with NO_2 or CN functions that may be present in the substrate, as *Grignard* and organolithium reagents do. The reaction of a β-keto amide with $TiCl_4$, for example, gives a complex that allows selective reaction of the ketone unit with MeMgCl—$CeCl_3$ to give the corresponding alcohol.[610] Premixing an allylic *Grignard reagent* with $ScCl_3$ prior to reaction with the

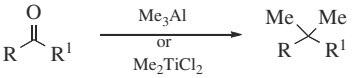
aldehyde gives direct acyl addition without allylic rearrangement as the major product, favoring the *trans*-alkene unit.[611]



Allyltin compounds readily add to aldehydes and ketones.[612] Maleic acid promotes the reaction in aqueous media.[613] Allylic bromides react with Sn to generate the organometallic *in situ*, which then adds to aldehydes.[614] Allylic chlorides react with aldehydes in the presence of ditin compounds (e.g., $Me_3Sn—SnMe_3$ and a Pd catalyst).[615] Allyltrialkyltin compounds[616] and tetraallyltin react with aldehydes or ketones in the presence of BF_3—etherate,[617] or compounds of Cu,[618] Ce,[619] Bi,[620] Pb,[621] Ag[622] Cd,[623] Cr,[624] Pd,[625] Re,[626] Gd,[627] Ti,[628] Rh,[629] Zr,[630] Co,[631] or La.[632] Propargylic tin compounds react with aldehydes to give the alcohol, with good antiselectivity.[633] Tetraallyltin reacts via 1,2-addition to conjugated ketones in refluxing methanol.[634] Tetraallyltin reacts with aldehydes in ionic liquids[635] and on wet silica.[636] In addition, allyltributyltin adds to aldehydes in ionic liquids with $InCl_3$.[637] Tetraallyltin adds to ketones or aldehydes to give homoallylic alcohols with good enantioselectivity in the presence of a chiral Ti complex[638] or a chiral In

complex.[639] Allylic alcohols and homoallylic alcohols add to aldehydes in the presence of $Sn(OTf)_2$[640] In/$InCl_3$,[641] or with a Rh catalyst.[642]

The tin compound can be prepared *in situ* using an α-iodo ketone with an aldehyde and Bu_2SnI_2—LiI.[643] A similar addition occurs with $(allyl)_2SnBr_2$ in water.[644] Asymmetric induction has been reported.[645] The use of a chiral Rh[646] or Ti[647] catalyst leads to enantioselective addition of allyltributyltin to aldehydes. Allyltributyltin reacts with aldehydes in the presence of $SiCl_4$ and a chiral phosphoramide to give the homoallylic alcohol with moderate enantioselectivity.[648] Tetravinyltin adds to ketones in the presence of an In catalyst.[649] Allenyl tin compounds (CH_2=C=$CHSnBu_3$) also react with aldehydes in the presence of BF_3•OEt_2 to give a 2-dienyl alcohol.[650] Selectfluor has been used to induce 1,2-addition of the allyl group of allyltributyltin to a conjugated aldehyde.[651]

Both aluminum and titanium reagents have been used. Aluminum catalysts, (e.g., [methylaluminum bis(4-bromo-2,6-di-*tert*-butylphenoxide)], MABR), facilitate addition of allyltributyltin to aldehydes.[652] Triphenylaluminum reacts with aryl aldehydes in the presence of a Ti catalyst.[653] Trimethylaluminum[654] and dimethyltitanium dichloride[655] exhaustively methylate ketones to give *gem*-dimethyl compounds[656] (see also, Reaction **10-63**):

The Ti reagent also dimethylates aromatic aldehydes.[657] Triethylaluminum reacts with aldehydes, however, to give the mono-ethyl alcohol, and in the presence of a chiral additive the reaction proceeds with good asymmetric induction.[658] A complex of Me_3Ti•MeLi has

been shown to be selective for 1,2-addition with conjugated ketones, in the presence of nonconjugated ketones.[659]

Chiral amides react with aldehydes in the presence of $TiCl_4$ to give syn-selective addition products.[660] Titanium-catalyzed enantioselective additions are also known.[661] High %ee values have been obtained with organometallics,[662] including organotitanium compounds (methyl, aryl, allylic) in which an optically active ligand is coordinated to the Ti,[663] allylic boron compounds, and organozinc compounds. Chiral dendritic Ti catalysts have been used to give moderate enantioselectivity.[664]

Organozinc compounds add to aldehydes and ketones. An example is the reaction of an alkylzinc chloride (RZnCl) to give the corresponding alcohol.[665] Enantioselective reaction of a carbonyl with a dialkylzinc is possible when chiral catalysts are employed,[666] or when chiral ligands[667] are employed.[668] A comparison of the stereoselectivity for reactions of diphenylzinc and diethylzinc has been reported.[669] Dialkylzinc reagents, in the presence of a chiral Ti complex[670] a Zn complex,[671] an Al complex,[672] a chiral Cr complex,[673] a chiral Schiff base,[674] or a chiral bis(sulfonamide[675] and other chiral complexes[676] react with aldehydes or ketones to give

the corresponding alcohol with good enantioselectivity.[677] High enantioselectivity was obtained from R_2Zn reagents (R = alkyl)[678] and aromatic[679] aldehydes by the use of a small amount of various catalysts.[680] The enantioselectivity is influenced by additives (e.g., LiCl).[681] Silica-immobilized chiral ligands[682] can be used in conjunction with dialkylzinc reagents, and polymer-supported ligands have been used.[683]

Propargylic acetate adds to aldehydes with good antiselectivity in the presence of Et_2Zn and a Pd catalyst.[684] With other organometallic compounds, active metals (e.g., alkylzinc reagents)[685] are useful and compounds, such as alkylmercurys, do not react. Dimethylzinc and diethylzinc are probably the most common reagents. An intramolecular version is possible by reaction of an allene–aldehyde with dimethylzinc. Aryl halides react with Zn–Ni complexes to give acyl addition of the aryl group to an aldehyde.[686] The reaction of an allylic halide and Zn[687] or Zn/TMSCl[688] leads to acyl addition of aldehydes.

Organochromium compounds add to aldehydes or ketones.[689] The reaction of an organochromium reagent with an aldehyde or ketone is known as the *Nozaki–Hiyama reaction*. In the original version, a Cr(II) solution was prepared by reduction of chromic chloride by $LiAlH_4$. This product was subsequently treated with an aldehyde and an allylic halide.[690] The coupling of allylic halides and aldehydes or ketones in the presence of a Cr catalyst and a chiral ligand gives products with good enantioselectivity.[691] Enantioselective coupling reactions catalyzed by Cr compounds are of increasing interest.[692] The organochromium reagent may be derived from vinyl halides, triflates, or aryl derivatives.[693]

Other metals facilitate addition of groups to an aldehyde, including the coupling of an alkene to an aldehyde using a Ni catalyst.[694] Vinyl bromides react with $NiBr_2/CrCl_3$/TMSCl to give a reagent that adds to aldehydes to give the allylic alcohol.[695] Vinyl complexes generated from alkynes and SmI_2 add intramolecularly, and eight-membered rings have been formed in this way.[696] Vinyl reagents are formed *in situ* via organozirconium compounds with Me_2Zn, Ti compounds, and terminal alkynes.[697]

Lithium dimethylcopper (Me_2CuLi) reacts with aldehydes[698] and with certain ketones[699] to give the expected alcohols. The RCu(CN)ZnI reagents also react with aldehydes, in the presence of BF_3–etherate, to give secondary alcohols. Vinyltellurium compounds react with $BF_3{\cdot}OEt_2$ and cyanocuprates [R(2-thienyl)$CuCNLi_2$] to give a reagent that adds 1,2- to the carbonyl of a conjugated ketone.[700] Vinyl tellurium compounds also react with *n*-butyllithium to give a reagent that adds to nonconjugated ketones.[701] In conjunction with $BeCl_2$, organolithium reagents add to conjugated ketones. In THF, 1,4- addition is observed, but in diethyl ether the 1,2-addition product is formed.[702]

Alkenes and alkynes add to aldehydes or ketones via the π bond by conversion to a reactive organometallic. A radical-type addition is possible using alkenes with BEt_3. Alkynes add to aldehydes elsewhere in the same molecule in the presence of BEt_3 and a Ni catalyst to give a cyclic allylic alcohol.[703] Alkene aldehydes react similarly using Me_3SiOTf.[704] In a similar manner, dienes[705] or alkynes[706] add to aldehydes in the presence of a Ni catalyst. Allenes add to aldehydes in the presence of a Ni catalyst, using a chiral imidazolinyl carbene ligand, and the product is trapped as the triethylsilyl ether by addition of Et_3SiI.[707] Ketenimines add to aldehydes, in the presence of $SiCl_4$ and an achiral ligand, to give the β-cyanohydrin with good enantioselectivity.[708] Allylic acetates react with ketones to give the homoallylic alcohol under electrochemical conditions that include bipyridyl, tetrabutylammonium tetrafluoroborate, and $FeBr_2$.[709] Terminal alkynes react with Zr complexes and Me_2Zn to give an allylic tertiary alcohol.[710] Internal alkynes also give allylic alcohols in the presence of BEt_3 and a Ni catalyst.[711] Reaction of an aldehyde containing a conjugated diene unit with diethylzinc and a Ni catalyst leads to cyclic

alcohols having a pendant allylic unit.[712] A similar reaction was reported using a Cu catalyst.[713] The intramolecular addition of an alkene to an aldehyde leads to a saturated cyclic alcohol using $PhSiH_3$ and a Co catalyst.[714]

Aryl halides react with a Ni complex under electrolytic conditions to add the aryl group to aldehydes.[715] The C position of an indole adds to aldehydes in the presence of a Pd catalyst.[716] The addition of trifluoromethyl to an aldehyde was accomplished photochemically using CF_3I and $(Me_2N)_2C{=}C(NMe_2)_2$.[717] α-Iodo phosphonate esters react with aldehydes and SmI_2 to give a β-hydroxy phosphonate ester.[718] Addition to the allene in the presence of a Ni catalyst[719] or a $CeCl_3$ catalyst[720] is followed by addition of the intermediate organometallic to the aldehyde to give the cyclic product.

Intramolecular addition of a conjugated ester (via the β-carbon) to an aldehyde generates a cyclic ketone.[721] This type of coupling has been called the *Stetter reaction*,[722] which actually involves the addition of aldehydes to activated double bonds (Reaction **15-34**), mediated by a catalytic amount of thiazolium salt in the presence of a weak base. The intramolecular addition of the allene moiety to an aldehyde is catalyzed by a Pd complex in the presence of $Me_3SiSnBu_3$.[723] A highly enantio- and diastereoselective intramolecular *Stetter reaction* has been developed.[724] Alkynyl aldehydes react with silanes (e.g., Et_3SiH) and a nickel catalyst to give a cyclic compound having a silyl ether and an exocyclic vinylidene unit.[725] Alkene-aldehydes give cyclic alcohols via intramolecular addition of the C=C unit to the carbonyl under electrolytic conditions using a phase-transfer catalyst.[726] A similar cyclization was reported using $SnCl_4$.[727] Vinylidene cycloalkanes react with aldehydes in the presence of a Pd catalyst to give a homoallylic alcohol where addition occurs at the carbon exocyclic to the ring.[728] Allenes react with benzaldehyde using $HCl{-}SnCl_2$ with a Pd catalyst.[729] Silyl allenes react with aldehydes in the presence of a chiral Sc catalyst to give homopropargylic alcohols with good enantioselectivity.[730] Intramolecular addition of an allene to aldehyde via addition of phenyl when treated with PhI and a Pd catalyst.[731] Allenes add to ketones to give homoallylic alcohols in the

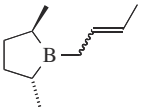
presence of SmI_2 and HMPA.[732] Alkenes having an allylic methyl group in the presence of BF_3•OEt_2 add to formaldehyde to give a homoallylic alcohol.[733] Conjugated dienes react with aldehyde via acyl addition of a terminal carbon of the diene, in the presence of Ni $(acac)_2$ and Et_2Zn.[734]



Although organoboranes do not generally add to aldehydes and ketones,[735] allylic boranes are exceptions.[736] When they add, an allylic rearrangement always takes place. Allylic rearrangements may take place with the other reagents as well. The use of a chiral catalyst leads to asymmetric induction[737] and chiral allylic boranes have been prepared.[738] Addition of trialkylboranes to aldehydes is catalyzed by a Ni complex.[739] Note that chloroboranes (R_2BCl) react with aldehydes via acyl addition of the alkyl group, giving the corresponding alcohol after treatment with water.[740] Treatment with catecholborane gives addition to the conjugated ketone, and subsequent cyclization of the resulting organometallic at the nonconjugated ketone gives a cyclic alcohol with a pendant ketone unit, after treatment with methanol.[741] In the presence of Ru[742] Cu,[743] Ni,[744] or Pd[745] compounds, $RB(OH)_2$ and arylboronic acids [$ArB(OH)_2$, see Reaction **12-28**] add to aldehydes to give the corresponding alcohol. Arylboronic acids add to aldehydes in the presence of a chiral ligand to give an alcohol with good enantioselectivity.[746] An enantioselective intramolecular reaction of an arylboronic acid to a pendant ketone moiety used a Pd catalyst.[747] Polymer-bound aryl borates add an aryl group to aldehydes in the presence of a Rh catalyst.[748] An intramolecular version of the phenylboronic acid induced reaction is known, where a molecule with ketone and conjugated ketone units is converted to a cyclic alcohol using a chiral Rh catalyst.[749] Allylic boronates add to aldehydes,[750] and

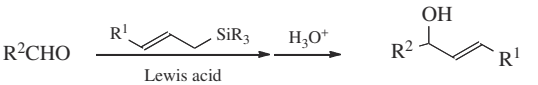
there are enantioselective reactions.[751]

32

33



34

A number of optically active allylic boron compounds have been used, including[752] B-allylbis(2-isocaranyl)borane (**32**),[753] (*E*)- and (*Z*)-crotyl-(*R*,*R*)-2,5-dimethylborolanes (**33**),[754] and the borneol derivative **34**,[755] all of which add an allyl group to aldehydes, with good enantioselectivity. A recyclable 10-TMS-9-borabicyclo[3.3.2]decane has been used for asymmetric allyl and crotyl addition to aldehydes.[756] Where the substrate possesses an aryl group or a triple bond, using a metal carbonyl complex of the substrate enhances enantioselectivity.[757]

Potassium alkynyltrifluoroborates (Reaction **12-28**) react with aldehydes and a secondary amine, in an ionic liquid, to give a propargylic amine.[758] Allylic trifluoroborates (Reaction **12-28**) react with aldehydes to give the homoallylic alcohol. The Pd catalyzed reaction of aryl aldehydes with $PhBF_3K$ gave a diaryl alcohol.[759] A Ru catalyzed reaction of aryltrifluoroborates led to sterically hindered diaryl ketones.[760] Aliphatic aldehydes react with this reagent, in the presence of $BF_3{\cdot}OEt_2$, to give the homoallylic alcohol with allylic rearrangement and a preference for the syn diastereomer.[761] Aryl aldehydes react as well.[762]

16-26 Addition of Trialkylallylsilanes to Aldehydes and Ketones

***O*-Hydro-*C*-alkyl-addition**

Allylic trialkyl, trialkoxy, and trihalosilanes add to aldehydes to give the homoallylic alcohols in the presence of a Lewis acid[763] (including $TaCl_5$[764] and $YbCl_3$[765]), fluoride

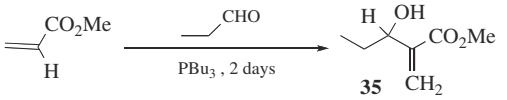
ion,[766] proazaphosphatranes,[767] or a catalytic amount of iodine.[768] A Ru catalyst has been used in conjunction with an arylsilane and an aldehyde.[769] Allyl(trimethoxy)silane adds an allyl group to aldehydes using a CdF_2[770] catalyst or a chiral AgF complex.[771] Allyltrichlorosilanes have also been used in addition reactions with aldehydes.[772] Hünig's base (iPr$_2$NEt) and a sulfoxide have also been used to facilitate the addition of an allyl group to an aldehyde from allyltrichlorosilane.[773] The mechanism of this reaction has been examined.[774]



Allyltrichlorosilane reacts with aldehydes in the presence of certain additives to give the corresponding alcohol,[775] and the reaction proceeds with good enantioselectivity by addition of a chiral additive.[776] Other chiral additives have been used,[777] as well as chiral catalysts,[778] and chiral complexes of allyl silanes.[779] Trimethoxyallylsilanes react with aldehydes in the presence of a Cu catalyst and a chiral ligand to give the chiral alcohol.[780] Chiral allylic silyl derivatives add to aldehydes to give the chiral homoallylic alcohol.[781]

Allylic silanes react with *gem*-diacetates in the presence of $InCl_3$ to give a homoallylic acetate[782] or with dimethyl acetals and TMSOTf in an ionic liquid to give the homoallylic methyl ether.[783] Allylic alcohols can be treated with TMS—Cl and NaI, and then Bi to give an organometallic reagent that adds to aldehydes.[784]

16-27 Addition of Conjugated Alkenes to Aldehydes (the Baylis–Hillman Reaction)[785]

O-Hydro-*C*-alkenyl-addition

35

In the presence of a base[786] (1,4-diazabicyclo[2.2.2]octane, DABCO) or trialkylphosphines, conjugated carbonyl compounds (ketones, esters, including lactones)[787] thioesters,[788] and amides[789]) add to aldehydes via the α carbon to give α-alkenyl-β-hydroxy esters or amides. This sequence is called the *Baylis–Hillman reaction (or Morita–Baylis–Hillman)*,[790] and a simple example is the formation of **35**.[791] Mechanistic investigations of the reaction have been reported.[792] Methyl vinyl ketone gave other products in the *Baylis–Hillman reaction*, whereas conjugated esters do not.[793] Methods that are catalytic in base have been developed for the *Baylis–Hillman reaction*.[794] Both microwave irradiation[795] and ultrasound[796] have been used to induce the reaction.[797] *Baylis–Hillman reactions* have been done in aqueous acidic media.[798] There is a protein-catalyzed reaction.[799] Under certain conditions, rate enhancements have been observed.[800] The reaction has been done in ionic liquids[801] and PEG[802] or sulfolane,[803] and without an organic solvent.[804] Rate

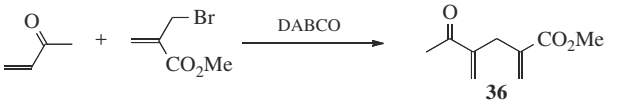
acceleration occurs with bis(arylthio)ureas in a DABCO promoted reaction.[805] Transition metal compounds can facilitate the *Baylis–Hillman reaction*,[806] and BF_3•OEt_2 has been used.[807] A sila variation is known, involving the reaction of vinylsilanes and aldehydes.[808] An *aza-Balyis–Hillman reaction* is discussed in Reaction **16-31**.



An intramolecular version of the *Baylis–Hillman reaction* generated cyclopentenone derivatives from alkyne-aldehydes and a Rh catalyst.[809] Other intramolecular cyclization reactions are known.[810] Cyclization of a conjugated ester using DABCO, where the "alcohol" group contained an aldehyde unit (an α-hydroxy aldehyde derivative) gave a lactone with a hydroxy unit at C-3 relative to the carbonyl and an α-vinylidene.[811]

Enantioselective *Baylis–Hillman reactions*[812] are possible using a chiral auxiliary via an amide[813] or ester.[814] Organocatalysts can be used to give products with good enantioselectivity.[815] Sugars have been used as ester auxiliaries, and in reaction with aryl aldehydes and 20% DABCO gave the allylic alcohol with modest enantioselectivity.[816]

Another variation is the *Rauhut–Currier cyclization* reaction,[817] which involves the reaction of a conjugated carbonyl with the allylic site of a second conjugated system. Intramolecular variations of this latter method are known.[818] With the boron trifluoride induced reaction between an aldehyde and a conjugated ketone, a saturated β-hydroxy ketone was formed with good antiselectivity.[819] The coupling of aldehydes with conjugated ketones used $TiCl_4$,[820] dialkylaluminum halides,[821] and with (polymethyl)hydrosiloxane and a Cu catalyst.[822] Conjugated esters were coupled to aldehydes with DABCO and a La catalyst.[823] Aldehydes are coupled to conjugated esters with a chiral quinuclidine catalyst and a Ti catalyst, as well as in the presence of tosylamine, the final product was the allylic *N*-tosylamine formed with modest enantioselectivity.[824]

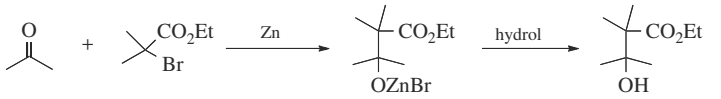
Alkyl halides are coupled with conjugated carbonyls to give the alkylated derivative in what is known as *Morita–Baylis–Hillman alkylation.*[825] α-Bromomethyl esters react with conjugated ketones and DABCO to give a coupling product, (**34**).[826] A similar DBU induced reaction was reported using α-bromomethyl esters and conjugated nitro compounds.[827]



36

The reaction can be modified to give additional products, as with the reaction of *o*-hydroxybenzaldehyde and methyl vinyl ketone with DABCO, where the initial *Baylis–Hillman product* cyclized via conjugate addition of the phenolic oxygen to the conjugated ketone (Reaction **15-31**).[828] Aldehydes and conjugated esters can be coupled with a sulfonamide to give an allylic amine.[829]

See OS ***2010***, 87, 201

16-28 The Reformatsky Reaction

***O*-Hydro-*C*-α-ethoxycarbonylalkyl-addition**

The *Reformatsky reaction*[830] is very similar to Reaction **16-24**. An aldehyde or ketone is treated with Zn and a halide; the halide is usually an α-halo ester or a vinylog (see Sec. 6. B) of an α-halo ester (e.g., RCHBrCH=CHCOOEt), although α-halo nitriles,[831] α-halo ketones,[832] and α-halo *N,N*-disubstituted amides have also been used. Especially high reactivity can be achieved with activated Zn,[833] and with Zn and ultrasound.[834] The reaction is catalytic in Zn in the presence of iodine and ultrasound.[835] Metals other than Zn can be used, including In,[836] Mn,[837] low valent Ti,[838] metal compounds of Ti,[839] Sn,[840]

Sm[841] or Sc.[842] The use of additives (e.g., Ge[843] or Me_2Zn)[844] can lead to highly selective reactions.[845] A combination of Zn and an α-bromo ester can be used in conjunction with BF_3•OEt_2, followed by reaction with dibenzoyl peroxide.[846] The aldehyde or ketone can be aliphatic, aromatic, or heterocyclic, or contain various functional groups. Solvents used are generally ethers, including Et_2O, THF, and 1,4-dioxane, although the reaction can be done in water[847] using dibenzoyl peroxide and $MgClO_4$.

With the use of chiral auxiliaries[848] or chiral catalysts,[849] good enantioselectivity[850] can be achieved.

Dialkylzinc compounds are an alternative source of Zn in the *Reformatsky reaction*. The reaction of an α-bromo ester, an aldehyde, and diethylzinc in THF with a Rh catalyst, gave a β-hydroxy ester.[851]

Formally, the reaction is somewhat analogous to the *Grignard reaction* (**16-24**), with $EtO_2C—C—ZnBr$ (**37**) as an intermediate analogous to RMgX.[852] There *is* an intermediate derived from Zn and the ester, the structure of which has been shown to be **38**, by X-ray crystallography of the solid intermediate prepared from *t*-$BuOCOCH_2Br$ and Zn.[853] As can be seen, it has some of the characteristics of **37**.

38 R = *t*-Bu

After hydrolysis, the alcohol is the usual product, but sometimes (especially with aryl aldehydes) elimination follows directly and the product is an alkene. By the use of Bu_3P along with Zn, the alkene can be made the main product,[854] making this an alternative to the *Wittig reaction* (**16-44**). The alkene is also the product when K_2CO_3/$NaHCO_3$ is used

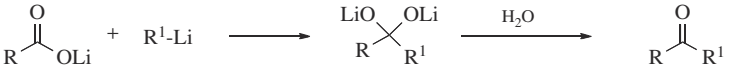
with 2% PEG–telluride.[855] Since *Grignard reagents* cannot be formed from α-halo esters, the method is quite useful, but competing reactions sometimes lead to low yields. A similar reaction (called the *Blaise reaction*) has been carried out on nitriles[856]:

Carboxylic esters have also been used as substrates, but then, as might be expected (Sec. 16.A), the result is substitution and not addition:



The product in this case is the same as with the corresponding nitrile, though the pathways are different. The reaction is compatible with amine substituents, and α-(*N,N*-dibenzyl) amino aldehydes have been used to prepare β-hydroxy-γ-(*N,N*-dibenzylamino) esters with good antiselectivity.[857]

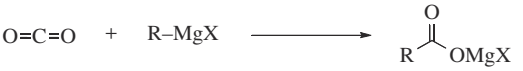
For an alternative approach involving ester enolates, see Reaction **16-36**.

OS **3**, 408; **4**, 120, 444; **6**, 598; **IX**, 275.

16-29 The Conversion of Carboxylic Acid Salts to Ketones with Organometallic Compounds

Alkyl-de-oxido-substitution

Good yields of ketones can often be obtained by treatment of the lithium salt of a carboxylic acid with an alkyllithium reagent, followed by hydrolysis.[858] The carboxylate salt is formed by reaction of the carboxylic acid with 1 molar equivalent of R^1Li. The R′ group may be aryl or primary, secondary, or tertiary alkyl and R may be alkyl or aryl. The compounds MeLi and PhLi have been employed most often. Tertiary alcohols are side products. Lithium acetate can be used, but generally gives low yields. Using R(PrNH)Mg, carboxylic acid salts react to form ketones.[859]



A variation of this transformation reacts the acid with lithium naphthalenide in the presence of 1-chlorobutane. The product is the ketone.[860] A related reaction treats the lithium carboxylate with lithium metal and the alkyl halide, with sonication, to give the ketone.[861] Phenylboronic acid (Reaction **12-28**) reacts with aryl carboxylic acids in the presence of a Pd catalyst and disuccinoyl carbonate to give a diaryl ketone.[862]

16-30 The Addition of Organometallic Compounds to CO_2 and CS_2

C-Alkyl-*O*-halomagnesio-addition

Grignard reagents add to one C=O bond of CO_2 exactly as they do to an aldehyde or a ketone,[863] but the product is the salt of a carboxylic acid. The reaction is usually performed by adding the *Grignard reagent* to dry ice. Many carboxylic acids have been prepared in this manner, and this constitutes an important way of increasing a carbon chain by one unit. Since labeled CO_2 is commercially available, this is a good method for the preparation of carboxylic acids labeled in the carboxyl group. Other organometallic compounds have also been used (RLi,[864] RNa, RCaX, RBa,[865] etc.), but much less often. The formation of the salt of a carboxylic acid after the addition of CO_2 to a reaction mixture is regarded as a positive test for the presence of a carbanion or of a reactive organometallic intermediate in that reaction mixture (see also, Reaction **16-42**).

Aryl organoboronates react with CO_2, in the presence of a Ru catalyst, to give the corresponding aryl carboxylic acid.[866] Aryl and alkenyl boronic esters are carboxylated in the presence of a Cu catalyst.[867] Vinyl halides react with CO and water, with a Pd catalyst in an ionic liquid, to give the conjugated carboxylic acid.[868] Organozinc compounds are carboxylated with CO_2 and a Ni catalyst.[869] Metal-free carboxylation of organozinc reagents is also known.[870] In the presence of CO_2 and an organocatalyst, aromatic aldehydes are converted to the corresponding carboxylic acid.[871] Direct carboxylation of aryl bromides is possible using CO_2 and a Pd catalyst.[872] Allenes are converted to β,γ-unsaturated acids with CO_2 in the presence of Et_2Zn.[873]

When chiral additives (e.g., (−)-sparteine) have added to the initial reaction with the organolithium reagent, quenching with CO_2 produces carboxylic acids with good asymmetric induction.[874]

In a closely related reaction, *Grignard reagents* add to CS_2 to give salts of dithiocarboxylic acids.[875] These salts can be trapped with amines to form thioamides.[876] Two other reactions are worthy of note. (1) Lithium dialkylcopper reagents react with

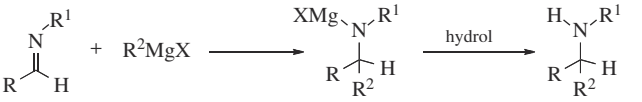
dithiocarboxylic esters to give tertiary thiols.[877] (2) Thiono lactones can be converted to cyclic ethers,[878] for example:



This is a valuable procedure because medium and large ring ethers are not easily made, while the corresponding thiono lactones can be prepared from the readily available lactones (see, e.g., Reaction **16-63**) by reaction **16-11**.

A terminal alkyne can be converted to the anion under electrolytic conditions, in the presence of CO_2, to give propargylic acids ($R—C{\equiv}C—CO_2H$).[879]

16-31 The Addition of Organometallic Compounds to C=N Compounds

***N*-Hydro-*C*-alkyl-addition**

Aldimines can be converted to secondary amines by treatment with *Grignard reagents*.[880] Ketimines generally react with *Grignard reagents* to give reduction instead of addition. However, organolithium compounds give the normal addition product with both aldimines and ketimines.[881] The solvent and the aggregation state of the organolithium play a role in the addition, however.[882] For the addition of an organometallic compound to an imine to give a primary amine, R′ in RCH=NR′ would have to be H, and such compounds are seldom stable. However, the conversion has been done for R = aryl, by the use of the masked reagents $(ArCH{=}N)_2SO_2$ [prepared from an aldehyde, RCHO, and sulfamide, $(NH_2)_2SO_2$]. Addition of R^2MgX or R^2Li to these compounds gives $ArCHR^2NH_2$ after hydrolysis.[883] An intramolecular version of the addition of organolithium reagents is known that gave 2-phenylpyrrolidine.[884] *Grignard reagents* add to imines in the presence of various transition metal catalysts, including $Sc(OTf)_3$[885] or Cp_2ZrCl_2.[886] Alkynes add to imines yielding propargylic amines.[887]

When chiral additives are used in conjunction with the organolithium reagent, chiral amines are produced[888] with good asymmetric induction.[889] Chiral auxiliaries have been used in addition reactions of organometallic compounds to imines,[890] and to oxime derivatives.[891] Transition metal asymmetric alkylation of imines uses metal compounds of Cu.[892] Chiral catalysts lead to enantioselective addition of alkynes to imines to give the amine.[893] Chiral *N*-sulfinylimines reaction with lithium silanes give the α-silylsulfinylamine.[894]

Zinc metal reacts with allylic bromides to form an allylic zinc complex, which reacts with imines to give the homoallylic amine.[895] This reaction is catalyzed by TMSCl.[896] Dialkylzinc reagents add to functionalized imines to give the functionalized amine, often with transition metal catalysts (e.g., Ni compounds).[897] Dialkylzinc reagents add to *N*-tosyl imines to give the alkylated tosylamine.[898] In the presence of a chiral ligand, the metal-catalyzed reaction proceeds with good enantioselectivity.[899] With a Cu catalyst and a chiral ligand the product is formed with good enantioselectivity.[900] The reaction of imines (e.g., $ArN{=}CHCO_2Et$), where R = a chiral benzylic substituent and $ZnBr_2$, followed by R′ZnBr leads to a chiral α-amino ester.[901] Terminal alkynes add to imines using $ZnCl_2$ and TMSCl, and with a chiral ligand attached to nitrogen the reaction proceeds with some enantioselectivity.[902] Dimethylzinc has been used to mediate the addition of terminal alkynes to *N*-tosylimines.[903]

Other organometallic compounds add to aldimines,[904] including Sn,[905] Sm,[906] Ge,[907] Zr,[908] Ga metal with ultrasound,[909] Yb with Me_3SiCl,[910] and In.[911] Catalytic amounts of the metal compound can be used with an allylic stannane.[912] Catalytic enantioselective addition reactions with these organometallics are well known,[913] including reactions in an ionic liquid.[914] Aryltrialkylstannanes add the aryl group to N-tosyl imines using a Rh catalyst and sonication.[915] Allylic halides react with imines in the presence of In metal[916] or $InCl_3$[917] to give the homoallylic amine, and with N-sulfonyl imines to give the homoallylic sulfonamide.[918] In this latter reaction, antiselectivity was observed when the reaction was done in water, and syn selectivity when done in aq THF.[919] Aryl iodides add to *N*-aryl imines in the presence of a Rh catalyst.[920] Arylation of *N*-tosyl ketimines proceeds with good enantioselectivity using a Rh catalyst.[921] Propargylic halides add to imines in the presence of In metal, in aq THF.[922]

Terminal alkynes react with aryl aldehydes and aryl amines to give propargylic amine without a catalyst.[923] Alternatively, with an Ir[924] or a Cu catalyst[925] they also lead to a propargylic amine.[926] Terminal alkynes add to *N*-substituted imines to give a propargylic amine with good enantioselectivity using a chiral Cu complex.[927] Lithium alkyne anions add to chiral *N*-sulfinylimines, in the presence of Me_3Al, to give the chiral propargyl

compound.[928] Diynes add to *N*-sulfinyl imines in the presence of a chiral Rh catalyst to give the corresponding allylic sulfinylamine.[929] Alkenes add to N-sulfonyl imines in the presence of a chiral Rh catalyst to give the alkylated sulfonamide.[930]

Triethylaluminum adds an ethyl group to an imine in the presence of a Eu catalyst. Reaction with $PhSnMe_3$ and *N*-tosylimines with a Rh catalyst leads to addition of a phenyl group to the carbon of the C=N bond.[931] Other *N*-sulfonyl imines react similarly to give the corresponding sulfonamide, and in the presence of a chiral ligand the reaction proceeds to good enantioselectivity.[932] *N*-Tosyl imines also react with dialkylzinc reagents, giving the sulfonamide with modest enantioselectivity.[933] *N*-Sulfinyl imines [$R_2CH{=}NS(=O)R'$][934] react with Grignard reagents at carbon to give the corresponding *N*-sulfinylamine.[935] Furan derivatives add via C-2 with good enantioselectivity using a chiral phosphoric acid catalyst.[936] Alkenes add to *N*-tosyl imines with a Yb catalyst[937] and allenes add to *N*-carbamoyl imines in the presence of a V catalyst.[938] *N*-Carbamoyl imines, formed *in situ*, react with allylic silanes in the presence of an iodine catalyst.[939] *N*-Carbamoyl imines add acetonitrile (via carbon) using DBU and a Ru catalyst.[940]

Arylboronates (Reaction **12-28**) add to *N*-sulfonyl imines in the presence of a Rh catalyst to give the corresponding sulfonamide.[941] Chiral Cu complexes have also been used for effective allylation of ketimines.[942] Aryl boronic acids (Reaction **12-28**) add the aryl group to *N*-tosyl imines using a Rh[943] or Pd[944] catalyst. Arylboronic acids react similarly, and in the presence of a chiral Rh[945] or Ir[946] catalyst give a chiral sulfinamide or sulfonamide. Allylic boronates also add to aldehydes, and subsequent treatment with ammonia gives the homoallylic amine.[947] Vinyl boronates add to nitrones in the presence of Me_2Zn, transferring the vinyl group to the C=N unit.[948] Potassium allyltrifluoroborates react with *N*-tosyllimines in the presence of a Pd catalyst.[949]

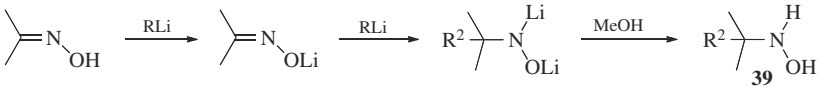
Allylic silanes (e.g., allyltrimethylsilane) add to *N*-substituted imines in the presence of a Pd catalyst to give the homoallylic amine.[950] Similar results are obtained when the allylic silane and imine are treated with a catalytic amount of tetrabutylammonium fluoride.[951] Allylic trichlorosilanes add to hydrazones to give homoallylic hydrazine derivatives with excellent antiselectivity[952] and with good enantioselectivity using a chiral ligand.[953] Chiral allylic silane derivatives have been developed, and add to hydrazones with good enantioselectivity.[954]

There is an *aza-Balyis–Hillman reaction* that converts imines and conjugated carbonyl derivatives to the α-amino conjugated derivative.[955] *N*-Tosyl imines can be used in place of aldehydes, and the reaction of the imine, a conjugated ester and DABCO gave the allylic *N*-tosylimine.[956] A "double *Baylis–Hillman*" *reaction* has also been reported using *N*-tosylimines and conjugated ketones.[957] The use of chiral catalysts leads enantioselective product formation.[958] An enantioselective aza-*Baylis–Hillman reaction*[959] was reported using as chiral reaction medium.[960] Aldehydes add via the α carbon using proline, to give β-amino aldehydes with good selectivity to give chiral β-amino aldehydes.[961]



Silyl enol ethers add to hydrazones in the presence of ZnF_2 and a chiral ligand to give chiral β-hydrazino ketones.[962] Similar addition to imine derivatives was accomplished using ketene silyl acetals and Amberlyst-15.[963] Alternatively, an imine is reacted first with $Zn(OTf)_2$ and then with a ketene silyl acetal.[964]

Nitro compounds add to *N*-carbamoyl imines with a chiral diamine catalyst with some enantioselectivity.[965] Nitro compounds add via carbon using a Cu catalyst, and with good enantioselectivity when a chiral ligand is used.[966] The conjugate bases of nitro compounds (formed by treatment of the nitro compound with BuLi) react with Grignard reagents in the presence of $ClCH{=}NMe_2^+\ Cl^-$ to give oximes: $RCH{=}N(O)OLi + R'MgX \rightarrow RR'C{=}NOH$.[967]

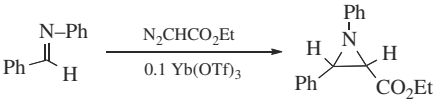
Iminium salts[968] give tertiary amines directly, via 1,2-addition to the C=N unit. Chloroiminium salts [ClCH=NR_2'Cl^-, generated *in situ* from an amide ($HCONR_2$') and phosgene ($COCl_2$)] react with 2 molar equivalents of a *Grignard reagent* RMgX, one adding to the C=N and the other replacing the Cl, to give tertiary amines R_2CHNR_2'.[969]



Many other C=N systems (phenylhydrazones, oxime ethers, etc.) give 1,2-addition when treated with *Grignard reagents*, while some gave reductions and others gave miscellaneous reactions. Organocerium reagents add to hydrazones.[970] Indium metal promotes the addition of alkyl iodides to hydrazones.[971] A hydrazone can be formed *in situ* by reacting an aldehyde with a hydrazine derivative. In the presence of tetrallyltin and a Sc catalysts, homoallylic hydrazine derivatives are formed.[972] Hydrazone derivatives react with iodoalkenes in the presence of $InCl_3$ and $Mn_2(CO)_{10}$ under photochemical conditions to give the hydrazine derivative.[973] Ketene dithioacetals add to hydrazones using a chiral Zr catalyst to give a pyrazolidine.[974] Oximes can be converted to hydroxylamines (**39**) by treatment with 2 molar equivalents of an alkyllithium reagent, followed by methanol.[975] Oxime ethers add an allyl group upon reaction with allyl bromide and In metal in water.[976] Nitrones [$R_2C{=}N^+(R')—O^-$] react with allylic bromides and Sm to give homoallylic oximes,[977] and with terminal alkynes and a Zn catalyst to give propargylic oximes.[978] *Grignard reagents* also add to nitrones.[979] Nitrones react with $CH_2{=}CHCH_2InBr$ in aq DMF to give the homoallylic oxime[980] and silyl ketene acetals add in the presence of a chiral Ti catalyst to good enantioselectivity.[981]

Allylic alcohols add to imines in the presence of a Pd catalyst to give the homoallylic amine.[982]

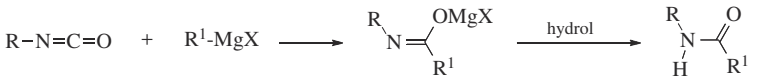
16-32 Addition of Carbenes and Diazoalkanes to C=N Compounds



In the presence of metal catalysts [e.g., $Yb(OTf)_3$], diazoalkanes add to imines to generate aziridines.[983] The reaction is somewhat selective for the cis-diastereomer. The use of chiral additives in this reaction leads to aziridines enantioselectively.[984] Imines can be formed by the reaction of an aldehyde and an amine, and subsequent treatment with Me_3SiI and butyllithium gives an aziridine.[985] *N*-Tosyl imines react with diazoalkenes to form *N*-tosyl aziridines, with good cis selectivity[986] and modest enantioselectivity in the presence of a chiral Cu catalyst,[987] but give excellent enantioselectivity with a chiral Rh catalyst[988] or with the use of an organocatalyst.[989] Note that *N*-tosyl aziridines are formed by the reaction of an alkene with PhI=NTs and a Cu catalyst.[990] *N*-Acylimines react with diazoesters via C—H insertion using a Pt catalyst.[991] The reaction of alkenes with diazo compounds is discussed in Reaction **15-53**.

16-33 The Addition of Grignard Reagents to Nitriles and Isocyanates

Alkyl,oxo-de-nitrilo-tersubstitution (Overall transformation)

***N*-Hydro-*C*-alkyl-addition**

Ketones can be prepared by addition of *Grignard reagents* to nitriles, followed by hydrolysis of the initially formed imine anion. Many ketones have been made in this manner, though when both R groups are alkyl, yields are not high.[992] Yields can be improved by the use of Cu(I) salts[993] or by using benzene containing 1 equiv of ether as the

solvent, rather than ether alone.[994] In general, the ketimine salt does not react with *Grignard reagents*: Hence, tertiary alcohols or tertiary alkyl amines are not often side products.[995] By careful hydrolysis of the salt, it is sometimes possible to isolate ketimines ($RR'C{=}NH$),[996] especially when R and R′ = aryl. The addition of *Grignard reagents* to the C≡N group is normally slower than to the C=O group, and cyano group containing aldehydes add the *Grignard reagent* without disturbing the CN group.[997] Organolithium reagents add to nitriles, mediated by LiBr, to form N-acetyl enamines.[998] Other metal compounds have been used, including Sm with allylic halides[999] and organocerium compounds (e.g., $MeCeCl_2$).[1000] Allylic halides react with an excess of Zn metal in the presence of 40% $AlCl_3$ and in the presence of a nitrile, to give homoallylic ketones after hydrolysis.[1001]

Addition of *Grignard reagents*[1002] or organolithium reagents[1003] to ω-halo nitriles leads to 2-substituted cyclic imines.

The *Blaise reaction* is the reaction of the organozinc reagent derived from a α-bromoester with Zn metal and a nitrile to give the corresponding β-ketoester.[1004]

The following mechanism has been proposed for the reaction of the methyl *Grignard reagent* with benzonitrile[1005]:

Arylboronic acids add to nitriles in the presence of a Pd catalyst.[1006] Aryl and alkenylboronic acids add to isocyanates in the presence of a Pd[1007] or Rh[1008] catalyst.

Arenes add to nitriles in the presence of a Pd catalyst in DMSO/trifluoroacetic acid to give a diaryl ketone.[1009]

The addition of *Grignard reagents* to isocyanates gives, after hydrolysis, *N*-substituted amides.[1010] This is a very good reaction and can be used to prepare derivatives of alkyl and aryl halides. The reaction has also been performed with alkyllithium compounds.[1011]

Isothiocyanates give *N*-substituted thioamides. Other organometallic compounds add to isocyanates. Vinyltin reagents lead to conjugate amides.[1012]

Note that terminal alkynes add to the carbon of an isonitrile in the presence of a uranium complex, giving a propargylic imine.[1013]

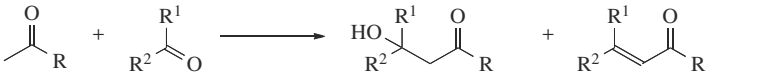
G. Carbon Attack by Active Hydrogen Compounds



Reactions **16-34**–**16-50** are base-catalyzed condensations (although some of them are also catalyzed to acids).[1014] In Reactions **16-34**–**16-44**, a base removes a C—H proton to give a carbanion, which then adds to a C=O. The oxygen acquires a proton, and the resulting alcohol may or may not be dehydrated, depending on whether an α hydrogen is present and on whether the new double bond would be in conjugation with double bonds already present:

The reactions differ in the nature of the active hydrogen component and the carbonyl component. Table 16.2 illustrates the differences. Reaction **16-50** is an analogous reaction involving addition to C≡N.

16-34 The Aldol Condensation[1015]

***O*-Hydro-*C*-(α-acylalkyl)-addition; α-Acylalkylidine-de-oxo-bisubstitution**

(if an α-H was present)

In the *aldol reaction* or *aldol condensation*[1016] the α carbon of one aldehyde or ketone molecule adds to the carbonyl carbon of another.[1017] Although acid-catalyzed aldol reactions are known,[1018] the most common form of the reaction uses a base. There is evidence that an SET mechanism can intervene when the substrate is an aromatic

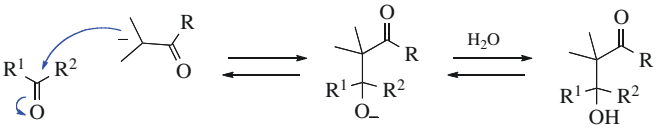
16-50	*Thorpe*		Nitrile	



ketone.[1019] Although hydroxide was commonly used in early versions of this reaction, stronger bases [e.g., alkoxides (RO^-) or amides (R_2N^-)] are also common. Amine bases have been used to catalyze the aldol condensation.[1020] Hydroxide ion is not a strong

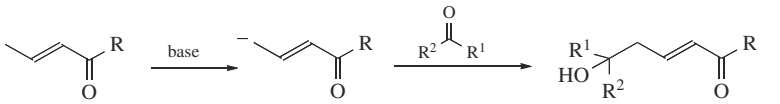
enough base to convert substantially all of an aldehyde or ketone molecule to the corresponding enolate ion; that is, the equilibrium lies well to the left, for both aldehydes

and ketones. Nevertheless, enough enolate ion is present for the reaction to proceed:



This equilibrium lies further to the right with alkoxide relative to hydroxide, but the equilibrium still lies predominantly to the left. With amide bases, and particularly with aprotic solvents, the equilibrium usually lies much more to the right when compared with alkoxides or hydroxide. Protic solvents, (e.g., water or alcohol) are acidic enough to react with the enolate anion and shift the equilibrium to the left. As noted, in an aprotic solvent (e.g., ether or THF), with a strong amide base (e.g., LDA, sec. Sec. 8.F, category 7), the equilibrium lies more to the right.[1021] A variety of amide bases can be used to deprotonate the ketone or aldehyde, and in the case of an unsymmetrical ketone removal of the more acidic proton leads to the kinetic enolate anion.[1022] Note that a polymer-bound amide base has been used[1023] and solid-phase chiral lithium amides are known.[1024] A polymer-supported phosphoramide has been used as a catalyst for the aldol condensation.[1025]

The product of an aldol condensation is a β-hydroxy aldehyde (called an *aldol*) or a β-hydroxy ketone, which in some cases is dehydrated during the course of the reaction. An aldol is readily isolated unless the substrate is an aromatic aldehyde or ketone when the reaction is done in aprotic solvents with a mild workup procedure. The aldol reaction has been done in ionic liquids.[1026] Even if the dehydration is not spontaneous, it can usually be done easily, since the new double bond is in conjugation with the C=O bond; so that this is a method of preparing α,β-unsaturated aldehydes and ketones, as well as β-hydroxy aldehydes and ketones. One-pot procedures have been reported to give the conjugated product.[1027] The entire reaction is an equilibrium (including the dehydration step), and α,β-unsaturated and β-hydroxy aldehydes and ketones can be cleaved by treatment with $^{-}$OH (the *retrograde aldol reaction*). The retro-aldol condensation has been exploited for crossed-aldol reactions.[1028] A vinylogous (Sec. 6.B) aldol reaction is known[1029] as is a

'double' aldol.[1030] Enzyme-mediated aldol reactions have been reported using two aldehydes, including formaldehyde.[1031]

Under the principle of vinylogy (Sec. 6.B), the active hydrogen can be one in the γ position of an α,β-unsaturated carbonyl compound:

The scope of the aldol reaction may be discussed under five headings:

1. *Reaction between Two Molecules of the Same Aldehyde*. Homo-coupling. Hydroxide or alkoxide bases are used in protic solvents,[1032] and the reaction is quite feasible. Nowadays, the use of dialkylamide bases in aprotic solvents (e.g., ether or THF) is more common. Many aldehydes have been converted to aldols and/or their dehydration products in this manner. The most effective catalysts are basic ion-exchange resins. Of course, the aldehyde must possess an α hydrogen.
2. *Reaction between Two Molecules of the Same Ketone*. Homo-coupling. With hydroxide or alkoxide bases in protic solvents the equilibrium lies well to the left,[1033] and the reaction is feasible only if the equilibrium can be shifted. This can often be done by allowing the reaction to proceed in a Soxhlet extractor (e.g., See OS **I**, 199). As with aldehydes, the use of dialkylamide bases (e.g., LDA or lithium hexamethyldisilazide, Sec. 8.F., category 7) in aprotic solvents (e.g., ether or THF) are more common. Unsymmetrical ketones condense on the side that has the most hydrogens with dialkylamide bases in aprotic solvents, but on the side with the fewest hydrogens with alkoxide bases in alcohol solvents.
3. *Reaction between Two Different Aldehydes*. Cross-coupling. In protic solvents with an alkoxide base, this will produce a mixture of four products (eight, if the alkenes are counted). However, if one aldehyde does not have an α hydrogen, only two aldols are possible, and in many cases the crossed product is the main one. The crossed-aldol reaction is often called the *Claisen–Schmidt reaction*.[1034] The crossed-aldol reaction is readily accomplished using amide bases in aprotic solvent. The first aldehyde is treated with LDA in THF at –78 °C, for example, to form the enolate anion. Subsequent treatment with a second aldehyde leads to the mixed-aldol product. The crossed aldol of two aldehydes has been done using potassium *tert*-butoxide and $Ti(OBu)_4$.[1035]
4. *Reaction between Two Different Ketones*. Cross-coupling. This is seldom attempted with hydroxide or alkoxide bases in protic solvents since similar considerations apply to those discussed for aldehydes. This reaction is commonly done with amide bases in aprotic solvents, but with somewhat more difficulty than with aldehydes.

5. *Reaction between an Aldehyde and a Ketone.* This is usually feasible with hydroxide or alkoxides bases in protic solvents when the aldehyde has no α hydrogen, since there is no competition from ketone condensing with itself.[1036] This is also called the *Claisen–Schmidt reaction*. Even when the aldehyde has an α hydrogen, it is generally the α carbon of the ketone that adds to the carbonyl of the aldehyde, not the other way around. Mixtures are usually produced, however. If the ketone or the aldehyde is treated with an amide base in aprotic solvents, a second aldehyde or ketone can be added to give the aldolate with high regioselectivity. The reaction can be also made regioselective by preparing an enol derivative of the ketone separately[1037] and then adding this to the aldehyde (or ketone). Other types of preformed derivatives that react with aldehydes and ketones are enamines (with a Lewis acid catalyst),[1038] and enol borinates ($R'CH{=}CR^2{-}OBR_2$),[1039] which can be synthesized by Reaction **15-27** or directly from an aldehyde or ketone[1040]. Preformed metallic enolates are also used. For example, lithium enolates[1041] (prepared by Reaction **12-23**) react with the substrate in the presence of $ZnCl_2$.[1042] In this case, the aldol product is stabilized by chelation of its two oxygen atoms with the zinc ion.[1043] Other metallic enolates can be used for aldol reactions, either preformed or generated *in situ* with a catalytic amount of a metal compound. Compounds used for this purpose include metal complexes of Mg,[1044] Ti,[1045] Zr,[1046] Pd,[1047] In,[1048] Sn,[1049] La,[1050] and Sm,[1051] all of which give products with moderate-to-excellent diastereoselectivity[1052] and regioselectivity. α-Alkoxy ketones react with lithium enolates particularly fast.[1053] A bis(aldol) condensation has been reported with epoxy ketones and aldehydes using SmI_2.[1054]

There are discussions that relate to the transition state of the aldol condensation. There is experimental evidence for chair-like transition states in the aldol reactions of methyl

ketone lithium enolate anions.[1055] A computational study gave the gas-phase activation energies for lithium enolate anions in an aldol-type reaction.[1056] There is a computational study of the mechanism for an aldol reaction in pure water.[1057]

The reactions with pre-formed enol derivatives provide a way to control the stereoselectivity of the aldol reaction.[1058] As with the *Michael reaction* (**15-24**), the aldol reaction creates two new stereogenic centers. In the most general case, there are four stereoisomers of the aldol product (two racemic diastereomers), which can be represented as the syn and anti diastereomers shown. The reaction may be diastereoselective, however, if one is preferred over the other.

Syn (here erythro) (±) pair Anti (here threo) (±) pair

Among the preformed enol, derivatives used for diastereoselective aldol condensations have been enolates of Li,[1059] Mg, Ti,[1060] and Sn,[1061] silyl enol ethers,[1062] enol borinates,[1063] and enol borates [$R'CH{=}CR^2OB(OR)_2$].[1064] The nucleophilicity of silyl enol ethers has been examined[1065] and reactions of these compounds are discussed in Reaction **16-35**.

Base-induced formation of the enolate anion generally leads to a mixture of (*E*)- and (*Z*)-isomers, and dialkyl amide bases are used in most cases. The (*E*/*Z*) stereoselectivity depends on the structure of the lithium dialkylamide base, with the highest (*E*/*Z*) ratios obtained with LiTMP–butyllithium mixed aggregates in THF.[1066] The use of LiHMDS resulted in a reversal of the (*E*/*Z*) selectivity. In general, metallic (*Z*)-enolates give the syn (or erythro) pair, and this reaction is highly useful for the diastereoselective synthesis of these products.[1067] The (*E*) isomers generally react nonstereoselectively. However, anti-stereoselectivity has been achieved in a number of cases, with Ti enolates,[1068] with Mg

enolates,[1069] with certain enol borinates,[1070] and with lithium enolates at –78 °C.[1071] Enolization accounts for syn–anti isomerization of aldols.[1072] In another variation, a β-keto *Weinreb amide* (see Reaction **16-82**) reacted with $TiCl_4$ and *Hünig's base* ($i Pr_2NEt$) and then an aldehyde to give the β-hydroxy ketone.[1073]

These reactions are enantioselective[1074] (in which case only one of the four isomers predominates)[1075] by using[1076] chiral enol derivatives,[1077] chiral aldehydes or ketones,[1078] or both.[1079] Chiral bases[1080] can be used (e.g., proline),[1081] proline derivatives,[1082] or chiral additives used in conjunction with an organobase.[1083] Indeed, chiral organocatalysts are increasingly important,[1084] including those that can be used in aqueous

media.[1085] Chiral auxiliaries[1086] have been developed that can be used in conjunction with the aldol condensation, as well as chiral transition metal complexes[1087] and chiral ligands[1088] in catalytic reactions. The enantioselective condensation of methyl vinyl ketone and an aldehyde used a chiral Zn catalyst.[1089] Structural variations in the aldehyde or ketone are compatible with many enantioselective condensation reactions. An α-hydroxy ketone was condensed with an aldehyde using a chiral Zn catalyst to give the aldol (an α,β-dihydroxy ketone) with good syn selectivity and good enantioselectivity.[1090] Chiral vinylogous aldol reactions (Sec. 6.B) have been reported.[1091] Formation of the magnesium enolate anion of a chiral amide, adds to aldehydes to give the alcohol enantioselectively.[1092] Diamine protonic acids have been used for catalytic asymmetric aldol reactions.[1093]

Silyl enol ethers react with aldehydes in the presence of chiral boranes[1094] or other additives[1095] to give aldols with good asymmetric induction (see the *Mukaiyama aldol Reaction* in **16-35**). Chiral boron enolates have been used.[1096] Since both new stereogenic centers are formed enantioselectively, this kind of process is called *double asymmetric synthesis*.[1097] Where both the enolate derivative and substrate were achiral, carrying out the reaction in the presence of an optically active boron compound[1098] or a diamine coordinated with a Sn compound[1099] gave the aldol product with excellent enantioselectivity for one stereoisomer. Boron triflate (R_2BOTf) derivatives have been used for the condensation of ketals and ketone to give β-alkoxy ketones.[1100]

It is possible to make the α carbon of the aldehyde add to the carbonyl carbon of the ketone, by using an imine instead of an aldehyde, and $LiN(iPr)_2$ as the base to form the α-lithio imine (**40**).[1101] This is known as a *directed aldol reaction*. Similar reactions have been performed with α-lithiated dimethylhydrazones of aldehydes or ketones[1102] and with α-lithiated aldoximes.[1103]

The aldol reaction can also be performed with acid catalysts, as mentioned above, in which case dehydration usually follows. Here there is initial protonation of the carbonyl group, which attacks the α carbon of the *enol* form of the other molecule[1104]:

With respect to the enol, this mechanism is similar to that of halogenation (Reaction **12-4**). A side reaction that is sometimes troublesome is further condensation, since the product of an aldol reaction is still an aldehyde or ketone. The aldol condensation of aldehydes has also been done using a mixture of pyrrolidine and benzoic acid.[1105]

The intramolecular aldol condensation is well known, and aldol reactions are often used to close five- and six-membered rings. Because of the favorable entropy (Sec. 6.D), such ring closures generally take place with ease[1106] when using hydroxide or alkoxide bases in protic solvents. In aprotic solvents with amide bases, formation of the enolate anion occurs by deprotonation of the more acidic site, followed by cyclization to the second carbonyl. The acid-catalyzed intramolecular aldol condensation is known, and the mechanism has been studied.[1107] Stereoselective proline-catalyzed intramolecular aldol reactions give the cyclized product with good enantioselectivity.[1108] Chiral ligands, in conjugation with transition metal compounds of Cu[1109], lead to asymmetric intramolecular aldol condensation reactions. An asymmetric intramolecular aldol reaction was catalyzed by a chiral

amine.[1110] The regioselectivity of an intramolecular aldol condensation of unsaturated 1,5-diketones is strongly influenced by the presence or absence of a trialkylphosphine.[1111]

An important extension of the intramolecular aldol condensation is the *Robinson annulation* reaction,[1112] which has often been used in the synthesis of steroids and terpenes. In original versions of this reaction, a cyclic ketone is converted to another cyclic ketone under equilibrium conditions using hydroxide or alkoxide bases in a protic solvent, forming one additional six-membered ring containing a double bond. The reaction can be done in a stepwise manner using amide bases in aprotic solvents. In the reaction with hydroxide or alkoxide bases in alcohol or water solvents, the substrate is treated with methyl vinyl ketone (or a simple derivative of methyl vinyl ketone) and a base.[1113] The enolate ion of the substrate adds to the methyl vinyl ketone in a *Michael reaction* (**15-24**) to give a diketone that undergoes or is made to undergo an internal aldol reaction and subsequent dehydration to give the product.[1114] The *Robinson annulation* can be combined with alkylation.[1115] Enantioselective *Robinson annulation* techniques have been developed, including a proline-catalyzed reaction.[1116] The *Robinson annulation* has been done in ionic liquids[1117] and a solvent-free version of the reaction is known.[1118]

Because methyl vinyl ketone has a tendency to polymerize, surrogates are often used instead (i.e., compounds that will give methyl vinyl ketone when treated with a base). One common example, $MeCOCH_2CH_2NEt_2Me^+\ I^-$ (see Reaction **17-9**), is easily prepared by quaternization of $MeCOCH_2CH_2NEt_2$, which itself is prepared by a *Mannich Reaction* (**16-19**) involving acetone, formaldehyde, and diethylamine. α-Silylated vinyl ketones [$RCOC(SiMe_3)=CH_2$] have also been used successfully in annulation reactions[1119] because the $SiMe_3$ group is easily removed. When the ring closure of a 1,5-diketone is catalyzed by the amino acid (*S*)-proline, the product is optically active with high ee.[1120] *Stryker's reagent,*[1121] $[(Ph_3P)CuH]_6$, has been used for an intramolecular addition where a ketone enolate anion adds to a conjugated ketone, giving cyclic alcohol with a pendant ketone unit.[1122]

16-35 Mukaiyama Aldol and Related Reactions[1123]

O-Hydro-*C*-(α-acylalkyl)-addition

An important variation of the aldol condensation involves treatment of an aldehyde or ketone with a silyl ketene acetal [$R_2C{=}C(OSiMe_3)OR'$][1124] or a silyl enol ether, in the presence of $TiCl_4$[1125], to give **41**. This variation is known as the *Mukaiyama aldol reaction*, or simply the *Mukaiyama reaction*. The silyl ketene acetal can be considered a pre-formed enolate that gives aldol product with $TiCl_4$ in aqueous solution, or with no

41

catalyst at all.[1126] A combination of $TiCl_4$ and *N*-tosyl imine has also been used to facilitate the Mukaiyama aldol reaction.[1127] Reaction at the carbonyl of saturated carbonyl compounds is significantly faster than 1,2-addition to unsaturated carbonyl compounds.[1128] The mechanism of this reaction has been explored.[1129] Other catalysts have been used for this reaction, including $InCl_3$,[1130] SmI_2,[1131] HgI_2,[1132] $Yb(OTf)_3$,[1133] $Cu(OTf)_2$,[1134] $LiClO_4$,[1135] $VOCl_3$,[1136] an Fe catalyst,[1137] and $Bi(OTf)_3$.[1138] Lithium perchlorate in acetonitrile (5 M) can be used for the reaction of an aldehyde and a silyl enol ether.[1139]

The reaction can be done in water using a Sc catalyst[1140] or on a Montmorillonite K-10 clay.[1141] Silyl enol ethers react with aq formaldehyde in the presence of TBAF to give the aldol product.[1142] A catalytic amount of Me_3SiCl facilitates the Ti mediated reaction.[1143] Sulfonamides (e.g., $HNTf_2$) have been used as a catalyst[1144] as has pyridine *N*-oxide[1145] and *N*-methylimidazole.[1146] An *ab initio* study of the uncatalyzed Mukaiyama aldol reaction showed that the nucleophilicity of silyl enol ether and the electrophilicity of the aldehyde are important in promoting the reactivity.[1147] This reaction can also be run with the aldehyde or ketone in the form of its acetal [$R^3R^4C(OR')_2$], in which case the product is the ether $R^1COCHR_2CR^3R^4OR'$ instead of **41**.[1148] Vinylogous (Sec. 6.B) silyl ketene acetals with Ti,[1149] Cu,[1150] In,[1151] Fe,[1152] or Zn[1153] catalysts or an organocatalyst,[1154] give the product with good enantioselectivity.

Silyl enol ethers[1155] derived from esters (silyl ketene acetals) react with aldehydes in the presence of various catalysts to give β-hydroxy esters. Water accelerates the reaction of an aldehyde and a ketene silyl acetal with no other additives.[1156] The reaction is catalyzed by triphenylphosphine[1157] and also by $SiCl_4$ with a chiral bis(phosphoramide) catalyst.[1158] The reaction was done without a catalyst in an ionic liquid.[1159] A vinylogous reaction (Sec. 6.B) is known that gives δ-hydroxy-α,β-unsaturated esters.[1160] An interesting variation in this reaction combined an intermolecular *Mukaiyama aldol* followed by an intramolecular reaction (a "domino" *Mukaiyama aldol*) that gave cyclic conjugated ketone products.[1161] Under different conditions, silyl ketene acetals of conjugated esters react with aldehydes to give conjugated lactones.[1162] Imines react with silyl ketene acetals in the presence of SmI_3

to give β-amino esters.[1163] Imines react with silyl enol ethers in the presence of BF_3•OEt_2 to give β-amino ketones.[1164] Silyl ketene acetals also undergo conjugate addition in reactions with conjugated ketones.[1165] Propargylic acetals react with silyl enol ethers and a Sc catalyst to give β-alkoxy ketones.[1166] α-Silyl silyl enol ethers [RCH=CH(OTMS)$SiMe_3$] react with acetals in the presence of $SnCl_4$ to give β-alkoxy silyl ketones.[1167] Borane derivatives [e.g., C=C—$OB(NMe_2)_2$] react with aldehydes to give β-amino ketones.[1168]

Asymmetric *Mukaiyama aldol reactions* and reactions of silyl ketene acetals have been reported,[1169] usually using chiral additives[1170] although chiral auxiliaries have also been used.[1171] Chiral catalysts, usually transition metal complexes using chiral ligands, are quite effective[1172] but chiral organocatalysts[1173] are increasingly important.

Enol acetates and enol ethers also give this product when treated with acetals and $TiCl_4$ or a similar catalyst.[1174] A variation of this condensation uses an enol acetate with an aldehyde in the presence of Et_2AlOEt to give the aldol product.[1175]

16-36 Aldol-Type Reactions between Carboxylic Acid Derivatives and Aldehydes or Ketones

O-Hydro-*C*-(α-alkoxycarbonylalkyl)-addition; α-Alkoxycarbonylalkylidene-de-oxo-bisubstitution

In the presence of a strong base, removal of a proton from the α carbon of a carboxylic ester or other acid derivative generates an enolate anion that can condense with the carbonyl carbon of an aldehyde or ketone to give a β-hydroxy ester,[1176] amide, and so on. These products may or may not be dehydrated to the α,β-unsaturated derivative. This

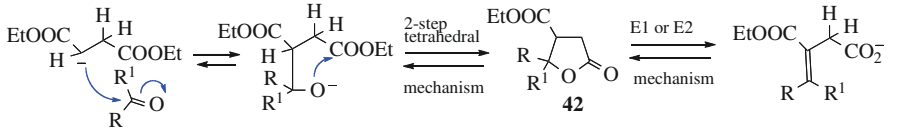
reaction is sometimes called the *Claisen reaction*,[1177] an unfortunate usage since that name is more firmly connected to Reaction **16-85**. *Claisen condensation* is a better descriptor. Early reactions used hydroxide or an alkoxide base in water or alcohol solvents, where self-condensation was the major process. Under such conditions, the aldehyde or ketone was usually chosen for its lack of an α-proton. Much better control of the reaction was achieved when dialkylamide bases in aprotic solvents (e.g., ether or THF) were used. The reaction of *tert*-butyl acetate and LDA[1178] in hexane or more commonly THF at –78 °C gives the enolate anion of *tert*-butyl acetate,[1179] (Reaction **12-23**, e.g., although self-condensation is occasionally a problem even here). Additives play an important role in the LDA mediated enolization of esters[1180]. Subsequent reaction of a ketone provides a simple rapid alternative to the *Reformatsky Reaction* (**16-28**) as a means of preparing β-hydroxy *tert*-butyl esters. It is also possible for the α carbon of an aldehyde or ketone to add to the carbonyl carbon of a carboxylic ester, but this is a different reaction (**16-86**) involving nucleophilic substitution and not addition to a C=O bond. It can, however, be a side reaction if the aldehyde or ketone has an α hydrogen.

Transition metal mediated condensation of esters with aldehydes is known. The reaction of a thioester and an aryl aldehyde with $TiCl_4$—NBu_3, for example, gave a β-hydroxy thioester with good syn selectivity.[1181] Selenoamides [$RCH_2C(=Se)NR'_2$] react with LDA and then an aldehyde to give β-hydroxy selenoamides.[1182] The reaction of an α,β-unsaturated ester and benzaldehyde with a chiral Rh catalyst gave a β-hydroxy ester with good diastereoselectivity and good enantioselectivity.[1183]



Besides ordinary esters (containing an α hydrogen), the reaction can also be carried out with lactones and, as in Reaction **16-34**, with the γ position of α,β-unsaturated esters (vinylogy; Sec. 6.B). The enolate anion of an amide can be condensed with an aldehyde.[1184] Thioesters undergo aldol-type condensations.[1185]

For most esters, a much stronger base is needed than for aldol reactions; $(i\text{Pr})_2\text{NLi}$ (LDA, Sec. 8.F, category 7), Ph_3CNa and $LiNH_2$ are among those employed. However, esters of malonic and succinic acid react more easily, and such strong bases are not needed. For example, diethyl succinate and its derivatives condense with aldehydes and ketones in the presence of bases (e.g., NaOEt, NaH, or $KOCMe_3$). This reaction is called the *Stobbe condensation*.[1186] One of the ester groups (sometimes both) is hydrolyzed in the course of the reaction. The following mechanism accounts for (1) the fact the succinic esters react so much better than others; (2) one ester group is always cleaved; and (3) the alcohol is not the product but the alkene. In addition, intermediate lactones (**42**) have been isolated from the mixture.[1187] The *Stobbe condensation* has been extended to di-*tert*-butyl esters of glutaric acid.[1188] The boron-mediated reaction is known.[1189]

The intramolecular reaction of an aldehyde–carboxylic acid in the presence of triethylamine and a pyridinium salt led to the ring-forming condensation reaction, followed by formation of a β-lactone.[1190]

Amides participate in this condensation reaction, reacting with aldehydes in the presence of a Ba catalyst to give a β-hydroxy amide derivative.[1191] The reaction of an amide with LDA in the presence of an acyl silane, followed by reaction with an alkyl halide, leads to the β-hydroxy amide with the additional alkyl group at the β-carbon.[1192]

Chiral additives (e.g., diazaborolidines) can be added to an ester, and subsequent treatment with a base, and then an aldehyde leads to a chiral β-hydroxy ester.[1193] A variety of chiral amide or oxazolidinone derivatives have been used to form amide linkages to carboxylic acid derivatives. These chiral auxiliaries lead to chirality transfer from the enolate anion of such derivatives, in both alkylation reactions and acyl substitution reactions with aldehydes and ketones. The so-called *Evans auxiliaries* (**43**–**45**) are commonly used and give good enantioselectivity.[1194] A variation is the magnesium halide-catalyzed anti-aldol reaction of chiral *N*-acylthiazolidinethiones (see **46**).[1195] The use of chiral *N*-acyloxazolidinthiones with $TiCl_4$ and sparteine also gave good selectivity in the acyl addition.[1196] Chiral diazaboron derivatives have also been used to facilitate the condensation of a α-phenylthio ester with an aldehyde.[1197]

The condensation of an ester enolate and a ketone[1198] can be used as part of a *Robinson annulation*-like sequence (see Reaction **16-34**).

16-37 The Henry Reaction[1199]

$$CH_3NO_2 + HCHO \xrightarrow{^-OH} HOCH_2CH_2NO_2$$

The classical condensation of an aliphatic nitro compound with an aldehyde or ketone is usually called the *Henry reaction*[1200] or the *Kamlet reaction*, and is essentially a nitro aldol reaction. A variety of conditions have been reported, including the use of a recoverable polymer catalyst,[1201] a silica catalyst,[1202] a tetraalkylammonium hydroxide,[1203] proazaphosphatranes,[1204] and it has been done in an aqueous media[1205] or an ionic liquid.[1206] A solvent-free *Henry reaction* was reported in which a nitroalkane and an aldehyde were reacted on KOH powder.[1207] A solvent-free microwave assisted reaction was reported.[1208] Potassium phosphate has been used with nitromethane and aryl aldehydes.[1209] The *Henry reaction* has been done using $ZnEt_2$ and 20% ethanolamine.[1210] A gel-entrapped base has been used to catalyze this reaction.[1211] Biocatalysts have been used.[1212]

Catalytic enantioselective *Henry reactions* are known,[1213] including the use of a chiral Cu,[1214] Zn,[1215] Nd,[1216] or Ti catalyst.[1217] The *Henry reaction* of nitromethane and a chiral aldehyde under high pressure gives the β-nitro alcohol with excellent

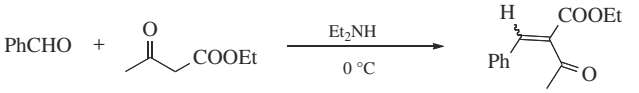
enantioselectivity.[1218] Enantioselective nitro–aldol reactions are catalyzed by organocatalysts (e.g., Cinchona alkaloids[1219] or other organocatalysts).[1220]

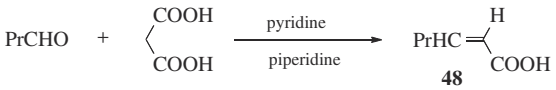


A variation of this reaction converts nitro compounds to nitronates [$RCH{=}N^{+}(OTMS){-}O^{-}$], which subsequently react with aldehydes in the presence of a Cu catalyst to give the β-nitro alcohol.[1221] aza-*Henry reactions* condense nitroalkanes with imine derivatives, and the resulting amino nitro compounds are formed with good enantioselectivity in the presence of organocatalysts[1222] or Brønsted acid catalysts.[1223] Aza-*Henry products* are also formed by the reaction of amines with activated unsaturated compounds.[1224]

16-38 The Knoevenagel Reaction

Bis(ethoxycarbonyl)methylene-de-oxo-bisubstitution, and so on

The condensation of aldehydes or ketones, usually not containing an α hydrogen, with compounds of the form $Z{-}CH_2{-}Z'$ or $Z{-}CHR{-}Z'$ is called the *Knoevenagel reaction*.[1225] Both Z and Z' may be CHO, COR, CO_2H, CO_2R, CN, NO_2, SOR, SO_2R, SO_2OR, or similar groups. The presence of two electron-withdrawing groups makes the α-proton much more acidic (Table 8.1 in Sec. 8.A.i), and such compounds have a significantly higher enol content.[1226] When $Z = CO_2H$, decarboxylation of the product often takes place *in situ*.[1227] As shown in the example, the reaction of β-keto esters and aldehydes to give **47** is promoted by diethylamine at 0 °C. Nitroalkanes,[1199] as well as β-keto sulfoxides,[1228] undergo the reaction.



47

As with Reaction **16-34**, these reactions have sometimes been mediated by an acid catalyst.[1229] Ionic liquid solvents have been used,[1230] and heating on quaternary

ammonium salts without solvent leads to a *Knoevenagel reaction*.[1231] Other solvent-free reactions are known.[1232] Ultrasound has been used to promote the reaction,[1233] and it has also been done using microwave irradiation[1234] or on silica,[1235] with microwave irradiation. Another solid-state variation is done on moist LiBr,[1236] heating with sodium carbonate and molecular sieves 4 Å promotes the reaction,[1237] as do zeolites.[1238] High-pressure conditions have been used.[1239] Transition metal compounds of Pd,[1240] Sm[1241] Ce,[1242] Ti,[1243] or Bi[1244] have been used to promote the *Knoevenagel reaction*.

With most of these reagents the alcohol is not isolated (only the alkene) *if* the alcohol has a hydrogen in the proper position,[1245] but with a careful workup the alcohol may be the major product. With suitable reactants, the *Knoevenagel reaction*, like the aldol condensation (**16-34**), has been carried out diastereoselectively[1246] and enantioselectively.[1247] When the reactant is of the form ZCH_2Z', aldehydes react much better than ketones and few successful reactions with ketones have been reported. However, it is possible to get good yields of the alkene from the condensation of diethyl malonate [$CH_2(CO_2Et)_2$] with ketones, as well as with aldehydes, if the reaction is run with $TiCl_4$ and pyridine in THF.[1248] In reactions with ZCH_2Z', the catalyst is most often a secondary amine (piperidine is the most common, but see formation of **47**), but many other catalysts have been used. Alkoxides are also common catalysts. When the catalyst is pyridine (to which piperidine may or may not be added) the reaction is known as the *Doebner modification* of the *Knoevenagel reaction* and the product is usually the conjugated acid (**48**). Microwave-induced *Doebner condensation* reactions are known.[1249]

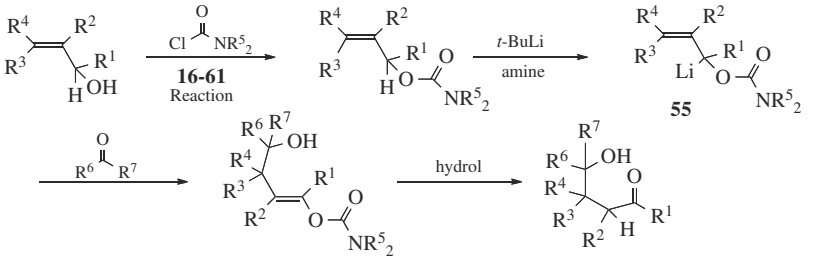
A number of special applications of the *Knoevenagel reaction* follow:

1. The dilithio derivative of *N*-methanesulfinyl-*p*-toluidine[1250] (**49**) adds to aldehydes and ketones to give, after hydrolysis, the hydroxysulfinamides (**50**). Subsequent heating leads to a stereospecific syn eliminations to give an alkene.[1251] The reaction is thus a method for achieving the conversion $RR'CO \rightarrow RR'C{=}CH_2$ and represents an alternative to the *Wittig reaction*.[1252] Note that sulfones with an amide group at the α-position, $[ArSO_2CH(R)N(R)C{=}O]$ react with ketones via acyl addition in the presence of SmI_2.[1253]



2. The reaction of ketones with tosylmethylisocyanide (**51**) gives different products,[1254] depending on the reaction conditions. When the reaction is run with potassium *tert*-butoxide in THF at –5 °C, one obtains (after hydrolysis) the normal *Knoevenagel* product (**52**), except that the isocyano group has been hydrated (Reaction **16-97**).[1255] With the same base but with 1,2-dimethoxyethane (DME) as solvent the product is the nitrile (**53**).[1256] When the ketone is treated with **51** and thallium(I) ethoxide in a 4: 1 mixture of absolute ethanol and DME at room temperature, the product is a 4-ethoxy-2-oxazoline (**54**).[1257] Since **53** can be hydrolyzed to a carboxylic acid[1198] and **54** to an α-hydroxy aldehyde,[1257] this versatile reaction provides a means for achieving the conversion of RCOR′ to $RCHR'CO_2H$, RCHR′CN, or RCR′(OH)CHO. The conversions to RCHR′COOH and to RCHR′CN[1258] have also been carried out with certain aldehydes (R′ = H).

3. Aldehydes and ketones (RCOR′) react with α-methoxyvinyllithium [CH_2=C(Li)OMe] to give hydroxy enol ethers [RR′C(OH)C(OMe)=CH_2], which are easily hydrolyzed to acyloins [RR′C(OH)COMe].[1259] In this reaction, the CH_2=C(Li)OMe is a synthon for the unavailable H_3C—C=O,[1260] and is termed an *acyl anion equivalent*. The reagent also reacts with esters (RCOOR′) to give RC(OH)(COMe=CH_2)$_2$. A synthon for the Ph—C=O ion is PhC(CN)OSiMe_3, which adds to aldehydes and ketones (RCOR′) to give, after hydrolysis, the α-hydroxy ketones [RR′C(OH)COPh].[1261]
4. Lithiated allylic carbamates (**55**) (prepared as shown) react with aldehydes or ketones (R^6COR^7), in a reaction accompanied by an allylic rearrangement, to give (after hydrolysis) γ-hydroxy aldehydes or ketones.[1262] The reaction is called *the homoaldol reaction*, since the product is a homologue of the product of Reaction **16-34**. The reaction has been performed enantioselectively.[1263]

5. The lithium salt of an active hydrogen compound adds to the lithium salt of the tosylhydrazone of an aldehyde to give product **56**. If X = CN, SPh, or SO_2R, **56** spontaneously loses N_2 and LiX to give the alkene **57**. The entire process is done in one reaction vessel: The active hydrogen compound is mixed with the tosylhydrazone and the mixture is treated with (*i*Pr)$_2$NLi to form both salts at once.[1264] This process is another alternative to the *Wittig reaction* for forming double bonds.

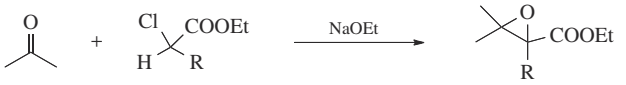
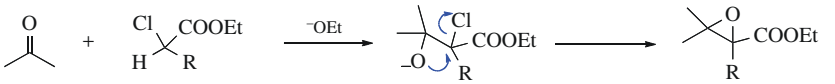
16-39 The Perkin Reaction

α-Carboxyalkylidene-de-oxo-bisubstitution



The condensation of aromatic aldehydes with anhydrides is called the *Perkin reaction*.[1265] When the anhydride has two α hydrogen atoms (as shown), dehydration almost always occurs; the β-hydroxy acid salt is rarely isolated. In some cases, anhydrides of the form $(R_2CHCO)_2O$ have been used, and then the hydroxy compound is the product since dehydration cannot take place. The base in the *Perkin reaction* is nearly always the salt of the acid corresponding to the anhydride. Although the Na and K salts have been most frequently used, higher yields and shorter reaction times have been reported for the Cs salt.[1266] Besides aromatic aldehydes, their vinylogs (ArCH=CHCHO) also give the reaction (see Sec. 6.B). Otherwise, the reaction is not suitable for aliphatic aldehydes.[1267]



OS **I**, 398; **II**, 61, 229; **III**, 426.

16-40 Darzens Glycidic Ester Condensation

(2+1) *OC,CC-cyclo*-α-Alkoxycarbonylmethylene-addition

Aldehydes and ketones condense with α-halo esters in the presence of bases to give α,β-epoxy esters, called *glycidic esters*. This is called *the Darzens condensation*.[1268] The reaction consists of an initial *Knoevenagel-type* Reaction (**16-38**), followed by an internal S_N2 Reaction (**10-9**)[1269]:

Although the intermediate halo alkoxide is generally not isolated,[1270] it has been done, not only with α-fluoro esters (since fluorine is such a poor leaving group in nucleophilic substitutions), but also with α-chloro esters.[1271] This is only one of several types of evidence that rule out a carbene intermediate.[1272] Sodium ethoxide is often used as the base, but other bases, including sodium amide, are sometimes used. Aromatic aldehydes and ketones give good yields. The reaction can be made to give good yields (~ 80%) with simple aliphatic aldehydes, as well as with aromatic aldehydes and ketones, by treatment of the α-halo ester with the base lithium bis(trimethylsilyl)amide [$LiN(SiMe_3)_2$] in THF at

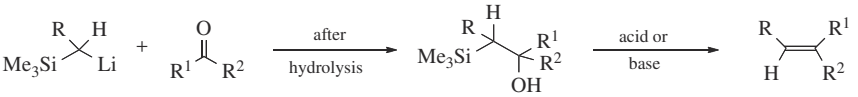
–78 °C (to form the conjugate base of the ester) and addition of the aldehyde or ketone to this solution.[1273] If a preformed dianion of an α-halo carboxylic acid ($Cl^-CRCO_2^-$) is used instead, α,β-epoxy acids are produced directly.[1274] The *Darzens reaction* has also been carried out on α-halo ketones, α-halo nitriles,[1275] α-halo sulfoxides[1276] and sulfones,[1277] α-halo N,N-disubstituted amides,[1278] α-halo ketimines,[1279] and even on allylic[1280] and benzylic halides. Phase-transfer catalysis has been used.[1281] Note that the reaction of a β-bromo-α-oxo ester and a *Grignard reagent* leads to the glycidic ester.[1282] Acid-catalyzed *Darzens reactions* have also been reported.[1283] (see also, Reaction **16-46**).

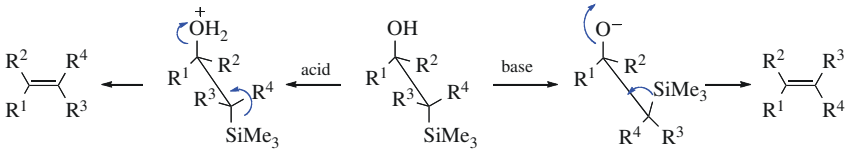


Diastereoselective *Darzens condensations* are possible.[1284] The *Darzens reaction* has been performed with good enantioselectivity,[1285] and chiral additives have proven to be effective.[1286] Chiral phase-transfer agents have been used to give epoxy ketones with modest enantioselectivity.[1287]

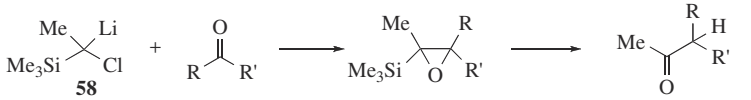
Glycidic esters can easily be converted to aldehydes (Reaction **12-40**). The reaction has been extended to the formation of analogous aziridines by treatment of an imine with an α-halo ester or an α-halo N,N-disubstituted amide and *t*-BuOK in the solvent 1,2-dimethoxyethane.[1288] However, yields were not high.

OS **III**, 727; **IV**, 459, 649.

16-41 The Peterson Alkenylation Reaction



Alkylidene-de-oxo-bisubstitution



In the *Peterson alkenylation reaction*[1289], the lithio (or sometimes magnesio) derivative of a trialkylsilane adds to an aldehyde or ketone to give a β-hydroxysilane, which spontaneously eliminates water, or can be made to do so by treatment with acid or base, to produce an alkene. This reaction is still another alternative to the *Wittig reaction* (**16-44**), and is sometimes

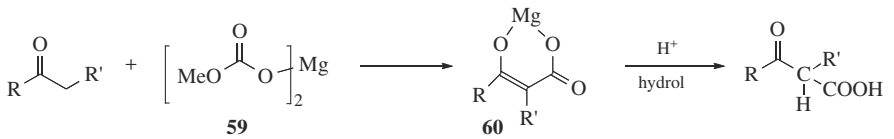
called the *silyl–Wittig reaction*.[1290] The R group can also be a COOR group, in which case the product is an α,β-unsaturated ester,[1291] or an SO_2Ph group, in which case the product is a vinylic sulfone.[1292] The stereochemistry of the product can often be controlled by whether an acid or a base is used to achieve elimination. The role of Si—O interactions has also been examined.[1293] Use of a base generally gives syn elimination (Ei mechanism, see Sec. 17.C.i), while an acid usually results in anti elimination (E2 mechanism, see Sec. 17.A.i).[1294] Samarium(II) iodide in HMPA has also been used for elimination of the hydroxy sulfone.[1295]

When aldehydes or ketones are treated with reagents of the form **58**, the product is an epoxy silane (Reaction **16-46**), which can be hydrolyzed to a methyl ketone.[1296] For aldehydes, this is a method for converting RCHO to a methyl ketone (RCH_2COMe).

58



The reagents $Me_3SiCHRM$ (M = Li or Mg) are often prepared from $Me_3SiCHRCl$[1297] (by Reaction **12-38** or **12-39**), but they have also been made by Reaction **12-22** and other procedures.[1298] Lithio alkenylsilanes have been used for this reaction.[1299]

A new version of the reaction has been developed, reacting $Me_3SiCH_2CO_2Et$ with an aldehyde and a catalytic amount of CsF in DMSO.[1300] A seleno-amide derivative has been used in a similar manner.[1301]

There are no references in *Organic Syntheses*, but see OS **VIII**, 602, for a related reaction.

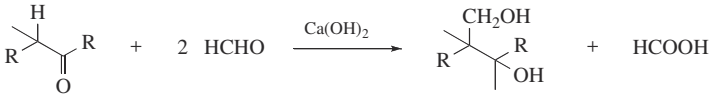
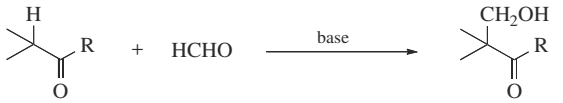
Ketones of the form $RCOCH_3$ and $RCOCH_2R'$ can be carboxylated indirectly by treatment with magnesium methyl carbonate (**59**).[1302] Because formation of the chelate (**60**) provides the driving force of the reaction, carboxylation cannot be achieved at a disubstituted α position. The reaction has also been performed on CH_3NO_2, on compounds of the form RCH_2NO_2[1303] and on certain lactones.[1304] Direct carboxylation has been reported in a number of instances. Ketones have been carboxylated in the α position to give β-keto acids.[1305] The base here was lithium 4-methyl-2,6-di-*tert*-butylphenoxide.



Ketones ($RCOCH_2R'$), as well as other active hydrogen compounds, undergo base-catalyzed addition to CS_2[1306] to give a dianion intermediate ($RCOC^-R'CSS^{2-}$), which can be dialkylated with a halide (R^2X) to produce α-dithiomethylene ketones [$RCOCR'{=}C(SR^2)_2$].[1307] Compounds of the form ZCH_2Z' also react with bases and CS_2 to give analogous dianions.[1308]

Although reactions with N=O derivatives do not formally fall into this category of reactions, it is somewhat related. Nitroso compounds react with activated nitriles in the presence of LiBr and microwave irradiation to give a cyano imine [$ArN{=}C(CN)Ar$].[1309] This transformation has been called the *Ehrlich–Sachs reaction*.[1310]



OS **VII**, 476. See also, OS **VIII**, 578.

16-43 Tollens' Reaction

O-Hydro-*C* (β-hydroxyalkyl)-addition

In the *Tollens' reaction*, an aldehyde or ketone containing an α hydrogen is treated with formaldehyde in the presence of $Ca(OH)_2$ or a similar base. The first step is a mixed-aldol reaction (**16-34**).

The reaction can be stopped at this point, but more often a second equivalent of formaldehyde is permitted to reduce the newly formed aldol to a 1,3-diol, in a *crossed-Cannizzaro Reaction* (**19-81**). If the aldehyde or ketone has several α hydrogen atoms, they can all be replaced. An

16-44 The Wittig Reaction

Alkylidene-de-oxo-bisubstitution

In the *Wittig reaction*, an aldehyde or ketone is treated with a *phosphorus ylid* (a *phosphorane*; also spelled ylide) to give an alkene.[1311] The conversion of a carbonyl compound to an alkene with a phosphorus ylid is called the *Wittig reaction*. Phosphorus ylids are usually prepared by treatment of a phosphonium salt with a base,[1312] and phosphonium salts (**61**) are usually prepared from a triaryl phosphine and an alkyl halide (Reaction **10-31**):

The reaction of triphenylphosphine and an alkyl halides is facilitated by the use of microwave irradiation.[1313] Indeed, the *Wittig reaction* itself is assisted by microwave irradiation.[1314] Phosphonium salts are also prepared by addition of phosphines to *Michael alkenes* (like Reaction **15-8**) and in other ways.

The phosphonium salts are most often converted to the ylids by treatment with a strong base (e.g., butyllithium, sodium amide,[1315] sodium hydride, or a sodium alkoxide, though weaker bases can be used if the salt is acidic enough. In some cases, and excess of fluoride ion is sufficient.[1316] For $(Ph_3P^+)_2CH_2$, sodium carbonate is a strong enough base.[1317] When the base used does not contain lithium, the ylid is said to be prepared under "salt-free" conditions[1318] because the lithium halide (where the halide counterion comes from

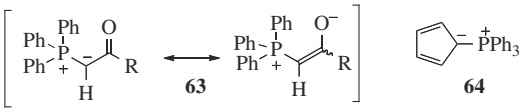
the phosphonium salt) is absent. *Wittig reactions* can be done in aqueous media in the presence of surfactants.[1319]

When the phosphorus ylid reacts with the aldehyde or ketone to form an alkene, a phosphine oxide is also formed. When triphenylphosphine is used to give $Ph_3P{=}CRR'$, for example, the byproduct is triphenylphosphine oxide (Ph_3PO), which is sometimes difficult to separate from the other reaction products. Other triarylphosphines[1320] and trialkylphosphines[1321] have been used. Phosphines that have an α-hydrogen should be avoided, so that reaction with the chosen alkyl halide will lead to a phosphonium salt (**61**) with the α-proton at the desired position. This limitation is essential if a specific ylid is to be formed from the alkyl halide precursor. The *Wittig reaction* has been carried out with polymer-supported ylids.[1322] It has also been done on silica gel.[1323] Polymer-bound aryldiphenylphosphino compounds[1324] have been used in reactions with alkyl halides to complete a *Wittig reaction.*

If an alkyl halide is viewed as the starting material (alkyl halide phosphonium salt → phosphorus ylid → alkene), the halogen-bearing carbon of an alkyl halide must contain at least one hydrogen, as in **62** (for deprotonation at the phosphonium salt stage).



62

The reaction is very general.[1325] The aldehyde or ketone may be aliphatic, alicyclic, or aromatic (including diaryl ketones). *Wittig reactions* are known in which the ylid and/or the carbonyl substrate contain double or triple bonds; various functional groups may be present (e.g., OH, OR, NR_2, aromatic nitro or halo, acetal, amide,[1326] or even ester groups).[1327] Note, however, that a *Wittig reaction* has been reported in which the carbonyl group of an ester was converted to a vinyl ether.[1328] An important advantage of the *Wittig reaction* is that the *position* of the new double bond is always certain, in contrast to the result in most of the base-catalyzed condensations (Reactions **16-34**–**16-43**). Ylids have been shown to react with lactones, however, to form ω-alkenyl alcohols.[1329] β-Lactams have also been converted to alkenyl-azetidine derivatives using phosphorus ylids.[1330] Double or triple bonds *conjugated* with the carbonyl also do not interfere, the attack being at the C=O carbon. The carbonyl partner can be generated *in situ*, in the presence of an ylid; the reaction of an alcohol with a mixture of an oxidizing agent and an ylid generates an alkene. Oxidizing agents used in this manner include $BaMnO_4$,[1331] MnO_2,[1332] and $PhI(OAc)_2$.[1333]

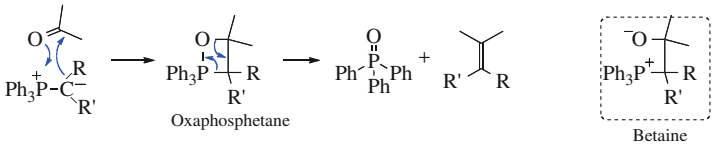
Weinreb amides (Reaction **16-82**) can be converted to the corresponding aldehyde via the *Wittig reaction.*[1334]

As noted above, the phosphorus ylid may also contain double or triple bonds and certain functional groups. Simple ylids (R, R′ = hydrogen or alkyl) are highly reactive, reacting with oxygen, water, hydrohalic acids, and alcohols, as well as carbonyl compounds and carboxylic esters, so the reaction must be run under conditions where these materials are absent. When an electron-withdrawing group (e.g., COR, CN, CO_2R, CHO) is present in the α position, the ylids are much more stable, because the charge on the carbon is delocalized by

resonance as in **63**. Such ylids react readily with aldehydes, but slowly or not at all with ketones.[1335] In extreme cases (e.g., **64** where the carbanion unit is part of the aromatic cyclopentadienyl anion), the ylid does not react with ketones *or* aldehydes. Besides these groups, the ylid may contain one or two α halogens[1336] or

an α OR or OAr group. In the latter case, the product is an enol ether, which can be hydrolyzed (Reaction **10-6**) to an aldehyde,[1337] so that this reaction is a means of achieving the conversion RCOR′ → RR′CHCHO.[1338] However, the ylid may not contain an α nitro group. If the phosphonium salt contains a potential leaving group (e.g., Br or OMe) in the β position, treatment with a base gives elimination, instead of the ylid:



However, a β COO^- group may be present, and the product is a β,γ-unsaturated acid:[1339] This is the only convenient way to make these compounds, since elimination by any other route gives the thermodynamically more stable α,β-unsaturated isomers. This is an illustration of the utility of the *Wittig* method for the specific location of a double bond. Another illustration is the conversion of cyclohexanones to alkenes containing exocyclic double bonds, for example:[1340]

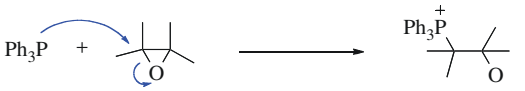
Still another example is the formation of *anti-Bredt* bicycloalkenones[1341] (see Sec. 4.Q.iii). As indicated above, α,α'-dihalophosphoranes can be used to prepare 1,1-dihaloalkenes. Another way to prepare haloalkenes[1342] is to treat the carbonyl compound with a mixture of CX_4 (X = Cl, Br, or I) and triphenylphosphine, either with or without the addition of zinc dust, which allows less Ph_3P to be used.[1343] Aryl aldehydes react with these dihalophosphoranes to give aryl alkynes after treatment of the initially formed vinyl halide with potassium *tert*-butoxide.[1344]

The mechanism[1345] of the key step of the *Wittig reaction* is as follows:[1346]



The energetics of ylid formation and their reaction in solution has been studied.[1347] For many years it was assumed that a diionic compound, called a *betaine*, is an intermediate on the pathway from the starting compounds to the oxaphosphetane, but it has been argued that there is little evidence for it.[1348] However, "betaine" precipitates have been isolated in certain *Wittig reactions*,[1349] although these are betaine–lithium halide adducts, and might just as well have been formed from the oxaphosphetane as from a true betaine.[1350] There is one report of an observed betaine lithium salt during the course of a *Wittig reaction*.[1351] An X-ray structure was determined for a *gauche* betaine from a thio-*Wittig reaction*.[1352] In contrast, there is much evidence for the presence of the oxaphosphetane intermediates, at least with unstable ylids. For example, ^{31}P NMR spectra taken of the reaction mixtures at low temperatures[1353] are compatible with an oxaphosphetane structure that persists for some time but not with a tetra-coordinated phosphorus species. Since a betaine, an ylid, and a phosphine oxide all have tetracoordinated phosphorus, these species could not be causing the spectra, leading to the conclusion that an oxaphosphetane intermediate is present in the solution. In certain cases, oxaphosphetanes have been isolated.[1354] It has even been

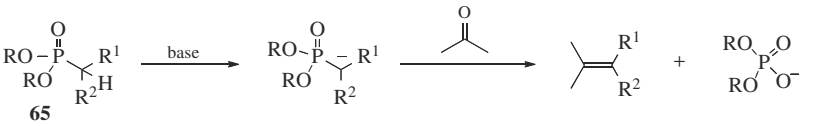
possible to detect cis and trans isomers of the intermediate oxaphosphetanes by NMR spectroscopy.[1355] According to this mechanism, an optically active phosphonium salt ($RR^1R^2P^+CHR^2$) should retain its configuration all the way through the reaction, and it should be preserved in the phosphine oxide (RR^1R^2PO). This has been shown to be the case.[1356]



Note that the proposed betaine intermediates can be formed, in a completely different manner, by nucleophilic substitution by a phosphine on an epoxide (**10-35**):

Betaines formed in this way can then be converted to the alkene. This is one reason why betaine intermediates were long accepted in the *Wittig reaction*. It is also noteworthy that stable phosphonium enolate zwitterions have been formed by the reaction of an aryl aldehyde, a phosphine, and a propargylic ester.[1357]

Phosphorus is not the only key element used to produce useful ylids. Triphenylarsine[1358] has been used. Tellurium ylids have been prepared *in situ* from α-halo esters and $BrTeBu_2OTeBu_2Br$ and react with aldehydes to give conjugated esters.[1359]

The *Wittig reaction* has been carried out with phosphorus ylids other than phosphoranes, the most important being prepared from phosphonate esters (e.g., **65**).[1360]

65

This method, sometimes called the *Horner–Emmons*, *Wadsworth–Emmons*, *Wittig–Horner, or Horner–Wadsworth–Emmons reaction*,[1361] has several advantages over the use of phosphoranes, including selectivity.[1362] These ylids are more reactive than the corresponding phosphoranes, and when R^1 or R^2 is an electron-withdrawing group, these compounds often react with ketones that are inert to phosphoranes. High pressure has been used to facilitate this reaction.[1363] In addition, the phosphorus product is a phosphate ester, and hence soluble in water, unlike Ph_3PO, which makes it easy to separate it from the

alkene product. Phosphonates are also cheaper than phosphonium salts and can easily be prepared by the *Arbuzov reaction*:[1364]

Phosphonates have also been prepared from alcohols and $(ArO)_2P(=O)Cl$, NEt_3, and a $TiCl_4$ catalyst.[1365] The reaction of $(RO)_2P(=O)H$ and aryl iodides with a CuI catalyst leads to aryl phosphonates.[1366] Polymer-bound phosphonate esters have been used for olefination.[1367] Dienes are produced when allylic phosphonate esters react with aldehydes.[1368] Nucleophilicity parameters have been determined for phosphoryl-stabilized carbanions.[1369] A Zn promoted reaction is known using diprotic phosphonates.[1370] *Wittig reactions* of stabilized phosphorus ylids have also been done in water.[1371]

Stereoselective alkenylation reactions have been achieved using chiral additives[1372] or auxiliaries.[1373] Ylids formed from phosphine oxides $[Ar_2P(=O)CHRR']$, phosphonic acid bis(amides), $(R_2{}^2N)_2POCHRR^1]$,[1374] and alkyl phosphonothionates $[(MeO)_2PSCHRR^1]$,[1375] share some of these advantages. Reagents (e.g., $Ph_2POCH_2NR_2$') react with aldehydes or ketones (R^2COR^3) to give good yields of enamines ($R^2R^3C{=}CHNR$).[1376] (*Z*)-Selective reagents are also known,[1377] including the use of a di(2,2,2-trifluoroethoxy)phosphonate with KHMDS and 18-crown-6.[1378] An interesting intramolecular version of the *Horner–Emmons reaction* leads to alkynes.[1379] The reaction of a functionalized aldehyde (R—CHO) with $(MeO)_2POCHN_2$, leads to an alkyne (R—C≡CH).[1380]

Some *Wittig reactions* give the (*Z*)-alkene; some the (*E*), and others give mixtures. The question of which factors determine the stereoselectivity has been much studied.[1381] It is generally found that ylids containing stabilizing groups or formed from trialkylphosphines give (*E*)-alkenes. The origin of the (*E*) selectivity in salt-free stabilized ylids may be related to dipole–dipole interactions.[1382] The energy of the elimination transition state must also be taken into account.[1383] It has been shown that ylids formed from triarylphosphines and not containing stabilizing groups often give (*Z*) or a mixture of (*Z*)- and (*E*)-alkenes.[1384] One explanation for this[1356] is that the reaction of the ylid with the carbonyl compound is a [2+2]-cycloaddition, which in order to be concerted must adopt the $[\pi 2_s + \pi 2_a]$-pathway. As discussed in Reaction **15-63**, this pathway leads to the formation of the more sterically crowded product, in this case the (*Z*)-alkene. If this explanation is correct, it is not easy to explain the predominant formation of (*E*) *p*roducts from stable ylids, but (*E*) compounds are of course generally thermodynamically more stable than the (*Z*) isomers, and the stereochemistry seems to depend on many factors.

The (*E*/*Z*) ratio of the product can often be changed by a change in solvent or by the addition of salts.[1385] Another way of controlling the stereochemistry of the product is by use of the aforementioned phosphonic acid bis(amides). In this case, the betaine (**66**) does form and when treated with water gives the β-hydroxyphosphonic acid bis(amides) (**67**), which can be crystallized and then cleaved to $R^1R^2C{=}CR^3R^4$ by refluxing in benzene or toluene in the presence of silica gel.[1374] β-Hydroxy products (**67**) are generally formed as mixtures of diastereomers, and these mixtures can be separated by recrystallization. Each diastereomer will give one of the two isomeric alkenes. Optically active phosphonic acid bis(amides) have been used to give optically active alkenes.[1386] Another method of controlling the stereochemistry of the alkene [to obtain either the (*Z*)- or (*E*)-isomer] starting with a phosphine oxide (Ph_2POCH_2R) has been reported.[1387]

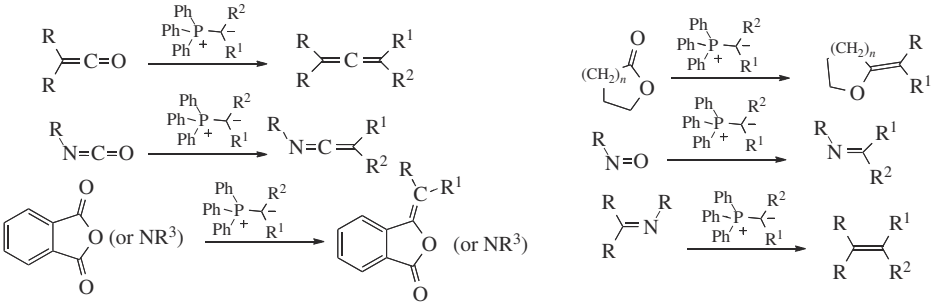
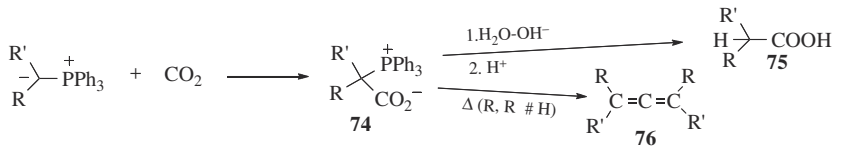
In reactions where the betaine–lithium halide intermediate is present, it is possible to extend the chain further if a hydrogen is present α to the phosphorus. For example, reaction of ethylidenetriphenylphosphorane with heptanal at −78 °C gave **68**, and subsequent treatment with butyllithium gave the ylid, (**69**). Treatment of **69** with an aldehyde (R′CHO) gave the intermediate (**70**) that gave, after workup, **71**[1388] stereoselectively. Alkoxide **69** also reacts with other electrophiles. For example, treatment of **69** with NCS or $PhICl_2$ gave the vinylic chloride (RCH=CMeCl) stereoselectively: NCS gave the cis and $PhICl_2$ the trans-isomer.[1389] The use of Br_2 and $FClO_3$ (several explosions[1390] have been observed with this reagent) gives the corresponding bromide or fluoride, respectively.[1391] Reactions of **69** with electrophiles have been called *scoopy reactions* (α *s*ubstitution plus *c*arbonyl alkenylation via β-*o*xido *p*hosphorus *ylid*s).[1392]



The reaction of a phosphonate ester, DBU, NaI, and HMPA with an aldehyde leads to a conjugated ester with excellent (*Z*)-selectivity.[1393] A (*Z*)-selective reaction was reported using a trifluoroethyl phosphonate in a reaction with an aldehyde and potassium *tert*-butoxide.[1394]

The *Wittig reaction* has been carried out intramolecularly, to prepare rings containing from 5 to 16 carbons,[1395] both by single-ring closure to give alkenes (e.g., **70**), or by double-ring closure, as in the conversion of **71** to **72**).[1396]



70 **71** **72**

The *Wittig reaction* has proved very useful in the synthesis of natural products, some of which are quite difficult to prepare in other ways.[1397]

Phosphorus ylids also react in a similar manner with the C=O bonds of ketenes,[1398] isocyanates,[1399] certain anhydrides[1400] lactones,[1401] and imides,[1402] the N=O of nitroso groups, and the C=N of imines,[1403] as shown in the composite reaction. Phosphorus ylids react with carbon dioxide to give the isolable salts (**74**),[1404] which can be hydrolyzed to the carboxylic acids (**75**) (thus achieving the conversion RR′CHX → RR′CHCOOH) or (if neither R nor R′ is hydrogen) dimerized to allenes (**76**).

Although phosphorus ylids are most commonly used for alkenylation reactions, nitrogen ylids can occasionally be used. However, nitrogen ylids are often difficult to form, are unstable and highly reactive. The reaction of *N*-benzyl-*N*-phenylpiperidinium bromide with base to give an N-ylid is one example, and it reacted with benzaldehyde to form styrene.[1405] The structure has been determined for an intermediate in an *aza*-Wittig reaction.[1406] An *aza-Wittig reaction*[1407] has been used to prepare pyrrolines and tetrahydropyridines.[1408]

pyridine[1410] leads to the alkene. Dimethyltitanocene (Me_2TiCp_2), called the *Petasis reagent*, is a convenient and highly useful alternative to **77**.[1411] The mechanism of *Petasis olefination* has been examined.[1412] Both the *Tebbe* and the *Petasis reagent* give good results with ketones.[1413] An important feature of these new reagents is that carboxylic esters and lactones[1414] can be converted to the corresponding enol ethers in good yields. The enol ether can be hydrolyzed to a ketone (Reaction **10-6**), so this is also an indirect method for making the conversion $RCO_2R' \rightarrow RCOCH_3$ (see also, Reaction **16-82**). Conjugated esters are converted to alkoxy-dienes with this reagent.[1415] Lactams, including β-lactams, are converted with alkylidene cycloamines (alkylidene azetidines from β-lactams, which are easily hydrolyzed to β-amino ketones).[1416]

Besides stability and ease of preparation, another advantage of the Petasis reagent is that structural analogues can be prepared, including $Cp_2Ti(C_3H_5)_2$[1417] (C_3H_5 = cyclopropyl), $CpTi(CH_2SiMe_3)_3$,[1418] and $Cp_2TiMe(CH{=}CH_2)$.[1419] In another variation, 2 molar equivalents of $Cp_2Ti[P(OEt)_3]_2$ reacted with a ketone in the presence of 1,1-diphenylthiocyclobutane to give the alkenylcyclobutane derivative.[1420] An alternative Ti reagent was prepared using $TiCl_4$, Mg metal and dichloromethane, reacting with both ketones[1421] and esters[1422] to give alkenes or vinyl ethers, respectively. Alkenes are generated form ketones and alkyl iodides in the presence of a catalytic amount of $Cp_2Ti[POEt)_3]_2$.[1423]

Carboxylic esters undergo the conversion $C{=}O \rightarrow C{=}CHR$ (R = primary or secondary alkyl) when treated with $RCHBr_2$, Zn,[1424] and $TiCl_4$ in the presence of *N,N,N',N'*-tetramethylethylenediamine.[1425] Metal carbene complexes[1426] $R_2C{=}ML_n$ (L = ligand), where M is a transition metal (e.g., Zr, W, or Ta) have also been used to convert the C=O of carboxylic esters and lactones to CR_2.[1427] It is likely that the complex $Cp_2Ti{=}CH_2$ is an

intermediate in the reaction with the *Tebbe reagent*. Indeed, Ti carbenoids have been used to convert carbonyl groups to the corresponding alkene.[1428]

There are a few other methods for converting ketones or aldehydes to alkenes.[1429] Carbonyl compounds react with bis(iodozincio)methane to give alkenes.[1430] When a ketone is treated with CH_3CHBr_2/Sm/SmI_2, with a catalytic amount of $CrCl_3$, the alkene is formed.[1431] α-Halo esters also react with $CrCl_2$ in the presence of a ketone to give vinyl halides.[1432] Organozinc reagents have been used to convert carbonyl compounds to alkenes in the presence of Lewis acids.[1433] α-Diazo esters react with ketones in the presence of an iron catalyst to give the corresponding alkene.[1434] α-Diazo silylalkanes react similarly in the presence of a Rh catalyst.[1435] Ketone olefination has been accomplished using methyltrioxorhenium.[1436] α-Halosulfones react with aldehydes in the presence of LiHMDS and $MgBr_2{}^{\bullet}OEt_2$ to give a vinyl chloride.[1437]

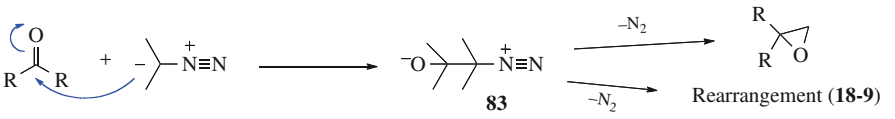
and ordinarily must be used as soon as it is formed, while **78** can be stored several days at room temperature. When diastereomeric epoxides can be formed, **79** usually attacks from the more hindered and **78** from the less-hindered side. Thus, 4-*tert*-butylcyclohexanone, treated with **78** gave exclusively **80** while **79** gave mostly **81**.[1442] Another difference in behavior between the two reagents is that with α,β-unsaturated ketones, **78** gives

only cyclopropanes (Reaction **15-64**), while **79** gives oxirane formation. Other sulfur ylids have been used in an analogous manner, to transfer CHR or CR_2.[1443] Other sulfur ylids convert aldehydes to epoxides.[1444] High yields have been achieved by the use of sulfonium ylids anchored to insoluble polymers under phase-transfer conditions.[1445] A solvent-free version of this reaction has been developed using powdered K *tert*-butoxide and $Me_3S^+I^-$.[1446] Note that treatment of epoxides with 2 equiv of $Me_2S{=}CH_2$ leads to allylic alcohols.[1447]

Chiral sulfur ylids[1448] have been prepared, giving the epoxide with good asymmetric induction,[1449] and chiral additives have also been used.[1450] Chiral Se ylids have been used in a similar manner.[1451]



The generally accepted mechanism for the reaction between sulfur ylids and aldehydes or ketone is formation of **82**, with displacement of the Me_2S leaving group by the alkoxide.[1452] This mechanism is similar to that of the reaction of sulfur ylids with C=C double bonds (Reaction **15-64**).[1453] The stereochemical difference in the behavior of **78** and **79** has been attributed to formation of the betaine (**82**) being reversible for **78**, but not for the less stable **79**, so that the more-hindered product is the result of kinetic control and the less hindered of thermodynamic control.[1454]

Phosphorus ylids do not give this reaction, but give **16-44** instead.

Aldehydes and ketones can also be converted to epoxides by treatment with a diazoalkane.[1455] Most commonly it is diazomethane, but an important side reaction is the formation of an aldehyde or ketone with one more carbon than the starting compound (Reaction **18-9**). The reaction can be carried out with many aldehydes, ketones, and quinones, usually with a Rh catalyst.[1456] A mechanism that accounts for both products follows:

Compound **83** or nitrogen-containing derivatives of it have sometimes been isolated.

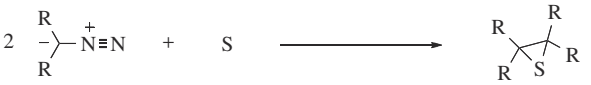
An alternative route to epoxides from ketones uses α-chloro sulfones and potassium *tert*-butoxide to give α,β-epoxy sulfones.[1457] A similar reaction was reported using KOH and 10% of a chiral phase-transfer agent, giving moderate enantioselectivity in the epoxy sulfone product.[1458]

Dihalocarbenes and carbenoids, which readily add to C=C bonds (Reaction **15-64**), do not generally add to the C=O bonds of ordinary aldehydes and ketones.[1459] See also, Reaction **16-91**.

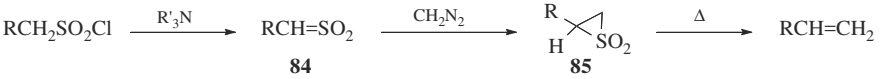
There is a report of a strained azetidinium ylid that has been used for epoxidation.[1460]

OS **V**, 358, 755.

16-47 The Formation of Aziridines from Imines



(1+2)*NC*,*CC-cyclo*-Methylene-addition



Just as sulfur ylids (e.g., **78**) react with the carbonyl of an aldehyde or ketone to give an epoxide, Te ylids react with imines to give an aziridine. The reaction of an allylic Te salt ($RCH{=}CHCH_2Te^+Bu_2\ Br^-$), with lithium hexamethyldisilazide in HMPA/toluene leads to the tellurium ylid via deprotonation. In the presence of an imine, the ylid add to the imine and subsequent displacement of Bu_2Te generates an aziridine with a pendant vinyl group.[1461] Catalytic aziridination of tosylimines was reported and mediated by arsonium ylids.[1462]

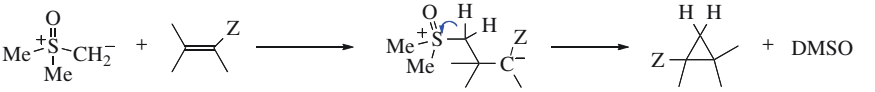
16-48 The Formation of Episulfides and Episulfones[1463]

Epoxides can be converted directly to episulfides by treatment with NH_4SCN and ceric ammonium nitrate.[1464] Diazoalkanes, treated with sulfur, give episulfides.[1465] It is likely that $R_2C{=}S$ is an intermediate, which is attacked by another molecule of diazoalkane, in a process similar to that shown in Reaction **16-46**. Thioketones *do* react with diazoalkanes to give episulfides,[1466] and have also been converted to episulfides with sulfur ylids.[1442] Carbenes (e.g., the dichlorocarbene from $CHCl_3$) and base react with thioketones to give an α,α-dichloro episufide.[1467]



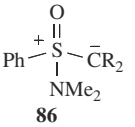
84 **85**

Alkanesulfonyl chlorides, when treated with diazomethane in the presence of a base (usually a tertiary amine), give episulfones (**85**).[1468] The base removes HCl from the sulfonyl halide to produce the highly reactive sulfene (**84**) (see Reaction **17-14**), which then adds CH_2. The episulfone can then be heated to give off SO_2 (see Reaction **17-20**), making the entire process a method for achieving the conversion $RCH_2SO_2Cl \rightarrow RCH{=}CH_2$.[1469]

OS **V**, 231, 877.

16-49 Cyclopropanation of Conjugated Carbonyl Compounds

Double-bond compounds that undergo the *Michael reaction* (**15-24**) can be converted to cyclopropane derivatives with sulfur ylids.[1470] Among the most common of these is dimethyloxosulfonium methylid (**78**),[1471]



78

which is widely used to transfer CH_2 to activated double bonds, but other sulfur ylids have also been used. A combination of DMSO and KOH in an ionic liquid converts conjugated

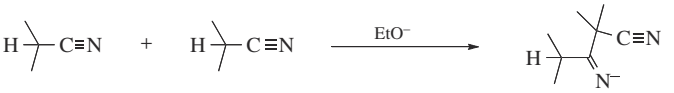
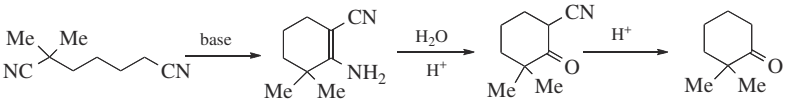
ketones to α,β-cyclopropyl ketones.[1472] Both CHR and CR_2 can be added in a similar manner with certain nitrogen-containing compounds. For example, ylids[1473] (e.g., **86**), add various groups to activated double bonds.[1474] Sulfur ylids react with allylic alcohols in the presence of MnO_2 and molecular sieve 4 Å to give the cyclopropyl aldehyde.[1475] Similar reactions have been performed with phosphorus ylids,[1476] with pyridinium ylids,[1477] and with the compounds $(PhS)_3CLi$ and $Me_3Si(PhS)_2CLi$.[1478] The reactions with ylids such as these of course involve nucleophilic acyl addition. Enantioselective cyclopropanation occurs in the presence of certain organocatalysts[1479] or chiral metal catalysts.[1480]



86



Other reagents can be used to convert an aldehyde or ketone to a cyclopropane derivative. Tellurium ylids react with conjugated imines to the cyclopropyl aldehyde after hydrolysis of the imine.[1481] Conjugated ketones react with $Cp_2Zr(CH_2{=}CH_2)$ and PMe_3 to give a vinyl cyclopropane derivative after treatment with aq H_2SO_4.[1482]

16-50 The Thorpe Reaction

N-Hydro-*C*-(α-cyanoalkyl)-addition

In the *Thorpe reaction*, the α carbon of one nitrile molecule is added to the CN carbon of another, so this reaction has analogies with the aldol reaction (**16-34**). The C=NH bond is, of course, hydrolyzable (Reaction **16-2**), so β-keto nitriles can be prepared in this manner. The *Thorpe reaction* can be done intramolecularly, in which case it

87

is called the *Thorpe–Ziegler reaction*.[1483] As with other cyclization methods, yields are high for 5–8-membered rings, fall off to about zero for rings of 9–13 members, but are high

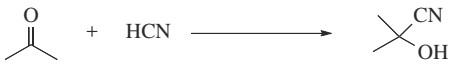
again for 14-membered and larger rings, if high-dilution techniques are employed. The product in the *Thorpe–Ziegler reaction* is not the imine, but the tautomeric enamine (e.g., **87**); if desired this can be hydrolyzed to an α-cyano ketone (Reaction **16-2**), which can in turn be hydrolyzed and decarboxylated (Reactions **16-4** and **12-40**). Other active-hydrogen compounds can also be added to nitriles.[1484]

OS **VI**, 932.

H. Other Carbon or Silicon Nucleophiles

16-51 Addition of Silanes

***O*-Hydro-*C*-alkyl-addition**

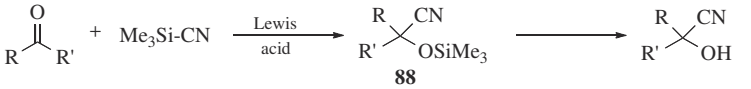


Allylic silanes react with aldehydes, in the presence of Lewis acids, to give a homoallylic alcohol.[1485] In the case of benzylic silanes, this addition reaction has been induced with Mg $(ClO_4)_2$ under photochemical conditions.[1486] Cyclopropylcarbinyl silanes add to acetals in the presence of TMSOTf to give a homoallylic alcohol.[1487] Allyltrichlorosilane adds an allyl group to an aldehyde in the presence of a cyclic urea and AgOTf.[1488] In a related reaction, allylic silanes react with acyl halides to produce the corresponding carbonyl derivative. The reaction of phenyl chloroformate, allyltrimethylsilane, and $AlCl_3$, for example, gave phenyl but-3-enoate.[1489] The use of chiral additives leads to the alcohol with good asymmetric induction.[1490]

Allylic silanes also add to imines, in the presence of $TiCl_4$, to give amines.[1491] Silanes also add to iminium salts, mediated by alkyltin compounds.[1492]

16-52 The Formation of Cyanohydrins

***O*-Hydro-*C*-cyano-addition**



The addition of HCN to aldehydes or ketones produces cyanohydrins.[1493] This is an equilibrium reaction, and for aldehydes and aliphatic ketones the equilibrium lies to the right; therefore the reaction is quite feasible, except with sterically hindered ketones (e.g., diisopropyl ketone). However, ketones (ArCOR) give poor yields, and the reaction cannot be carried out with ArCOAr since the equilibrium lies too far to the left. With aromatic

aldehydes the *benzoin condensation* (Reaction **16-55**) competes. With α,β-unsaturated aldehydes and ketones, 1,4-addition competes (Reaction **15-38**).

Ketones of low reactivity (e.g., ArCOR) can be converted to cyanohydrins by treatment with diethylaluminum cyanide (Et_2AlCN) (see OS **VI**, 307) or, indirectly, with cyanotrimethylsilane (Me_3SiCN)[1494] in the presence of a Lewis acid or base,[1495] followed by hydrolysis of the resulting *O*-trimethylsilyl cyanohydrin (**88**). Both direct formation of the cyanohydrin (hydrocyanation) and formation of the cyano-*O*-silyl ether have been carried out enantioselectively using chiral catalysts,[1496] including chiral organocatalysts,[1497] or chiral additives.[1498] Biocatalysts have been used.[1499] Hydrogen cyanide adds to aldehydes in the presence of a lyase to give the cyanohydrin with good enantioselectivity.[1500] Cyanohydrins have been formed using a lyase in an ionic liquid.[1501]

88

Solvent-free conditions have been reported using TMSCN, an aldehyde, and potassium carbonate.[1502] Amine *N*-oxides catalyze the reaction,[1503] as does tetrabutylammonium cyanide.[1504] Lithium perchlorate in ether facilitates this reaction,[1505] and LiCl catalyzes the reaction with Me_3SiCN.[1506] *N*-Heterocyclic carbenes catalyze the reaction,[1507] as do certain ionic liquids.[1508] With $MgBr_2$ as a catalyst, the reaction proceeds with good syn selectivity.[1509] Other useful catalysts include Pt[1510] Au,[1511] or Ti[1512] compounds, and $InBr_3$.[1513] The use of chiral additives leads to cyanohydrins with good asymmetric

induction.[1514] Chiral transition metal catalysts have been used to give *O*-trialkylsilyl cyanohydrins with good enantioselectivity.[1515] A venedium catalyst has been used in an ionic liquid.[1516] Note that the reaction of an aldehyde and TMSCN in the presence of aniline and a $BiCl_3$ catalyst leads to an α-cyano amine.[1517] Potassium cyanide and acetic anhydride react with an aldehyde in the presence of a chiral Ti catalyst to give an α-acetoxy nitrile.[1518]

Rather than direct reaction with an aldehyde or ketone, the bisulfite addition product is often treated with cyanide. The addition is nucleophilic and the actual nucleophile is ^{-}CN, so the reaction rate is increased by the addition of base.[1519] This was demonstrated by Lapworth in 1903, and consequently this was one of the first organic mechanisms to be known.[1520] This method is especially useful for aromatic aldehydes, since it avoids competition from the benzoin condensation. If desired, it is possible to hydrolyze the cyanohydrin *in situ* to the corresponding α-hydroxy acid. This reaction is important in the *Kiliani–Fischer* method of extending the carbon chain of a sugar.

A particularly useful variation of this reaction uses cyanide rather than HCN. α-Amino nitriles[1521] can be prepared in one step by the treatment of an aldehyde or ketone with NaCN and NH_4Cl. This is called the *Strecker synthesis*;[1522] and it is a special case of the *Mannich reaction* (**16-19**). Since the CN group is easily hydrolyzed to the acid, this is a convenient method for the preparation of α-amino acids. The reaction has also been carried out with $NH_3 + HCN$ and with NH_4CN. Salts of primary and secondary amines can be used instead of NH_4^+ to obtain *N*-substituted and *N,N*-disubstituted α-amino nitriles. Brønsted acids can also be used.[1523] Unlike Reaction **16-52**, the *Strecker synthesis* is useful for aromatic as well as aliphatic ketones. As in Reaction **16-52**, the Me_3SiCN method has been used; **76** is converted to the product with ammonia or an amine.[1524] The effect of pressure on the *Strecker synthesis* has been studied.[1525] A catalyst-free multi-component *Strecker reaction* is known.[1526] There is also an In mediated *Strecker reaction* in aq media.[1527] Enantioselective *Strecker syntheses* are possible using chiral ammonium salts[1528] and

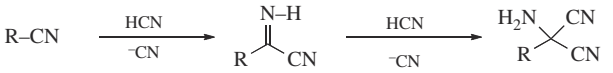
16-53 The Addition of HCN to C=N and C≡N Bonds

***N*-Hydro-*C*-cyano-addition**

Hydrogen cyanide adds to imines, *Schiff bases*, hydrazones, oximes, and similar compounds. Cyanide can be added to iminium ions to give α-cyano amines (**89**). As in Reaction **16-50**, the addition to imines has been carried out enantioselectively.[1533] Chiral ammonium salts have been used with HCN.[1534] Trimethylsilyl cyanide (TMSCN) reacts with *N*-tosyl



imines in the presence of $BF_3{\cdot}OEt_2$ to give the α-cyano *N*-tosyl amine.[1535] In the presence of a chiral Zr[1536] or Al[1537] catalyst, Bu_3SnCN reacts with imines to give α-cyanoamines enantioselectively. The imine can be formed *in situ b*y reaction of an aldehyde or ketone with an amine, in the present of TMSCN and a suitable promoter.[1538] The reaction of an imine and TMSCN gives the cyano amine with good enantioselectivity using a chiral Sc catalyst.[1539] Titanium catalysts have been used in the presence of a chiral *Schiff base*.[1540]

The addition of KCN to triisopropylbenzenesulfonyl hydrazones (**90**) provides an indirect method for achieving the conversion $RR'CO \rightarrow RR'CHCN$.[1541] The reaction is successful for hydrazones of aliphatic aldehydes and ketones.

$$\underset{\mathbf{90}}{RR'C{=}NN}HSO_2Ar + KCN \xrightarrow{MeOH} RR'CHCN \qquad Ar = 2,4,6(i\text{Pr})_3C_6H_2$$

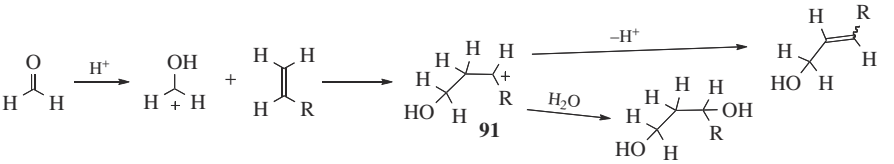
Hydrogen cyanide can also be added to the C≡N bond to give iminonitriles or α-amino-malononitriles.[1542]



The acylcyanation of imines is known, and enantioselectivity is achieved with a suitable catalyst.[1543]

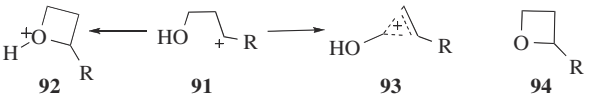
16-54 The Prins Reaction



The addition of an alkene to formaldehyde in the presence of an acid[1544] catalyst is called the *Prins reaction*.[1545] Three main products are possible; which one predominates depends on the alkene and the conditions. When the product is the 1,3-diol or the dioxane,[1546] the reaction involves addition to the C=C as well as to the C=O. The mechanism is one of electrophilic attack on both double bonds. The acid first protonates the C=O, and the resulting carbocation is attacked by the C=C to give **91**. The cation product **91** can

undergo loss of H^+ to give the alkene or add water to give the diol.[1547] It has been proposed that **91** is stabilized by neighboring-group attraction, with either the oxygen[1548] or a carbon[1549] stabilizing the charge (**92** and **94**, respectively). This stabilization is postulated to explain the fact that with 2-butenes[1550] and with cyclohexenes the addition is anti. A backside attack of H_2O on the three- or four-membered ring would account for it. Other products are obtained too, which can be explained on the basis of **92** or **93**.[1548,1549]

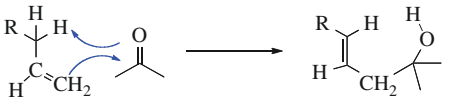
Additional evidence for the intermediacy of **92** is the finding that oxetanes (**94**) subjected to the reaction conditions, which would protonate **94** to give **92**, give essentially the same product ratios as the corresponding alkenes.[1551] An argument against the intermediacy of **92** and **93** is that not all alkenes show the anti-stereoselectivity mentioned above. Indeed, the stereochemical results are often quite complex, with syn, anti, and nonstereoselective addition reported, depending on the nature of the reactants and the reaction conditions.[1552] Since addition to the C=C bond is electrophilic, the reactivity of the alkene increases with alkyl substitution and *Markovnikov's rule* is followed. The dioxane product may arise from a reaction between the 1,3-diol and formaldehyde[1553] (**16-5**) or between **92** and formaldehyde. Racemization may occur in the *Prins cyclization* reaction by 2-oxonia-*Cope rearrangements* (see **18-32**) by way of a (*Z*)-oxocarbenium ion intermediate.[1554]

92 **91** **93** **94**

Iodine can promote the *Prins reaction*.[1555] Lewis acids (e.g., $SnCl_4$) also catalyze the reaction, in which case the species that adds to the alkenes is H_2C^+–O–$SnCl_4$.[1556] The reaction can also be catalyzed by peroxides, in which case the mechanism is probably a free radical one. Other transition metal complexes can be used to form homoallylic alcohols. A typical example is the reaction of methylenecyclohexane with an aryl aldehyde to give **95**.[1557]



95

Samarium iodide promotes this addition reaction.[1558] In a related reaction, simple alkene units add to esters in the presence of sodium and liquid ammonia to give an alcohol.[1559] Dienes react with alcohols in the presence of a transition metal compound, to give alkenyl alcohols.[1560] Allenes also add to aldehydes.[1561] Enynes undergo *Prins cyclization* with Au catalysts.[1562]

Structural variations in the alkene lead to different products. Homoallylic alcohols react with aldehydes in the presence of Montmorillonite-KSF clay to give 4-hydroxytetrahydropyrans.[1563] A variation of this reaction converts an aryl aldehyde and a homoallylic alcohol to a 4-chlorotetrahydropyran in the presence of $InCl_3$.[1564] Homoallylic alcohols, protected as —O(CHMeOAc) react with BF_3•OEt_2 and acetic acid to give 4-acetoxytetrahydropyrans or with $SnBr_4$ to give 4-bromotetrahydropyrans.[1565] Homoallylic alcohols with a vinyl silane moiety react with $InCl_3$ and an aldehyde to give a dihydropyran.[1566]

A closely related reaction has been performed with activated aldehydes or ketones; without a catalyst (e.g., chloral and acetoacetic ester), but with heat.[1567] The product in these cases is a β-hydroxy alkene, and the mechanism is pericyclic:[1568]

This reaction is reversible and suitable β-hydroxy alkenes can be cleaved by heat (**17-32**). There is evidence that the cleavage reaction occurs by a cyclic mechanism (see **17-32**), and, by the principle of microscopic reversibility, the addition mechanism should be cyclic too.[1569] Note that this reaction is an oxygen analogue of the ene synthesis (**15-23**). This reaction can also be done with unactivated aldehydes[1570] and ketones[1571] if Lewis acid catalysts [e.g., dimethylaluminum chloride (Me_2AlCl) or ethylaluminum dichloride ($EtAlCl_2$)] are used.[1572] Lewis acid catalysts also increase rates with activated aldehydes.[1573] The use of optically active catalysts has given optically active products with a high % ee.[1574]

96

In a related reaction, alkenes can be added to aldehydes and ketones to give reduced alcohols (**96**). This has been accomplished by several methods,[1575] including treatment

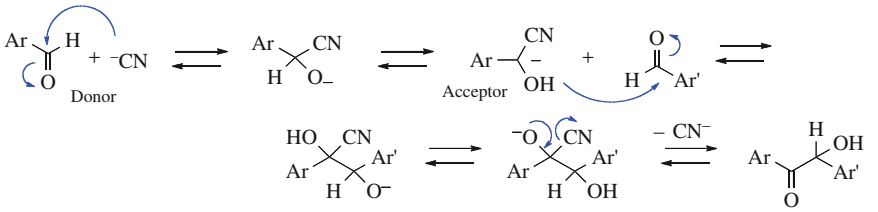
with SmI_2[1576] or Zn and Me_3SiCl,[1577] and by electrochemical[1578] and photochemical[1579] methods. Most of these methods have been used for intramolecular addition and most or all involve free radical intermediates.

There is an *aza-Prins reaction*, promoted by TiI_4 and I_2.[1580]

OS **IV**, 786. See also, OS **VII**, 102.

16-55 The Benzoin Condensation



Benzoin aldehyde condensation

97

When certain aldehydes are treated with cyanide ion, *benzoins* (**97**) are produced in a reaction called the *benzoin condensation*. The condensation can be regarded as involving the addition of one molecule of aldehyde to the C=O group of another. The reaction only occurs with aromatic aldehydes, but not all of them,[1581] and for glyoxals (RCOCHO). The two molecules of aldehyde obviously perform different functions. The one that no longer has a C—H bond in the product is called the *donor*, because it has "donated" its hydrogen to the oxygen of the other molecule, the *acceptor*. Some aldehydes can perform only one of these functions, and hence cannot be self-condensed, though they can often be condensed with a different aldehyde. For example, *p*-dimethylaminobenzaldehyde is not an acceptor, but only a donor. Thus it cannot condense with itself. It can condense with benzaldehyde, which can perform both functions, but is a better acceptor than it is a donor. *N*-alkyl-3-methylimidazolium salts catalyze the reaction,[1582] as does an imidazole-based solid supported catalyst.[1583]

The following is the accepted mechanism[1584] for this reversible reaction, which was originally proposed by Lapworth in 1903:[1585]

The key step, the loss of the aldehyde proton, can take place because the acidity of this C—H bond is increased by the electron-withdrawing power of the CN group. Thus, cyanide is a highly specific catalyst for this reaction, because, almost uniquely, it can perform three functions: (1) It acts as a nucleophile; (2) its electron-withdrawing ability permits loss of the aldehyde proton; and (3) having done this, it then acts as a leaving group. Certain thiazolium salts can also catalyze the reaction.[1586] In this case, aliphatic aldehydes can also be used[1587] (the products are called *acyloins*), and mixtures of aliphatic and aromatic aldehydes give mixed α-hydroxy ketones.[1588] The reaction has also been carried out without cyanide, by using the benzoylated cyanohydrin as one of the components in a phase-transfer catalyzed process. By this means, products can be obtained from aldehydes that normally fail to self-condense.[1589] The condensation has also been done with excellent enantioselectivity using benzoyl formate decarboxylase.[1590] Enantiopure triazolium salts have been evaluated as catalysts in the enantioselective benzoin condensation.[1591] *N*-Heterocyclic carbene catalysts have been used for asymmetric induction.[1592]

A "mixed"-benzoin condensation has been accomplished by using aryl silyl ketones [$ArC(=O)SiMe_2Ph$] and aldehydes with a La catalyst.[1593] The reaction of acylsilanes and aldehydes, catalyzed by metal cyanides, is known as the silyl-benzoin reaction.[1594]

OS **I**, 94; **VII**, 95.

16-56 Addition of Radicals to C=O, C=S, C=N Compounds

Radical cyclization is not limited to reaction with a C=C unit (see **15-29** and **15-30**), and reactions with both C=N and C=O moieties are known. Reaction of $MeON{=}CH(CH_2)_3CHO$ with Bu_3SnH and AIBN, for example, led to *trans*-2-(methoxyamino)cyclopentanol in good yield.[1595] Conjugated ketones add to aldehyde via the β carbon under radical conditions (2 molar equivalents of Bu_3SnH and 0.1 equiv of CuCl) to give a β-hydroxy ketone.[1596]

In a related reaction, diazo compounds add to ketenes to give allenes.[1597]

Addition of radical to the C=N unit of R–C=N–SPh[1598] or R–C=N–OBz[1599] led to cyclic imines. Radical addition to simple imines leads to aminocycloalkenes.[1600] Radicals

also add to the carbonyl unit of phenylthio esters to give cyclic ketones.[1601] Carbon-centered radicals add to imines.[1602] The reaction of an alkyl halide with BEt_3 in aq methanol, for example, gives the imine addition product, an alkylated amine.[1603]

Secondary alkyl iodides add to *O*-alkyl oximes in the presence of BEt_3 and AIBN. This methodology was used to convert MeO_2C-CH=NOBn to MeO_2C—CH(R)NOBn.[1604] Benzylic halides add to imines under photochemical conditions, and in the presence of 1-benzyl-1,4-dihydronicotinamide[1605] or with BEt_3 in aq methanol.[1606] Tertiary alkyl iodides add to oxime ethers using BF_3•OEt_2 in the presence of BEt_3/O_2.[1607] *O*-Trityl oximes of 5- and 6-iodoaldehydes undergo radical cyclization to give oximes[1608] (also see Reaction **15-30**). Enantioselective radical addition reactions to *N*-benzoyl hydrazones used chiral ammonium salts.[1609] The Mn mediated reaction of allyl iodides with chiral *N*-acylhydrazones leads to chiral hydrazine derivatives.[1610]

N,N-Dimethylaniline reacts with aldehydes under photochemical conditions to give acyl addition via the carbon atom of one of the methyl groups.[1611] The reaction of $PhNMe_2$ and benzaldehyde, for example, gave $PhN(Me)CH_2CH(OH)Ph$ upon photolysis.

16.B.ii. Acyl Substitution Reactions

A. O,N, and S Nucleophiles

16-57 Hydrolysis of Acyl Halides

Hydroxy-de-halogenation

$$RCOCl + H_2O \longrightarrow RCOOH$$

Acyl halides are so reactive that hydrolysis is easily carried out.[1612] In fact, most simple acyl halides must be stored under anhydrous conditions or they may react with water in the air. Consequently, water is usually a strong enough nucleophile for the reaction, but in unreactive systems hydroxide ion may be required. The reaction is seldom synthetically useful, because acyl halides are normally prepared from acids. The reactivity order is F < Cl < Br < I.[1613] If a carboxylic acid is used as the nucleophile, an exchange may take place (see Reaction **16-79**). The mechanism[1613] of hydrolysis can be either S_N1 or tetrahedral, the former occurring in highly polar solvents and in the absence of strong nucleophiles.[1614] There is also evidence for the S_N2 mechanism in some cases.[1615]

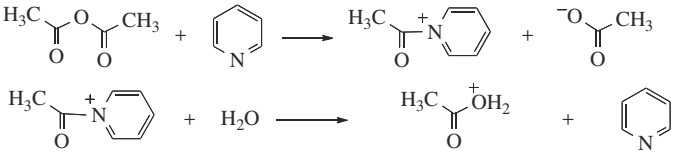
Hydrolysis of acyl halides is not usually catalyzed by acids, except for acyl fluorides, where hydrogen bonding can assist in the removal of F.[1616] There are several methods available for the hydrolysis of acyl fluorides.[1617]

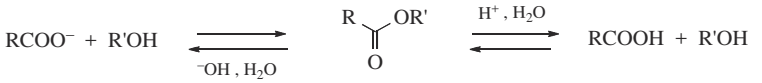


OS **II**, 74.

16-58 Hydrolysis of Anhydrides

Hydroxy-de-acyloxy-substitution

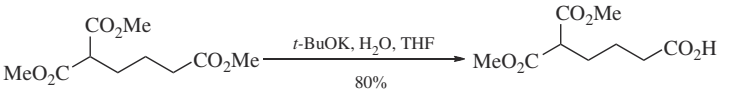
Anhydrides are somewhat more difficult to hydrolyze than acyl halides, but here too water is usually a strong enough nucleophile. The mechanism is usually tetrahedral.[1618] The S_N1 mechanism only occurs with acid catalysis and seldom even then.[1619] Anhydride hydrolysis can also be catalyzed by bases. Of course, hydroxide ion attacks more readily than water, but other bases can also catalyze the reaction. This phenomenon, called *nucleophilic catalysis* (Sec. 16.A.i, category 4), is actually the result of two successive tetrahedral mechanisms. For example, pyridine catalyzes the hydrolysis of acetic anhydride in this manner.[1620]



Many other nucleophiles similarly catalyze the reaction.

OS **I**, 408; **II**, 140, 368, 382; **IV**, 766; **V**, 8, 813.

16-59 Hydrolysis of Carboxylic Esters



Hydroxy-de-alkoxylation

Ester hydrolysis is usually catalyzed by acids or bases. Since OR is a much poorer leaving group than halide or OCOR, water alone does not hydrolyze most esters. When bases catalyze the reaction, the attacking species is the more powerful nucleophile $^-$OH. This reaction is called *saponification* and gives the salt of the acid. Acids catalyze the reaction by making the carbonyl carbon more positive, and therefore more susceptible to attack by the nucleophile. Both reactions are equilibrium reactions, so there must be a way to shift the equilibrium to the right for this to be useful. Since formation of the salt does just this, ester hydrolysis is almost always done for preparative purposes in basic solution,

unless the compound is base sensitive. Even in the case of **98**, however, selective base hydrolysis of the ethyl ester gave an 80% yield of the acid–dimethyl ester (**99**).[1621]

98 **99**

Ester hydrolysis can also be catalyzed[1622] by metal ions, by cyclodextrins,[1623] by enzymes,[1624] and by nucleophiles.[1621] Other reagents used to cleave carboxylic esters include Dowex-50,[1625] Me_3SiI,[1626] and $InCl_3$ on moist silica gel using microwave irradiation.[1627] Cleavage of phenolic esters is usually faster than carboxylic esters derived from aliphatic acids. The reagent Sm/I_2 at -78 °C has been used,[1628] ammonium acetate in aq methanol,[1629] Amberlyst 15 in methanol,[1630] and phenolic esters have been selectively hydrolyzed in the presence of alkyl esters on alumina with microwave irradiation.[1631] Allylic esters were cleaved with DMSO—I_2.[1632] Thiophenol with K_2CO_3 in NMP quantitatively converted methyl benzoate to benzoic acid.[1633] Allylic esters were cleaved with 2% Me_3SiOTf in dichloromethane,[1634] with $CeCl_3$•7 H_2O—NaI,[1635] and with $NaHSO_4$•silica gel.[1636] Lactones also undergo the reaction[1637] (but if the lactone is five- or six-membered, the hydroxy acid often spontaneously re-forms the lactone) and thiol esters (RCOSR′) give thiols R′SH. Typical reagents for this latter transformation include NaSMe in methanol,[1638] borohydride exchange resin–$Pd(OAc)_2$ for reductive cleavage of thiol esters to thiols,[1639] and $TiCl_4/Zn$ for the conversion of phenylthioacetates to thiophenols.[1640] Sterically hindered esters are hydrolyzed with difficulty (Sec. 10.G.i), but reaction of 2 equiv of *t*-BuOK with 1 equiv of water is effective.[1641] Hindered esters can also be cleaved by sequential treatment with zinc bromide and then water,[1642] with

silica gel in refluxing toluene,[1643] and on alumina when irradiated with microwaves.[1644] For esters insoluble in water the rate of two-phase ester saponification can be greatly increased by the application of ultrasound,[1645] and phase-transfer techniques have been applied.[1646]

Enzymatic hydrolysis of diesters with esterase has been shown to give the hydroxy-ester,[1647] and selective hydrolysis of dimethyl succinate to monomethyl succinic acid was accomplished with aq NaOH in THF.[1648] Hydrolysis of vinyl esters leads to ketones, and the reaction of *C*-substituted vinyl acetates with an esterase derived from *Marchantia polymorpha* gave substituted ketones with high enantioselectivity.[1649] Scandium triflate was shown to hydrolyze α-acetoxy ketones to α-hydroxy ketones.[1650]

Ingold[1651] has classified the acid- and base-catalyzed hydrolyses of esters (and the formation of esters, since these are reversible reactions and thus have the same mechanisms) into eight possible mechanisms (Table 16.3),[1651,1652] depending on the following criteria: (1) acid- or base catalyzed, (2) unimolecular or bimolecular, and (3) acyl cleavage or alkyl cleavage.[1653] All eight of these are S_N1, S_N2, or tetrahedral mechanisms. The acid-catalyzed mechanisms are shown with reversible arrows. They are not only reversible, but also symmetrical; that is, the mechanisms for ester formation are exactly the same as for hydrolysis, except that H replaces R. Internal proton transfers, such as shown for **B** and **C**, may not actually be direct but may take place through the solvent. There is much physical evidence to show that esters are initially protonated on the carbonyl and not on the alkyl oxygen (Chap 8, Ref. 17). Nevertheless the $A_{AC}1$ mechanism is shown as proceeding through the ether-protonated intermediate **A**, since it is difficult to envision OR′ as a leaving group here. It is of course possible for a reaction to proceed through an intermediate even if only a tiny concentration is present. The designations $A_{AC}1$, and so on, are those of Ingold. The $A_{AC}2$ and $A_{AC}1$ mechanisms are also called A2 and A1, respectively. Note that the $A_{AC}1$ mechanism is actually the same as the S_N1cA mechanism for this type of substrate and that $A_{AL}2$ is analogous to S_N2cA. Some authors use A1 and A2 to refer to all types of nucleophilic substitution in which the leaving group first acquires a proton. The base-catalyzed reactions are not shown with reversible arrows, since they are reversible only in theory and not in practice. Hydrolyses taking place under neutral conditions are classified as B mechanisms. Molecular dynamics has shown that "the rate of hydrolysis of methyl formate in pure water is consistent with mechanisms involving cooperative catalysis by autoionization-generated hydroxide and hydronium, a process known to have an activation free energy of 23.8 kcal mol^{-1} (99.6 kJ mol^{-1})."[1654]

[a]See Ref. 1652

Of the eight mechanisms, seven have actually been observed in the hydrolysis of carboxylic esters. The one that has not been observed is the $B_{AC}1$ mechanism.[1655] The most common mechanisms are the $B_{AC}2$ for basic catalysis and the $A_{AC}2$[1656] for acid catalysis, that is, the two tetrahedral mechanisms. Both involve acyl–oxygen cleavage. The evidence is (1) hydrolysis with $H_2{}^{18}O$ results in the ^{18}O appearing in the acid and not in the alcohol;[1657] (2) esters with chiral R′ groups give alcohols with *retention* of configuration;[1658] (3) allylic R′ gives no allylic rearrangement;[1659] (4) neopentyl R′ gives no rearrangement[1660]; all these facts indicate that the O—R′ bond is not broken. It has been concluded that two molecules of water are required in the $A_{AC}2$ mechanism, as shown:

If this were so, the protonated derivatives **B** and **C** would not appear at all. This conclusion stems from a value of *w* (see Sec. 8.C) of ~ 5, indicating that water acts as a proton donor here as well as a nucleophile.[1661] Termolecular processes are rare, but in this case the two water molecules are already connected by a hydrogen bond. (A similar mechanism, called $B_{AC}3$, also involving two molecules of water, has been found for esters that hydrolyze without a catalyst.[1662] Such esters are mostly those containing halogen atoms in the R group.)

The other mechanism involving acyl cleavage is the $A_{AC}1$ mechanism. This is rare, being found only where R is very bulky, so that bimolecular attack is sterically hindered, and only in ionizing solvents. The mechanism has been demonstrated for esters of 2,4,6-trimethylbenzoic acid (mesitoic acid). This acid depresses the freezing point of sulfuric acid four times as much as would be predicted from its molecular weight, which is evidence for the equilibrium

$$\mathrm{ArCOOH} + 2\mathrm{H_2SO_4} \rightleftharpoons \mathrm{Ar\overset{+}{C}O} + \mathrm{H_3O^+} + 2\mathrm{HSO_4^-}$$

In a comparable solution of benzoic acid, the freezing point is depressed only twice the predicted amount, indicating only a normal acid–base reaction. Further, a sulfuric acid solution of methyl mesitoate when poured into water gave mesitoic acid, while a similar solution of methyl benzoate similarly treated did not.[1663] The $A_{AC}1$ mechanism is also found when acetates of phenols or of primary alcohols are hydrolyzed in concentrated (>90%) H_2SO_4 (the mechanism under the more usual dilute acid conditions is the normal $A_{AC}2$).[1664]

The mechanisms involving alkyl–oxygen cleavage are ordinary S_N1 and S_N2 mechanisms in which OCOR (an acyloxy group) or its conjugate acid is the leaving group. Two of the three mechanisms, the $B_{AL}1$ and $A_{AL}1$ mechanisms, occur most readily when R′ comes off as a stable carbocation (i.e., when R′ is tertiary alkyl, allylic, benzylic, etc.). For acid

[1655] This is an S_N1 mechanism with OR' as leaving group, which does not happen.

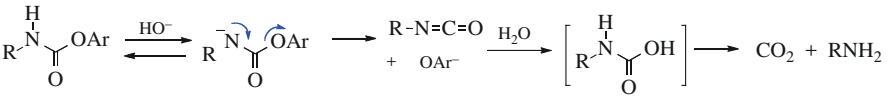
catalysis, most esters with this type of alkyl group (especially tertiary alkyl) cleave by this mechanism, but even for these substrates, the $B_{AL}1$ mechanism occurs only in neutral or weakly basic solution, where the rate of attack by hydroxide is so slowed that the normally slow (by comparison) unimolecular cleavage takes over. These two mechanisms have been established by kinetic studies, ^{18}O labeling, and isomerization of R′.[1665] Secondary and benzylic acetates hydrolyze by the $A_{AC}2$ mechanism in dilute H_2SO_4, but in concentrated acid the mechanism changes to $A_{AL}1$.[1665] Despite its designation, the $B_{AL}1$ mechanism is actually uncatalyzed (as is the unknown $B_{AC}1$ mechanism).

The two remaining mechanisms, $B_{AL}2$ and $A_{AL}2$, are very rare. The $B_{AL}2$ mechanism because it requires hydroxide ion to attack an alkyl carbon when an acyl carbon is also available,[1666] and the $A_{AL}2$ because it requires water to be a nucleophile in an S_N2 process. Both have been observed, however. The $B_{AL}2$ has been seen in the hydrolysis of β-lactones under neutral conditions[1667] (because cleavage of the C—O bond in the transition state opens the four-membered ring and relieves strain), the alkaline hydrolysis of methyl 2,4,6-tri-*tert*-butyl benzoate,[1668] and in the unusual reaction:[1669]

$$\mathrm{ArCOOMe} + \mathrm{RO^-} \longrightarrow \mathrm{ArCOO^-} + \mathrm{ROMe}$$



When it does occur, the $B_{AL}2$ mechanism is easy to detect, since it is the only one of the base-catalyzed mechanisms that requires inversion at R′. However, in the last example given, the mechanism is evident from the nature of the product, since the ether could have been formed in no other way. The $A_{AL}2$ mechanism has been reported in the acid cleavage of γ-lactones.[1670]

To sum up the acid-catalysis mechanisms, $A_{AC}2$ and $A_{AL}1$ are the common mechanisms, the latter for R′ that give stable carbocations, the former for practically all the rest. The $A_{AC}1$ mechanism is rare, being found mostly with strong acids and sterically hindered R. The $A_{AL}2$ mechanism is even rarer. For basic catalysis, $B_{AC}2$ is almost universal; $B_{AL}1$ occurs only with R′ that give stable carbocations and then only in weakly basic or neutral solutions; $B_{AL}2$ is very rare; and $B_{AC}1$ has never been observed.

The above results pertain to reactions in solution. In the gas phase,[1671] reactions can take a different course, as illustrated by the reaction of carboxylic esters with MeO^-, which in the gas phase was shown to take place only by the $B_{AL}2$ mechanism,[1672] even with aryl esters,[1673] where this means that an S_N2 mechanism takes place at an aryl substrate. However, when the gas-phase reaction of aryl esters was carried out with MeO^- ions, each of which was solvated with a single molecule of MeOH or H_2O, the $B_{AC}2$ mechanism was observed.[1672]

In the special case of alkaline hydrolysis of *N*-substituted aryl carbamates, there is another mechanism[1674] involving elimination–addition:[1675]

This mechanism does not apply to unsubstituted or *N,N*-disubstituted aryl carbamates, which hydrolyze by the normal mechanisms. Carboxylic esters substituted in the α position by an electron-withdrawing group (e.g., CN or CO_2Et) can also hydrolyze by a similar mechanism involving a ketene intermediate.[1676] These elimination–addition mechanisms usually are referred to as E1cB mechanisms, because that is the name given to the elimination portion of the mechanism (Sec. 17.A.iii).

The acid-catalyzed hydrolysis of enol esters ($RCOOCR'=CR$) can take place either by the normal $A_{AC}2$ mechanism or by a mechanism involving initial protonation on the double-bond carbon, similar to the mechanism for the hydrolysis of enol ethers given in Reaction **10-6**,[1677] depending on reaction conditions.[1678] In either case, the products are the carboxylic acid (RCO_2H) and the aldehyde or ketone ($R—CHCOR'$).

Ester hydrolyses with concomitant decarboxylation are listed at Reaction **12-40**.

16-60 Hydrolysis of Amides

Hydroxy-de-amination

Unsubstituted amides ($RCONH_2$) can be hydrolyzed with either acidic or basic catalysis, and the products are, respectively, the free acid and the ammonium ion or the salt of the acid and ammonia. *N*-Substituted ($RCONHR'$) and *N,N*-disubstituted ($RCONR_2'$) amides can be hydrolyzed analogously, and the product is the primary or secondary amine, respectively (or their salts), rather than ammonia. Twisting of the amide bond leads to an acceleration of water-promoted hydrolysis reactions.[1679] Lactams, imides, cyclic imides, hydrazides, and so on, also undergo the reaction.

Water alone is not sufficient to hydrolyze most amides,[1680] since NH_2 is even a poorer leaving group than OR.[1681] Prolonged heating is often required, even with acidic or basic catalysts.[1682] Treatment of primary amides with phthalic anhydride at 250 °C and 4 atm

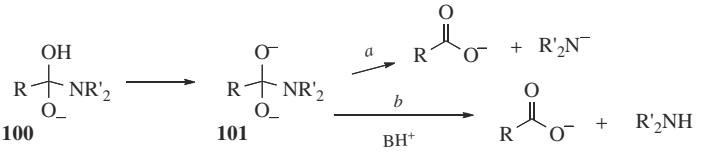
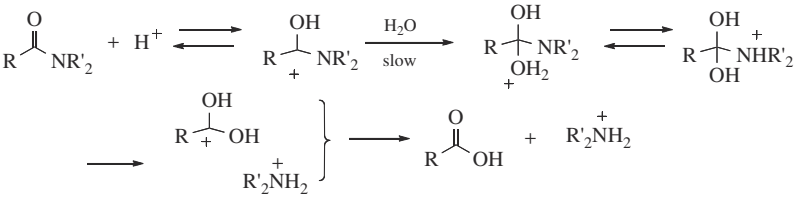
gives the carboxylic acid and phthalimide.[1683] Hydrolysis of carbamates ($RNHCO_2R$) to the corresponding amine can be categorized in this section. Although the product is an amine and the carboxyl unit fragments, this reaction is simply a variation of amide hydrolysis. Strong acids [e.g., trifluoroacetic acid (in dichloromethane)] are usually employed.[1684] Treatment of *N*-Boc derivatives ($RNHCO_2t$-Bu) with $AlCl_3$[1685] or with aq sodium *tert*-butoxide[1686] gave the amine. The byproducts of this reaction are typically carbon dioxide and isobutylene.

In difficult cases, nitrous acid, NOCl, N_2O_4,[1687] or a similar compound can be used (unsubstituted amides only[1688]). These reactions involve a diazonium ion (see Reaction **13-19**) and are much faster than ordinary hydrolysis. The benzamide–nitrous acid reaction took place 2.5×10^7 times faster than ordinary hydrolysis, for example.[1689] Another procedure for difficult cases involves treatment with aq sodium peroxide.[1690] In still another method, the amide is treated with water and *t*-BuOK at room temperature.[1691] A kinetic study has been done on the alkaline hydrolyses of *N*-trifluoroacetyl aniline derivatives.[1692] Amide hydrolysis can also be catalyzed by nucleophiles (see Sec. 16.A.i, category 4).



100



The same framework of eight possible mechanisms discussed for ester hydrolysis in Reaction **16-59** can also be applied to amide hydrolysis.[1693] Both the acid- and base-catalyzed hydrolyses are essentially irreversible, since salts are formed in both cases. For basic catalysis[1694] the mechanism is $B_{AC}2$. There is much evidence for this mechanism, similar to that discussed for ester hydrolysis. Molecular orbital studies on the mechanism of amide hydrolysis suggest a highly tetrahedral transition state.[1695] In certain cases, kinetic studies have shown that the reaction is second order in $^-$OH indicating that **100** can lose a proton to give **101**.[1696] Depending on the nature of R′, **101** can cleave directly to give the two negative ions (path *a*) or become N-protonated prior to or during the act of cleavage

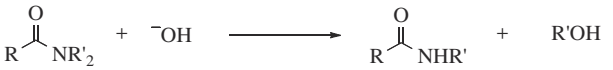
(path *b*), in which case the products are obtained directly and a final proton transfer is not necessary.[1697] Studies of the effect, on the rate of hydrolysis and on the ratio k_{-1}/k_2, of substituents on the aromatic rings in a series of amides ($CH_3CONHAr$) led to the conclusion that path *a* is taken when Ar contains

electron-withdrawing substituents and path *b* when electron-donating groups are present.[1698] The presence of electron-withdrawing groups helps stabilize the negative charge on the nitrogen, so that $NR_2'^-$ can be a leaving group (path *a*). Otherwise, the C—N bond does not cleave until the nitrogen is protonated (either prior to or in the act of cleavage), so that the leaving group, *even in the base-catalyzed reaction*, is not $NR_2'^-$ but the conjugate NHR_2' (path *b*). It is known that formation of **100** is the rate-determining step in the $B_{AC}2$ mechanism, but only at high-base concentrations. At lower concentrations of base, the cleavage of **100** or **101** becomes rate determining.[1699]



For acid catalysis, matters are less clear. The reaction is generally second order, and it is known that amides are primarily protonated on the oxygen. Because of these facts, it has been generally agreed that most acid-catalyzed amide hydrolysis takes place by the $A_{AC}2$ mechanism. Further evidence for this mechanism is that a small but detectable amount of ^{18}O exchange (see Sec. 16.A.i, category 3) has been found in the acid-catalyzed hydrolysis of benzamide[1700] (^{18}O exchange has also been detected for the base-catalyzed process,[1701] in accord with the $B_{AC}2$ mechanism). Kinetic data have shown that three molecules of water are involved in the rate-determining step,[1702] suggesting that, as in the $A_{AL}2$ mechanism for ester hydrolysis (Reaction **16-59**), additional water molecules take part in a process, such as:

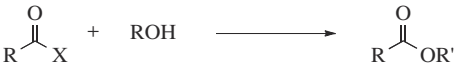
The four mechanisms involving alkyl–N cleavage (the AL mechanisms) do not apply to this reaction. They are not possible for unsubstituted amides, since the only N—C bond is the acyl bond. They are possible for *N*-substituted and *N,N*-disubstituted amides, but in these cases they give entirely different products and are not amide hydrolyses at all.

The reaction shown involves attack by the base on an *N*-alkyl group to give an alcohol. While rare, it has been observed for various *N-tert*-butylamides in 98% sulfuric acid, where the mechanism was $A_{AL}1$,[1703] and for certain amides containing an azo group, where a $B_{AL}1$ mechanism was postulated.[1704] Of the two first-order acyl cleavage mechanisms, only the $A_{AC}1$ has been observed, in concentrated sulfuric acid solutions.[1705] Of course, the diazotization of unsubstituted amides might be expected to follow this mechanism, and there is evidence that this is true.[1689]



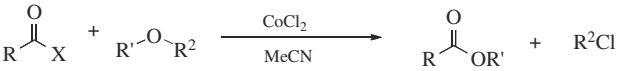
OS **I**, 14, 111, 194, 201, 286; **II**, 19, 25, 28, 49, 76, 208, 330, 374, 384, 457, 462, 491, 503, 519, 612; **III**, 66, 88, 154, 256, 410, 456, 586, 591, 661, 735, 768, 813; **IV**, 39, 42, 55, 58, 420, 441, 496, 664; **V**, 27, 96, 341, 471, 612, 627; **VI**, 56, 252, 507, 951, 967; **VII**, 4, 287; **VIII**, 26, 204, 241, 339, 451.

The oxidation of aldehydes to carboxylic acids can proceed by a nucleophilic mechanism, but more often it does not. The reaction is considered in Reaction **19-23**. Basic cleavage of β-keto esters and the haloform reaction could be considered at this point, but they are also electrophilic substitutions and are treated in Reactions **12-43** and **12-44**.

B. Attack by OR at an Acyl Carbon

16-61 Alcoholysis of Acyl Halides

Alkoxy-de-halogenation



The reaction between acyl halides and alcohols or phenols is the best general method for the preparation of carboxylic esters. It is believed to proceed by a S_N2 mechanism.[1706] As with Reaction **16-57**, however, the mechanism can be S_N1 or tetrahedral.[1613] Lewis acids (e.g., lithium perchlorate) can be used.[1707] The reaction is of wide scope, and many functional groups do not interfere. A base is frequently added to combine with the HX formed. When aq alkali is used, this is called the *Schotten–Baumann procedure*, but pyridine is also frequently used. Indeed, pyridine catalyzes the reaction by the nucleophilic catalysis route (see Reaction **16-58**). Both R and R′ may be primary, secondary, or tertiary alkyl or aryl. Enol esters can also be prepared by this method, though C-acylation competes in these cases. In difficult cases, especially with hindered acids or tertiary R′, the alkoxide can be used instead of the alcohol.[1708] Activated alumina has also been used as a catalyst,

[1703] Lacey, R.N. *J. Chem. Soc.* ***1960***, 1633; Druet, L.M.; Yates, K. *Can. J. Chem.* ***1984***, *62*, 2401.

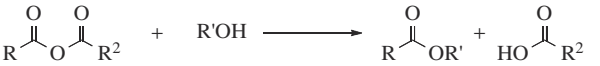
for tertiary R′.[1709] Thallium salts of phenols give very high yields of phenolic esters,[1710] and BiOCl is very effective for the preparation of phenolic acetates.[1711] Phase-transfer catalysis has been used for hindered phenols.[1712] Zinc has been used to couple alcohols and acyl chlorides,[1713] Zr compounds were used,[1714] and catalytic $Cu(acac)_2$ and benzoyl chloride was used to prepare the monobenzoate of ethylene glycol.[1715] Selective acylation is possible in some cases.[1716]

Acyl halides react with thiols, in the presence of Zn, to give the corresponding thio-ester.[1717] The reaction of acid chlorides or anhydrides (see **16-62**) with diphenyldiselenide, in the presence of $Sm/CoCl_2$[1718] or $Sm/CrCl_3$[1719] gave the corresponding seleno ester (PhSeCOMe).

Acyl halides can also be converted to carboxylic acids by using ethers instead of alcohols, as shown, in MeCN in the presence of certain catalysts [e.g., cobalt(II) chloride].[1720] A variation of this reaction has been reported that uses acetic anhydride (also see **16-62**).[1721]



This is a method for the cleavage of ethers (see also, Reaction **10-49**).

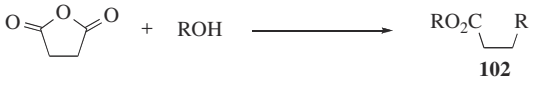
16-62 Alcoholysis of Anhydrides



Alkoxy-de-acyloxy-substitution

The scope of this reaction is similar to that of **16-61**. Anhydrides are somewhat less reactive than acyl halides, but they are often used to prepare carboxylic esters. Acids,[1722] Lewis acids,[1723] and bases (e.g., pyridine) are often used as catalysts.[1724] Acetic anhydride

and $NiCl_2$ with microwave irradiation converts benzylic alcohols to the corresponding acetate.[1725] The monoacetates of 1,2-diols have been prepared using $CeCl_3$ as a catalyst.[1726] Pyridine is a nucleophilic-type catalyst (see Reaction **16-58**), but DMAP is superior and can be used in cases where pyridine fails.[1727] Nonaromatic amidine derivatives have been used to catalyze the reaction with acetic anhydride.[1728] Formic anhydride is not a stable compound but esters of formic acid can be prepared by treating alcohols[1729] or phenols[1730] with acetic-formic anhydride. Cyclic anhydrides give monoesterified dicarboxylic acids (e.g., **102**).[1731] The asymmetric alcoholysis of cyclic anhydrides has been reviewed.[1732]

102

Alcohols can also be acylated by mixed organic–inorganic anhydrides [e.g., acetic-phosphoric anhydride, $MeCOOPO(OH)_2$,[1733] see Reaction **16-68**]. Thioesters of the type ArS(C=O)Me have been prepared by simple reaction of thiols and anhydrides in the presence of potassium carbonate,[1734] and from diphenyl disulfide and PBu_3, followed by treatment with acetic anhydride.[1735]

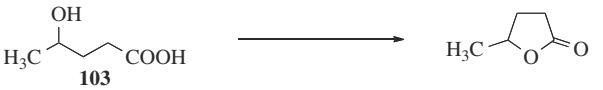
16-63 Esterification of Carboxylic Acids

Alkoxy-de-hydroxylation

$$RCOOH + R'OH \underset{}{\overset{H^+}{\rightleftharpoons}} RCOOR' + H_2O$$



The acid-catalyzed esterification of carboxylic acids with alcohols[1736] is the reverse of Reaction **16-60** and can be accomplished only if a means is available to drive the equilibrium to the right.[1737] There are many ways of doing this, among which are (1) addition of an excess of one of the reactants, usually the alcohol; (2) removal of the ester or the water by distillation; (3) removal of water by azeotropic distillation; and (4) removal of water by use of a dehydrating agent, silica gel,[1738] or a molecular sieve. When R′ is methyl, the most common way of driving the equilibrium is by adding excess MeOH; when R′ is

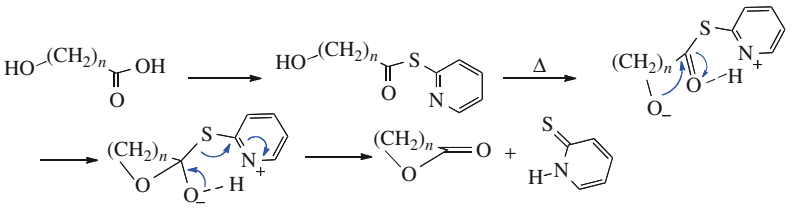
ethyl or larger, it is preferable to remove water by azeotropic distillation.[1739] The most common catalysts are H_2SO_4 and TsOH, but some reactive carboxylic acids (e.g., formic,[1740] trifluoroacetic[1741]) do not require a catalyst. Ammonium salts have been used to initiate esterification,[1742] and boric acid has been used to esterify α-hydroxy acids.[1743] The R′ group may be primary or secondary alkyl groups other than methyl or ethyl, but tertiary alcohols usually give carbocations and elimination. Phenols can sometimes be used to prepare phenolic esters, but yields are generally very low. Selective esterification of an aliphatic carboxylic acid in the presence of an aromatic acid was accomplished with $NaHSO_4$•SiO_2 and methanol.[1744] Diphenylammonium triflate was useful for direct esterification of carboxylic acids with longer chain aliphatic alcohols.[1745] Photoirradiation of carboxylic acid with CBr_4[1746] or CCl_4[1747] in methanol was shown to give the methyl ester, with high selectivity for nonconjugated acids in the case of CBr_4. Esterification has been accomplished in ionic liquids.[1748] A solid-state esterification was reported on P_2O_5/SiO_2.[1749] Diols are converted to the monoacetate by heating with acetic acid on a zeolite.[1750] Vinyl acetate and iodine has been used for the acetylation of alcohols.[1751]

O-Alkylisoureas react with conjugated carboxylic acids to give the corresponding ester with microwave irradiation,[1752] and a polymer-bound *O*-alkylurea has been used as well.[1753] Transition metal compounds of Ti,[1754] or Co[1755] catalyze esterification. Allylic sulfonium salts react with carboxylic acids to give allylic esters in the presence of CuBr.[1756] Triphenylphosphine dibromide is a useful esterification reagent.[1757] Phenols can be esterified using amide acetals.[1758]



The reaction of a carboxylic acid with an alcohol, in the presence of triphenylphosphine and DEAD gives the corresponding ester. This reaction is known as the *Mitsunobu reaction* (see **10-17**). A variation of this esterification reaction used azopyridines to mediate formation of the ester.[1759]

Both γ- and δ-hydroxy acids (e.g., **103**) are easily converted to a lactone by treatment with acids, or often simply on standing, but larger and smaller lactone rings cannot be made in this manner, because polyester formation occurs more readily.[1760] Often the conversion of one group to a hydroxyl group, gives the lactone directly, since the hydroxy acid cyclizes too rapidly for isolation. Such groups include keto or halogen that are γ or δ to a carbotyl group. β-Substituted β-hydroxy acids can be converted to β-lactones by treatment with benzenesulfonyl chloride in pyridine at 0–5 °C.[1761] ε-Lactones (seven-membered rings) have been made by cyclization of ε-hydroxy acids at high dilution.[1762] Macrocyclic lactones[1763] can be prepared indirectly in very good yields by conversion of the hydroxy acids to 2-pyridinethiol esters and adding these to refluxing xylene.[1764]

A closely related method, which often gives higher yields of a macrocyclic lactone, involves treatment of the hydroxy acids with 1-methyl- or 1-phenyl-2-halopyridinium salts, especially 1-methyl-2-chloropyridinium iodide (*Mukaiyama's reagent*).[1765] A macrocyclization technique has been developed based on formation of a mixed anhydride. The *Yamaguchi protocol*[1766] reacts a seco acid (the hydroxy acid precursor of a macrocyclic lactone) with 2,4,6-trichlorobenzoyl chloride. The resulting mixed anhydride is heated with DMAP in toluene.

Esterification is catalyzed by acids (not bases) in ways that were presented in Table 16.3 in Reaction **16-59**.[1653] The mechanisms are usually $A_{AC}2$, but $A_{AC}1$ and $A_{AL}1$ have also been observed.[1767] Certain acids (e.g., 2,6-di-ortho-substituted benzoic acids), cannot be esterified by the $A_{AC}2$ mechanism because of steric hindrance (Sec. 10.G.i, category 1). In such cases, esterification can be accomplished by dissolving the acid in 100% H_2SO_4 (forming the ion RCO^+) and pouring the solution into the alcohol ($A_{AC}1$ mechanism). The

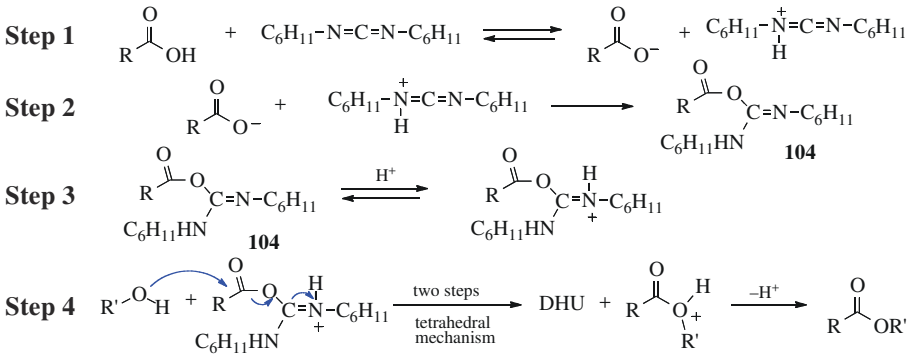
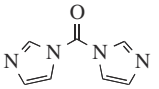
reluctance of hindered acids to undergo the normal $A_{AC}2$ mechanism can sometimes be put to advantage when, in a molecule containing two CO_2H groups, only the less hindered one is esterified. The $A_{AC}1$ pathway cannot be applied to unhindered carboxylic acids.

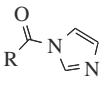


DCC

DHU



Another way to esterify a carboxylic acid is to treat it with an alcohol in the presence of a dehydrating agent.[1738] One of these is dicyclohexylcarbodiimide (DCC), which is converted in the process to dicyclohexylurea (DHU). The mechanism[1768] has much in common with the nucleophilic catalysis mechanism; the acid is converted to a compound with a better leaving group, but the conversion is not by a tetrahedral mechanism (as it is in nucleophilic catalysis), since the C—O bond remains intact during this step:



Evidence for this mechanism was the preparation of *O*-acylureas similar to **104** and the finding that when catalyzed by acids they react with alcohols to give esters.[1769] Hindered tertiary alcohols can be coupled via DCC to give the hindered ester.[1770] A polymer-bound carbodiimide has been used to prepare macrocyclic lactones.[1771] In at least one case, the reaction of $HOOCCH_2CN$ with DCC and *tert*-butanol gave the *tert*-butyl ester via a ketene intermediate.[1772]

There are limitations to the use of DCC; yields are variable and *N*-acylureas are side products. Many other dehydrating agents[1773] have been used, including DCC and an aminopyridine,[1774] chlorosilanes,[1775] and *N,N'*-carbonyldiimidazole (**105**).[1776] In the latter case, imidazolides (**106**) are intermediates that react with alcohols.

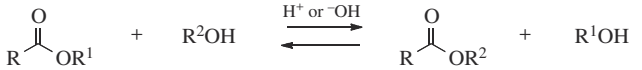
105

106

It is known that the Lewis acid BF_3 promotes the esterification by converting the acid to $RCO^{+-}BF_3^{-}OH$, so the reaction proceeds by an $A_{AC}1$ type of mechanism. The use of BF_3–etherate is simple and gives high yields.[1777] Other Lewis acids can be used.[1778]

Carboxylic esters can also be prepared by treating carboxylic acids with *tert*-butyl ethers and acid catalysts:[1779]

$$RCOOH + t\text{-}Bu{-}OR' \longrightarrow RCOOR' + H_2C{=}CMe_2 + H_2O$$



Carboxylic esters can be formed from the carboxylate anion and a suitable alkylating agent (Reaction **10-26**).

Thioesters of the type RSC(=S)R′ (a dithiocarboxylic ester) and RSC(C=O)R′ (a thiocarboxylic ester) can be generated by reaction of carboxylic acids with thiols. In one example, phosphorous pentasulfide was used in conjunction with a thiol to make dithiocarboxylic esters[1780] or thiocarboxylic esters.[1781] Thiocarboxylic esters were prepared from thiols and triflic acid.[1782]

16-64 Transesterification

Alkoxy-de-alkoxylation

Transesterification[1783] is catalyzed[1784] by acids[1785] or bases,[1786] or done under neutral conditions.[1787] It is an equilibrium reaction that must be shifted in the desired direction.[1788] In many cases, low-boiling esters can be converted to higher-boiling ones by the distillation of the lower-boiling alcohol as fast as it is formed. Reagents used to catalyze[1789]

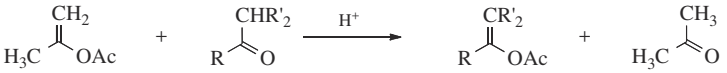
transesterification include various Lewis acids.[1790] Zwitterionic salts have been used as organocatalysts for this reaction.[1791] A polymer-bound siloxane has been used to induce transesterification.[1792] Vinyl acetate has been used for transesterification, usually with a coreagent or metal mediator.[1793] This reaction has been used as a method for the acylation of a primary OH in the presence of a secondary OH.[1794] Regioselectivity has also been accomplished by using enzymes (lipases) as catalysts.[1795] Lactones, (e.g., **107**) are easily opened by treatment with alcohols[1796] to give open-chain hydroxy esters.

107

Transesterification has been carried out with phase-transfer catalysts, without an added solvent.[1797] Nonionic superbases (see Sec. 8.A.i) of the type $P(RNCH_2CH_2)_3N$ catalyze the transesterification of carboxylic acid esters at 25 °C.[1798] Silyl esters ($R'CO_2SiR_3$) have been converted to alkyl esters ($R'CO_2R$) via reaction with alkyl halides and tetrabutylammonium fluoride.[1799] Thioesters are converted to phenolic esters by treatment with triphosgene–pyridine and then phenol.[1800]

Transesterification occurs by mechanisms[1801] that are identical with those of ester hydrolysis, except that ROH replaces HOH (by the acyl–oxygen fission mechanisms). When alkyl fission takes place, the products are the *acid* and the *ether*:



Therefore, transesterification reactions frequently fail when R′ is tertiary, since this type of substrate most often reacts by alkyl–oxygen cleavage. In such cases, the reaction is of the Williamson type with OCOR as the leaving group (see Reaction **10-10**).

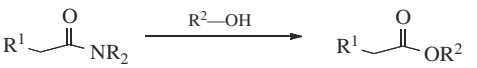
With enol esters (e.g., **108**), reaction with an alcohol gives an ester and the enol of a ketone, which readily tautomerizes to the ketone as shown. Hence, enol esters are good acylating agents for alcohols.[1802] This transformation has been accomplished in ionic liquid media,[1803] and there is a $PdCl_2/CuCl_2$ mediated version.[1804] Isopropenyl acetate can also be used to convert other ketones to the corresponding enol acetates in an exchange reaction:[1805]

Enol esters can also be prepared in the opposite type of exchange reaction, catalyzed by mercuric acetate[1806] or Pd(II) chloride,[1807] for example,



$$\mathrm{RCOOH + R'COOCH{=}CH_2 \underset{H_2SO_4}{\overset{Hg(OAc)_2}{\rightleftharpoons}} RCOOCH{=}CH_2 + R'COOH}$$

A closely related reaction is equilibration of a dicarboxylic acid and its diester to produce monoesters: The reaction of a carboxylic acid with ethyl acetate, in the presence of $NaHSO_4{\cdot}SiO_2$, was shown to give the corresponding ethyl ester.[1808] Iodine catalyzes the transesterification of β-keto esters.[1809]

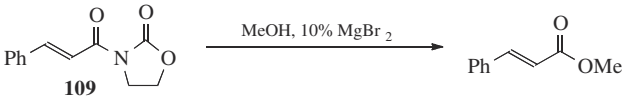
16-65 Alcoholysis of Amides



Alkoxy-de-amidation

Alcoholysis of amides is possible,[1810] although it is usually difficult. It has been most common with the imidazolide type of amides (e.g., **100**). For other amides, an activating agent is usually necessary before the alcohol will replace the NR_2 unit. *N*, *N*-Dimethylformamide, however, reacted with primary alcohols in the presence of 2,4,6-trichloro-1,3,5-pyrazine (cyanuric acid) to give the corresponding formate ester.[1811] Treatment of an amide with triflic anhydride ($CF_3SO_2OSO_2CF_3$) in the presence of pyridine, and then with an excess of alcohol, leads to the ester,[1812] as does treatment with $Me_2NCH(OMe)_2$ followed by

the alcohol.[1813] Trimethyloxonium tetrafluoroborate converted primary amides to methyl esters.[1814] The reaction of acetanilide derivatives with sodium nitrite in the presence of acetic anhydride–acetic acid leads to phenolic acetates.[1815] Acyl hydrazides ($RCONHNH_2$) were converted to esters by reaction with alcohols and various reagents,[1816] and methoxyamides (RCONHOMe) were converted to esters with $TiCl_4$/ROH.[1817] The reaction of an oxazolidinone amide (**109**) with methanol and 10% $MgBr_2$ gave the corresponding methyl ester.[1818]

C. Attack by OCOR at an Acyl Carbon

16-66 Acylation of Carboxylic Acids with Acyl Halides

Acyloxy-de-halogenation

$$RCOCl + R'COO^- \longrightarrow RCOOCOR'$$

Unsymmetrical, as well as symmetrical, anhydrides are often prepared by the treatment of an acyl halide with a carboxylic acid salt. If a metallic salt is used, Na^+, K^+, or Ag^+ are the most common cations, but more often pyridine or another tertiary amine is added to the free acid. The resulting salt is subsequently treated with the acyl halide. Zinc–DMF has been used to mediate the synthesis of symmetrical anhydrides from acid chlorides.[1819] Cobalt(II) chloride ($CoCl_2$) has been used as a catalyst.[1820] Mixed formic anhydrides are prepared from sodium formate and an aryl halide, by use of a solid-phase copolymer of pyridine-1-oxide.[1821] Symmetrical anhydrides can be prepared by reaction of the acyl halide with aq NaOH or $NaHCO_3$ under phase-transfer conditions,[1822] or with sodium bicarbonate with ultrasound.[1823]

Anhydrides can be formed from two molecules of an ordinary carboxylic acid only if a dehydrating agent is present so that the equilibrium can be driven to the right. Common dehydrating agents[1824] are acetic anhydride, trifluoroacetic anhydride, dicyclohexylcarbodiimide,[1825] and P_2O_5. Triphenylphosphine/CCl_3CN with triethylamine has also been used with benzoic acid derivatives.[1826] The method is very poor for the formation of mixed anhydrides, which in any case generally undergo disproportionation to the two simple anhydrides when they are heated. However, simple heating of dicarboxylic acids does give cyclic anhydrides, provided that the ring formed contains five, six, or seven members, for example:

Malonic acid and its derivatives, which would give four-membered cyclic anhydrides, do not give this reaction when heated, but undergo decarboxylation (**12-40**) instead.

Carboxylic acids exchange with amides and esters; these methods are sometimes used to prepare anhydrides if the equilibrium can be shifted. Enolic esters are especially good for this purpose, because the equilibrium is shifted by formation of the ketone.

The combination of KF with 2-acetoxypropene under microwave conditions was effective.[1827] Carboxylic acids also exchange with anhydrides; indeed, this is how acetic anhydride acts as a dehydrating agent in this reaction.

Anhydrides can be formed from certain carboxylic acid salts (e.g., by treatment of trimethylammonium carboxylates with phosgene):[1828]

or of thallium(I) carboxylates with thionyl chloride,[1710] or of sodium carboxylates with CCl_4 and a catalyst (e.g., CuCl or $FeCl_2$).[1829]

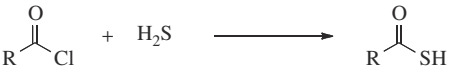
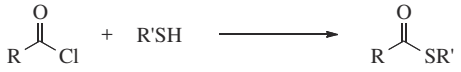
16-68 Preparation of Mixed Organic–Inorganic Anhydrides

Nitrooxy-de-acyloxy-substitution



$$(RCO)_2O + HONO_2 \longrightarrow RCOONO_2$$

Mixed organic–inorganic anhydrides are seldom isolated, although they are often intermediates when acylation is carried out with acid derivatives catalyzed by inorganic acids. Sulfuric, perchloric, phosphoric, and other acids form similar anhydrides, most of which are unstable or not easily obtained because the equilibrium lies in the wrong direction. These intermediates are formed from amides, carboxylic acids, and esters, as well as anhydrides. Organic anhydrides of phosphoric acid are more stable than most others and, for example, $RCOOPO(OH)_2$ can be prepared in the form of its salts.[1830] Mixed anhydrides of carboxylic and sulfonic acids ($RCOOSO_2R'$) are obtained in high yields by treatment of sulfonic acids with acyl halides or (less preferred) anhydrides.[1831]



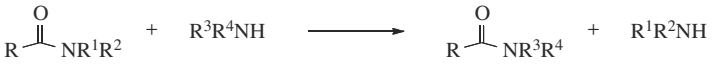
OS **I**, 495; **VI**, 207; **VII**, 81.

16-69 Attack by SH or SR at an Acyl Carbon[1832]

Mercapto-de-halogenation

Alkylthio-de-halogenation

Thiol acids and thiol esters[1833] can be prepared in this manner, which is analogous to Reaction **16-57** and **16-64**. Anhydrides[1834] and aryl esters ($RCOOAr$)[1835] are also used as substrates, but the reagents in these cases are usually HS^- and RS^-. Thiol esters can also be prepared by treatment of carboxylic acids with P_4S_{10}—Ph_3SbO,[1836] or with a thiol (RSH) and either polyphosphate ester or phenyl dichlorophosphate ($PhOPOCl_2$).[1837] Carboxylic acids are converted to thioacids with *Lawesson's reagent* (structure **18** in Reaction 16-**11**).[1838] Esters $RCOOR'$ can be converted to thiol esters ($RCOSR^2$) by treatment with trimethylsilyl sulfides (Me_3SiSR^2) and $AlCl_3$.[1839]



Alcohols, when treated with a thiol acid and zinc iodide, give thiol esters ($R'COSR$)[1840]

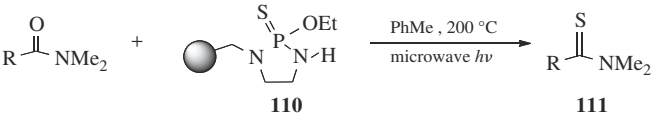
16-70 Transamidation



Alkylamino-de-amidation

It is sometimes necessary to replace one amide group with another, particularly when the group attached to nitrogen functions as a protecting group[1841] *N*-Benzyl amides can be converted to the corresponding *N*-allyl amide with allylamine and Ti catalysts.[1842] Reaction of *N*-Boc 2-phenylethylamine with Ti(O*i*Pr)$_4$ and benzyl alcohol, for example, gives the *N*-Cbz derivative.[1843] *N*-Carbamoyl amines were converted to *N*-acetyl amines with acetic anhydride, Bu_3SnH, and a Pd catalyst[1844] Triethylaluminum converts methyl carbamates ($ArNHCO_2Me$) to the corresponding propanamide.[1845]

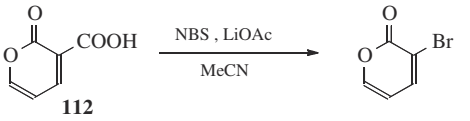
A related process reacts acetamide with amines and aluminum chloride to give the *N*-acetyl amine.[1846] Another related process converted imides to *O*-benzyloxy amides by the Sm catalyzed reaction with *O*-benzylhydroxylamine.[1847]

Thioamides can be prepared from amide by reaction with an appropriate sulfur reagent. The reaction of *N,N*-dimethylacetamide under microwave irradiation, with the polymer-bound reagent **110** (where ● = polymeric backbone) gave **111**.[1848] Reaction of the thioamide with $Bi(NO_3)_3 \cdot 5H_2O$ regenerates the amide.[1849] Other methods are known to convert a thioamide to an amide.[1850] Selenoamides [$RC(=Se)NR'_2$] have also been prepared from amides.[1851]

110 **111**

D. Attack by Halogen

16-71 The Conversion of Carboxylic Acids to Halides



Halo-de-oxido,oxo-tersubstitution

In certain cases, carboxyl groups can be replaced by halide. Acrylic acid derivatives ($ArCH{=}CHCOOH$), for example, react with 3 molar equivalents of Oxone in the presence of NaBr to give a vinyl bromide ($ArCH{=}CHBr$).[1852] Diphosphorus tetraiodide/tetraethylammonium bromide (TEAB) readily converts conjugated acids to vinyl

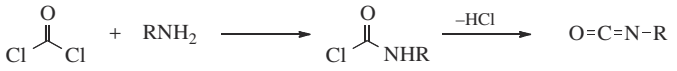
bromides.[1853] In other cases, conjugated acids, (e.g., **112**), have been converted to the bromide by reaction with (NBS, Reaction **14-3**) and LiOAc.[1854]

112

E. Attack by Nitrogen at an Acyl Carbon[1855]

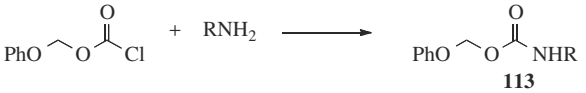
16-72 Acylation of Amines by Acyl Halides

Amino-de-halogenation



$$RCOX + NH_3 \longrightarrow RCONH_2 + HX$$

The treatment of acyl halides with ammonia or amines is a very general reaction for the preparation of amides.[1856] The reaction is exothermic and must be carefully controlled, usually by cooling or dilution. Ammonia gives unsubstituted amides, primary amines give *N*-substituted amides,[1857] and secondary amines give *N,N*-disubstituted amides. Arylamines can be similarly acylated. Hydroxamic acids have been prepared by this route.[1858] In some cases, aq alkali is added to combine with the liberated HCl. This is called the *Schotten–Baumann procedure*, as in Reaction **16-61**. Activated Zn can be used to increase the rate of amide formation when hindered amines and/or acid chlorides are used.[1859] A solvent-free reaction was reported using DABCO and methanol.[1860] Metal-mediated reactions using In,[1861] Sm,[1862] or a BiOCl mediated reaction[1863] have been reported. A variation of this basic reaction uses DMF with acyl halides to give *N,N*-dimethylamides.[1864] Formic acid and iodine react with amines to give the formamide.[1865]



Hydrazine and hydroxylamine also react with acyl halides to give, respectively, hydrazides ($RCONHNH_2$)[1866] and hydroxamic acids (RCONHOH).[1867] When phosgene is the acyl halide, both aliphatic and aromatic primary amines give chloroformamides

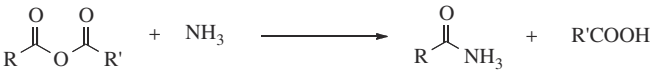
(ClCONHR) that lose HCl to give isocyanates (RNCO).[1868] This is one of the most common methods for the preparation of isocyanates.[1869] Similar

treatment with thiophosgene[1870] gives isothiocyanates. A safer substitute for phosgene in this reaction is trichloromethyl chloroformate (CCl_3OCOCl).[1871] When chloroformates (ROCOCl) are treated with primary amines, carbamates (ROCONHR′) are obtained.[1872] An example of this reaction is the use of benzyl chloroformate to protect the amino group of amino acids and peptides.

113



The $PhCH_2OCO$ group in **113** has been called the carbobenzoxy group,[1873] and is often abbreviated Cbz or Z, but it is really a benzyl carbamate. Another important group similarly used is Boc, which is a *tert*-butyl carbamate. In this case, the chloride ($Me_3COCOCl$) is unstable, so the anhydride [$(Me_3COCO)_2O$] is used instead, in an example of Reaction **16-73**. Amino groups in general are often protected by conversion to amides.[1874] The reactions proceed by the tetrahedral mechanism.[1875]

An interesting variation of this transformation reacts carbamoyl chlorides with organocuprates to give the corresponding amide.[1876]

This reaction, similar in scope and mechanism[1877] to Reaction **16-72**, can be carried out with ammonia or primary or secondary amines.[1878] Note that there is a report where a tertiary amine (an *N*-alkylpyrrolidine) reacted with acetic anhydride at 120 °C, in the presence of a BF_3•etherate catalyst, to give *N*-acetylpyrrolidine (an acylative dealkylation).[1879] Amino acids can be N-acylated using acetic anhydride and ultrasound.[1880] However, ammonia and primary amines can also give imides, in which two acyl groups are attached to the nitrogen. The conversion of cyclic anhydrides to cyclic imides is generally facile,[1881] although elevated temperatures are occasionally required to generate the imide.[1882] Microwave irradiation of formamide and a cyclic anhydride generates the cyclic imide.[1883] Cyclic imides have also been formed in ionic liquids.[1884] Cyclic imides were also formed by microwave irradiation of a polymer-bound phthalate after initial reaction with an amine.[1885]

The second step for imide formation, which is much slower than the first, is the attack of the amide nitrogen on the carboxylic carbon. Unsubstituted and *N*-substituted amides have been used instead of ammonia. Since the other product of this reaction is RCOOH, this is a way of "hydrolyzing" such amides in the absence of water.[1886]

Even though formic anhydride is not a stable compound (see Reaction **11-17**), amines can be formylated with the mixed anhydride of acetic and formic acids (HCOOCOMe)[1887] or with a mixture of formic acid and acetic anhydride. Acetamides are not formed with these reagents. Secondary amines can be acylated in the presence of a primary amine by conversion to their salts and addition of 18-crown-6.[1888] The crown ether complexes the primary ammonium salt, preventing its acylation, while the secondary ammonium salts, which do not fit easily into the cavity, are free to be acylated. Dimethyl carbonate can be used to prepare methyl carbamates in a related procedure.[1889] *N*-Acetylsulfonamides were prepared from acetic anhydride and a primary sulfonamide, catalyzed by Montmorillonite K10–FeO[1890] or sulfuric acid.[1891]

There are acylating reagents other than anhydrides of course. The reaction with acyl halides is discussed in Reaction **16-72**. There are a few specialized reagents. Kinetic resolution of racemic amines was accomplished using (1*S*,2*S*)-*N*-acetyl-1,2- bis(trifluoromethanesulfonamido)cyclohexane.[1892]

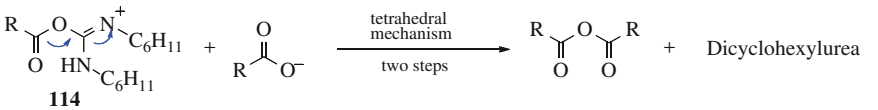
16-74 Acylation of Amines by Carboxylic Acids

Amino-de-hydroxylation

$$RCOOH + NH_3 \longrightarrow RCOO^-NH_4^+ \xrightarrow{\text{pyrolysis}} RCONH_2$$

When carboxylic acids are treated with ammonia or amines, salts are obtained. The salts of ammonia or primary or secondary amines can be pyrolyzed to give amides,[1893] but the method is less convenient than Reaction **16-72**, **16-73**, and **16-75** and is seldom of preparative value.[1894] Heating in the presence of a base (e.g., hexamethyldisilazide) makes the amide-forming process more efficient.[1895] Boronic acids catalyze the direct conversion of carboxylic acid and amine to amides.[1896] Polymer-bound reagents have also been used.[1897] Triphenylphosphine/-trichloroisocyanuric acid converts acids and amides to the amide.[1898] The *Burgess reagent* ($Et_3N^+{}^-SO_2N{-}CO_2Me$; see Reaction **17-29**) activates carboxylic acids for amide formation.[1899] The reaction of a carboxylic acid and imidazole under microwave irradiation gives the amide.[1900] Microwave irradiation of a secondary amine, formic acid, 2-chloro-4,6-dimethoxy [1,3,5]triazine, and a catalytic amount of DMAP leads to the formamide.[1901] Ammonium bicarbonate and formamide converts acids to amides with microwave irradiation.[1902] Formamides are produced from formic acid and anion nitriles in the presence of ZnO.[1903]



Lactams are readily produced from γ- or δ-amino acids,[1904] for example,

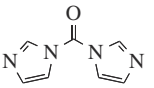
This lactonization process can be promoted by enzymes (e.g., pancreatic porcine lipase).[1905] Reduction of ω-azide carboxylic acids leads to macrocyclic lactams.[1906]

Although treatment of carboxylic acids with amines does not directly give amides, the reaction can be made to proceed in good yield at room temperature or slightly above by the use of coupling agents,[1907] the most important of which is dicyclohexylcarbodiimide. This reagent is very convenient and is used[1908] a great deal in peptide synthesis.[1909] A polymer-supported carbodiimide has been used.[1910] The mechanism is probably the same as in Reaction **16-63** up to the formation of **114**. This intermediate is then attacked by another molecule of $RCOO^-$ to give the anhydride $(RCO)_2O$, which is the actual species that reacts with the amine:



114

The anhydride has been isolated from the reaction mixture and then used to acylate an amine.[1911]

The synthetically important *Weinreb amides* [RCON(Me)OMe, see Reaction **16-82**] can be prepared from the carboxylic acid and MeO(Me)NH•HCl in the presence of tributylphosphine and 2-pyridine-*N*-oxide disulfide.[1912] Di(2-pyridyl)carbonate has been used in a related reaction that generates amides directly.[1913] Other promoting agents[1914] are $ArB(OH)_2$ reagents,[1915] *N,N'*-carbonyldiimidazole (**115**, in Reaction **16-63**),[1916] $POCl_3$,[1917] $TiCl_4$,[1918] molecular sieves,[1919] *Lawesson's reagent* (Reaction **16-11**),[1920] and $(MeO)_2POCl$.[1921] Certain dicarboxylic acids form amides simply on treatment with primary aromatic amines. In these cases, the cyclic anhydride is an intermediate and is the species actually attacked by the amine.[1922] Carboxylic acids can also be

converted to amides by heating with amides of carboxylic acids (exchange),[1923] sulfonic acids, or phosphoric acids, for example,[1924]

115

$$RCOOH + Ph_2PONH_2 \longrightarrow RCONH_2 + Ph_2POOH$$

or by treatment with trisalkylaminoboranes [$B(NHR')_3$], with trisdialkylaminoboranes [$B(NR_2')_3$],[1925]

$$RCOOH + B(NR_2')_3 \longrightarrow RCONR_2'$$

or with bis(diorganoamino)magnesium reagents [$(R_2N)_2Mg$].[1926] The reaction of thiocarboxylic acids and azides, in the presence of triphenylphosphine, gives the corresponding amide.[1927]

An important technique, discovered by R.B. Merrifield[1928] and since used for the synthesis of many peptides,[1929] is called *solid-phase synthesis* or *polymer-supported synthesis*.[1930] The reactions used are the same as in ordinary synthesis, but one of the reactants is anchored onto a solid polymer. For example, if it is desired to couple two amino acids (to form a dipeptide), the polymer selected might be polystyrene with CH_2Cl side chains. One of the amino acids, protected by (Boc), would then be coupled to the side chains. It is not necessary that all the side chains be converted, but a random selection will be converted. The Boc group is then removed by hydrolysis with trifluoroacetic acid in CH_2Cl_2 and the second amino acid is coupled to the first, using DCC or some other coupling agent. The second Boc group is removed, resulting in a dipeptide that is still anchored to the polymer. If this dipeptide is the desired product, it can be cleaved from the

polymer by various methods,[1931] one of which is treatment with HF. If a longer peptide is wanted, additional amino acids can be added by repeating the requisite steps.

The basic advantage of the polymer support techniques is that the polymer (including all chains attached to it) is easily separated from all other reagents, because it is insoluble in the solvents used. Excess reagents, other reaction products (e.g., dicyclohexylurea), side products, and the solvents themselves are quickly washed away. Purification of the polymeric species is rapid and complete. The process can even be automated,[1932] to the extent that six or more amino acids can be added to a peptide chain in one day. Commercial automated peptide synthesizers are now available.[1933]

Although the solid-phase technique was first developed for the synthesis of peptide chains and has seen considerable use for this purpose, it has also been used to synthesize chains of polysaccharides and polynucleotides; in the latter case, solid-phase synthesis has almost completely replaced synthesis in solution.[1934] The technique has been applied less often to reactions in which only two molecules are brought together (nonrepetitive syntheses), but many examples have been reported.[1935] Combinatorial chemistry in some ways can be viewed as an extension of the *Merrifield synthesis*, particularly when applied to peptide synthesis, and continues as an important part of modern organic chemistry.[1936]

16-75 Acylation of Amines by Carboxylic Esters

Amino-de-alkoxylation

$$\mathrm{RCOOR' + NH_3 \longrightarrow RCONH_2 + R'OH}$$

The conversion of carboxylic esters to amides is a useful reaction, and unsubstituted, *N*-substituted, and *N,N*-disubstituted amides can be prepared this way from the appropriate amine[1937] or ammonia.[1938] Both R and R′ can be alkyl or aryl, but *an especially good leaving group is p-nitrophenyl*. Ethyl trifluoroacetate was found to react selectively with primary amines to form the corresponding trifluoroacetyl amide.[1939] Many simple esters

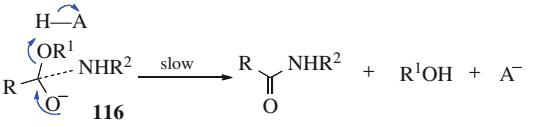
(R = Me, Et, etc.) are not very reactive, and strongly basic catalysis has been used in such cases,[1940] but catalysis by cyanide ion[1941] $MgBr_2$,[1942] InI_3,[1943] and acceleration by high pressure[1944] have been reported. Methyl esters[1945] and ethyl esters[1946] have been converted to the corresponding amide under microwave irradiation. Lithium amides have been used to convert esters to amides as well.[1947] β-Keto esters undergo the reaction especially easily.[1948] Aniline was treated with *n*-butyllithium to form the lithium amide, which reacted with an ester to give the amide.[1949] An enzyme-mediated amidation is known using amino cyclase I.[1950] The reaction of dimethyl carbonate and an amine is an effective way to prepare methyl carbamates.[1951]

Lactones give lactams when treated with ammonia or primary amines. Lactams are also produced from γ- and δ-amino esters in an internal example of this reaction. Lactonization has been accomplished in ionic liquids.[1952]

As in Reaction **16-72**, hydrazides and hydroxamic acids can be prepared from carboxylic esters, with hydrazine and hydroxylamine,[1953] respectively. Both hydrazine and hydroxylamine react more rapidly than ammonia or primary amines (the alpha effect, Sec. 10.G.ii). Imidates [RC(=NH)OR′] give amidines [$RC(=NH)NH_2$]. Isopropenyl formate is a useful compound for the formylation of primary and secondary amines.[1954]

$$R_2NH + HCOOCMe{=}CH_2 \longrightarrow R_2NCHO + CH_2{=}CMeOH \rightleftharpoons MeCOMe$$



Although more studies have been devoted to the mechanism of the acylation of amines with carboxylic esters than with other reagents, the mechanistic details are not yet entirely clear.[1955] In its broad outlines, the mechanism appears to be essentially $B_{AC}2$.[1956] Under normal basic conditions, the reaction is general base catalyzed,[1957] indicating that a proton is being transferred in the rate-determining step and that two molecules

of amine are involved.[1958] Alternatively, another base (e.g., H_2O or OH^-) can substitute for the second molecule of amine. With some substrates and under some conditions, especially at low pH, the breakdown of **116** can become rate determining.[1959] The reaction also takes place under acidic conditions and is general acid catalyzed, so that breakdown of **116** is rate determining and proceeds as follows:[1960]

116

Here HA may be $R^2NH_3^+$ or another acid. Intermediate **116** may or may not be further protonated on the nitrogen. Even under basic conditions, a proton donor may be necessary to assist leaving-group removal. Evidence for this is that the rate is lower with NR_2^- in liquid ammonia than with NHR_2 in water, apparently owing to the lack of acids to protonate the leaving oxygen.[1961]

In the special case of β-lactones, where small-angle strain is an important factor, alkyl–oxygen cleavage is observed ($B_{AL}2$ mechanism, as in the similar case of hydrolysis of β-lactones, Reaction **16-59**), and the product is not an amide but a β-amino acid (β-alanine).

β-Alanine

A similar result has been found for certain sterically hindered esters.[1962] This reaction is similar to **10-31**, with OCOR as the leaving group. Other lactones have been opened to ω-hydroxy amides with Dibal-H:$BnNH_2$.[1963]

This is an exchange reaction and is usually carried out with the salt of the amine.[1964] The leaving group is usually NH_2 rather than NHR or NR_2 and primary amines (in the form of their salts) are the most common reagents. Boron trifluoride can be added to complex with the leaving ammonia. Neutral amines also react in some cases to give the new amide.[1965] The reaction is catalyzed by Al(III).[1966] The reaction is often used to convert urea to substituted ureas: $NH_2CONH_2 + RNH_3^+ \rightarrow NH_2CONHR + NH_4^+$.[1967] An *N*-aryl group of a urea can be converted to a *N,N*-dialkyl group by heating the urea with the amine in an autoclave.[1968] *N*-alkyl substituted amides (alkyl = R) are converted to *N*-R′-substituted amides, where alkyl = R′, by treatment with N_2O_4 to give an *N*-nitroso compound, followed by treatment of this with a primary amine ($R'NH_2$).[1969] Lactams can be converted to ring-expanded lactams (e.g., **117**) if a side chain containing an amino group is present on the nitrogen. A strong base is used to convert the NH_2 to NH^-, which then acts as a nucleophile, expanding the ring by means of a transamidation.[1970] The discoverers call it the *Zip reaction*, by analogy with the action of zippers.[1971]

117

Lactams can be opened to ω-amino amides by reaction with amines at 10 kbar.[1972]

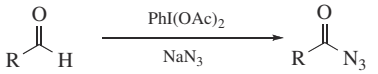
prepare amides and related compounds. The reaction of a primary amine, an alkyl halide with CO_2, in the presence of Cs_2CO_3/Bu_4NI, gave the corresponding carbamate.[1976]

OS **III**, 394; **IV**, 6, 569; **V**, 160, 166; **VI**, 1004.

Imides can be prepared by the attack of amides or their salts on acyl halides, anhydrides, and carboxylic acids or esters.[1977] A good synthetic method for the preparation of acyclic imides is the reaction between an amide and an anhydride at 100 °C catalyzed by H_2SO_4.[1978] When acyl chlorides are treated with amides in a 2: 1 molar ratio at low temperatures in the presence of pyridine, the products are *N,N*-diacylamides $[(RCO)_3N]$.[1979]

This reaction is often used to prepare urea derivatives, an important example being the preparation of barbituric acid (**118**).[1980]



118

When the substrate is oxalyl chloride (ClCOCOCl) and the reagent an unsubstituted amide, an acyl isocyanate (RCONCO) is formed. The "normal" product (RCONHCOCOCl) does not form, or if it does, it rapidly loses CO and HCl.[1981]

The same inorganic acid halides that convert alcohols to alkyl halides (Reaction **10-48**) also convert carboxylic acids to acyl halides.[1984] The reaction is the best and the most common method for the preparation of acyl chlorides. Bromides and iodides[1985] are also made in this manner, but much less often. Acyl bromides can be prepared with BBr_3 on alumina,[1986] or with ethyl tribromoacetae/PPh_3.[1987] Thionyl chloride[1988] is a good reagent, since the byproducts are gases and the acyl halide is easily isolated, but PX_3 and PX_5 (X = Cl or Br) are also commonly used.[1989] Hydrogen halides do not give the reaction. A particularly mild procedure, similar to one mentioned in Reaction **10-48**, involves reaction of the acid with Ph_3P in CCl_4, whereupon acyl chlorides are produced without obtaining any acidic compound as a byproduct.[1990]

Oxalyl chloride (**113**) and oxalyl bromide are mild and often superior reagents, since the oxalic acid byproduct decomposes to CO and CO_2, and the equilibrium is thus driven to the side of the other acyl halide.[1991] These reagents are commonly the reagent of choice, particularly when sensitive functionality is present elsewhere in the molecule.

119

Acyl fluorides can be prepared by treatment of carboxylic acids with cyanuric fluoride.[1992] *C*, *N*-Chelated di-*n*-butyltin(IV) fluoride has been used to prepare acyl fluorides.[1993] Acid salts are also sometimes used as substrates and acyl halides are used as reagents in an exchange reaction:

$$RCOOH + R'COCl \rightleftharpoons RCOCl + R'COOH$$

which probably involves an anhydride intermediate. This is an equilibrium reaction that must be driven to the desired side.

These reactions are most important for the preparation of acyl fluorides.[1994] Acyl chlorides and anhydrides can be converted to acyl fluorides by treatment with polyhydrogen fluoride–pyridine solution[1995] or with liquid HF at –10 °C.[1996] Formyl fluoride, which is a stable compound, was prepared by the latter procedure from the mixed anhydride of formic and acetic acids.[1997] Acyl fluorides can also be obtained by reaction of acyl chlorides with KF in acetic acid[1998] or with diethylaminosulfur trifluoride (DAST).[1999] Carboxylic esters and anhydrides can be converted to acyl halides other than fluorides by the inorganic acid halides mentioned in Reaction **16-79**, as well as with Ph_3PX_2 (X = Cl or Br),[2000] but this is seldom done. Halide exchange can be carried out in a similar manner. When halide exchange is done, it is always acyl bromides and iodides that are made from chlorides, since chlorides are by far the most readily available.[2001]

G. Attack by Carbon at an Acyl Carbon[2002]

16-81 The Conversion of Acyl Halides to Ketones with Organometallic Compounds[2003]

Alkyl-de-halogenation

Acyl halides react cleanly and under mild conditions with lithium dialkylcopper reagents (see Reaction **10-58**)[2004] to give high yields of ketones.[2005] The R′ group may be primary, secondary, or tertiary alkyl or aryl and may contain iodo, keto, ester, nitro, or cyano groups. The R groups that have been used successfully are methyl, primary alkyl, and vinylic. Secondary and tertiary alkyl groups can be introduced by the use of PhS(R)CuLi (Reaction **10-58**) instead of R_2CuLi,[2006] or by the use of either the mixed homocuprate $[(R'SO_2CH_2CuR)^- \ Li^+]$,[2007] or a magnesium dialkylcopper reagent '(RMeCuMgX).'[2008] Secondary alkyl groups can also be introduced with the copper–zinc

reagents [RCu(CN)ZnI].[2009] The R group may be alkynyl if a cuprous acetylide ($R^2C{\equiv}CCu$) is the reagent.[2010] Organocopper reagents generated *in situ* from highly reactive copper, and containing such functional groups as cyano, chloro, and ester, react with acyl halides to give ketones.[2011]

When the organometallic compound is a *Grignard reagent*,[2012] ketones are generally not obtained because the initially formed ketone reacts with a second molecule of RMgX to give the salt of a tertiary alcohol (Reaction **16-82**). Ketones *have* been prepared in this manner by the use of low temperatures, inverse addition (i.e., addition of the *Grignard reagent* to the acyl halide rather than the other way), excess acyl halide, and so on, but the yields are usually low, although high yields have been reported in THF at –78 °C.[2013] Pretreatment with a trialkylphosphine followed by the *Grignard reagent* gave the ketone.[2014] Using CuBr[2015] or a Ni catalyst[2016] with the *Grignard reagent* can lead to the ketone. Some ketones are unreactive toward *Grignard reagents* for steric or other reasons; these can be prepared in this way.[2017] Other methods involve running the reaction in the presence of Me_3SiCl[2018], which reacts with the initial adduct in the tetrahedral mechanism (Sec. 16.A.i), and the use of a combined *Grignard*–$LiNEt_2$ reagent.[2019] Certain metallic halides, notably ferric and cuprous halides, are catalysts that improve the yields of ketone at the expense of tertiary alcohol.[2020] For this catalysis, both free radical and ionic mechanisms have been proposed.[2021]

Grignard reagents react with ethyl chloroformate to give carboxylic esters [EtOCOCl + RMgX → EtOCOR].

The Pd catalyzed reaction of an acyl chloride and an arylboronic acid[2022] or an alkenylboronic acid[2023] gives a ketone. Surfactants are known to promote arylboronic acid coupling reactions.[2024] Arylboronic esters add to carbamoyl halides, in the presence of a Pd catalyst, to give the corresponding benzamide.[2025] Arylboronic acids also react with

anhydrides to give a ketone in the presence of a Pd catalyst.[2026] Similar reaction of acid chlorides, $NaBPh_4$, KF, and a Pd catalyst gave the aryl ketone.[2027]

Other organometallic reagents[2028] give good yields of ketones when treated with acyl halides because, as with R_2CuLi or R_2Cd, these compounds do not generally react with the ketone product. A particularly useful class of organometallic reagent are the organocadmium reagents (R_2Cd), prepared from *Grignard reagents* (Reaction **12-22**). In this case, R may be an aryl or primary alkyl. In general, secondary and tertiary alkylcadmium reagents are not stable enough to be useful in this reaction.[2029] An ester group may be present in either $R'COX$ or R_2Cd. Direct treatment of the acid chloride with an alkyl halide and Cd metal leads to the ketone in some cases.[2030] Organozinc compounds behave similarly to dialkylcadmium reagents, but are used less often.[2031] Organotin reagents (R_4Sn) react with acyl halides to give high yields of ketones, if a Pd complex is present.[2032] Organolead reagents (R_4Pb) behave similarly.[2033] Allylic halides and In metal react with acyl chlorides to give the ketone.[2034] Various other groups (e.g., nitrile, ester, and aldehyde) can be present in the acyl halide without interference. Other reagents include organomanganese compounds[2035] (R can be primary, secondary, or tertiary alkyl, vinylic, alkynyl, or aryl), organozinc,[2036] organobismuth,[2037] and organothallium compounds (R can be primary alkyl or aryl).[2038] The reaction of an α-halo-ketone and an acyl chloride with SmI_2 leads to a β-diketone.[2039]

Antimony alkynes (e.g., $Ph_2Sb—C{\equiv}C—Ph$) react with acid chloride in the presence of a Pd catalyst to give the conjugated alkynyl ketone.[2040] Such conjugated ketones can also be prepared from an acyl halide, a terminal alkyne, and a CuI,[2041] Pd,[2042] or Fe catalyst,[2043]

or with In metal.[2044] Terminal alkynes react with chloroformates and a Pd catalyst to give the corresponding propargyl ester.[2045] Similar reaction of an alkyne with an acid chloride and a Pd—Cu[2046] or CuI catalyst,[2047] both with microwave irradiation, gave alkynyl ketones.

Acyl halides can also be converted to ketones by treatment with $Na_2Fe(CO)_4$ followed by R′X (Reaction **10-76**).

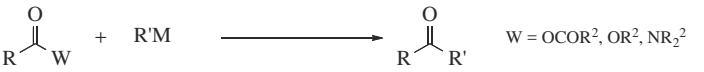
16-82 The Conversion of Anhydrides, Carboxylic Esters, or Amides to Ketones with Organometallic Compounds[2048]

Dialkyl,hydroxy-de-alkoxy,oxo-tersubstitution; Alkyl-de-acyloxy- or de-amido substitution



When carboxylic esters are treated with *Grignard reagents*, addition to the carbonyl (Reaction **16-24**) generates a ketone. Under the reaction conditions, the initially formed ketone usually undergoes acyl substitution of R^2 for OR′ (Reaction **16-81**), so that tertiary alcohols are formed in which two R groups are the same. Isolation of the ketone as the major product is possible in some cases, particularly when the reaction is done at low temperature[2049] and when there is steric hindrance to the carbonyl in the first-formed ketone. Esters (RCO_2Me) react with $Zn(BH_4)_2$/EtMgBr to give an alcohol [RCH(OH)Et].[2050] Formates give secondary alcohols and carbonates give tertiary alcohols in which all three R groups are the same: $(EtO)_2C{=}O + RMgX \rightarrow R_3COMgX$. Acyl halides and anhydrides behave similarly, though these substrates are employed less often.[2051] Many side reactions are possible, especially when the acid derivative or the *Grignard reagent* is branched: enolizations, reductions (not for esters, but for halides), condensations, and cleavages, but the most important is simple substitution (**16-81**), which in some cases can be made to predominate. When 1,4-dimagnesium compounds are used, carboxylic esters are converted to cyclopentanols.[2052] 1,5-Dimagnesium compounds give cyclohexanols, but in lower yields.[2053]

As is the case with acyl halides (Reaction **16-81**), anhydrides and carboxylic esters give tertiary alcohols (Reaction **16-82**) when treated with *Grignard reagents*. Low temperatures,[2054] the solvent HMPA,[2055] and inverse addition have been used to increase the yields of ketone.[2056] Amides give better yields of ketone at room temperature, but still not very high.[2057] Anhydrides can react with arylmagnesium halides at low temperature, and in the presence of (−)-sparteine, to give a keto acid with good enantioselectivity.[2058] Organocadmium reagents are less successful with these substrates than with acyl halides (Reaction **16-81**). Esters of formic acid, dialkylformamides, and lithium or sodium formate[2059] give good yields of aldehydes, when treated with *Grignard reagents*.

Organolithium compounds have been used to give ketones from carboxylic esters. The reaction must be carried out in a high-boiling solvent (e.g., toluene), since reaction at lower temperatures gives tertiary alcohols.[2060] Organolithium reagents also give good yields of carbonyl compounds with *N,N*-disubstituted amides.[2061] Dialkylformamides react to give aldehydes, other disubstituted amides give ketones and other acid derivatives have been used.[2062]

Ketones can also be obtained by treatment of the lithium salt of a carboxylic acid with an organolithium reagent (Reaction **16-28**). For an indirect way to convert carboxylic esters to ketones, see Reaction **16-82**. A similar reaction with hindered aryl carboxylic acids has been reported.[2063] Carboxylic acids can be treated with 2-chloro-4,6-dimethoxy[1,3,5] triazine and the RMgX/CuI to give ketones.[2064]

Disubstituted formamides can give addition of 2 molar equivalents of *Grignard reagent*. The products of this reaction (called *Bouveault reaction*) are an aldehyde and a tertiary amine.[2065] The use of an amide other than a formamide can give a ketone instead of an aldehyde, but yields are generally low. The addition of 2 molar equivalents of

phenyllithium to a carbamate gave good yields of the ketone, however.[2066] The reaction of *N*-(3-bromopropyl) lactams with *tert*-butyllithium gave cyclization to the bicyclic amino alcohol, and subsequent reduction with $LiAlH_4$ (Reaction **19-64**) gave the bicyclic amine.[2067] Ketones can also be prepared by treatment of thioamides with organolithium compounds (alkyl or aryl).[2068] Cerium reagents (e.g., $MeCeCl_2$) also add two R groups to an amide.[2069] More commonly, an organolithium reagent is treated with $CeCl_3$ to generate the organocerium reagent *in situ*.[2070] It has proven possible to add two different R groups by sequential addition of two *Grignard reagents*.[2071] Diketones have also been produced by using the bis(imidazole) derivative of oxalic acid.[2072] When an amide having a *gem*-dibromocyclopropyl unit elsewhere in the molecule was treated with methyllithium, Li—Br exchange was accompanied by intramolecular acyl addition to the amide carbonyl, giving a bicyclic amino alcohol.[2073]

121 **122**

N-Methoxy-*N*-methyl amides, (e.g., **120**) are referred to as a *Weinreb amide*.[2074] When a *Weinreb amide* reacts with a *Grignard reagent* or an organolithium reagent,[2075] the product is the ketone. The reaction of **121** (TBDPSO = tertiarybutyldiphenylsilyl) with 3-butenylmagnesium bromide to give ketone **122** is a typical example.[2076] Aryloxy carbamates with a *Weinreb amide* unit [ArO_2C-NMe(OMe)] react with RMgBr and then R′Li to give an unsymmetrical ketone [RC(=O)R′].[2077] Intramolecular displacement of a *Weinreb amide* by an organolithium reagent generated *in situ* from an iodide precursor leads to cyclic ketones.[2078] Reaction with vinylmagnesium bromide led to a β-*N*-methoxy-*N*-methylamino ketone, presumably by initial formation of the conjugated ketone followed by *Michael addition* (Reaction **15-24**) of the liberated amine.[2079] By the use of the compound *N*-methoxy-*N,N',N'*-trimethylurea, it is possible to add two R groups as RLi, the same or different, to a CO group.[2080] Another variant used organocerium reagents with (*Z*)-α,β-unsaturated *Weinreb amides* to give (*Z*)-α,β-unsaturated ketones.[2081]

N,N-Disubstituted amides can be converted to alkynyl ketones by treatment with alkynylboranes: $RCONR_2^2 + (R'C{\equiv}C)_3B \rightarrow RCOC{\equiv}CR'$.[2082] Lactams react with triallylborane to give cyclic 2,2-diallyl amines after treatment with methanol and then aq hydroxide.[2083] Triallylborane reacts with the carbonyl group of lactams, and after treatment with methanol and then aq NaOH gives the *gem*-diallyl amine: 2-pyrrolidinone $\rightarrow$ 2,2-diallylpyrrolidine.[2084] *N,N*-Disubstituted carbamates ($X = OR^2$) and carbamoyl chlorides ($X = Cl$) react with 2 molar equivalents of an alkyl- or aryllithium or *Grignard reagent* to give symmetrical ketones, in which both R groups are derived from the organometallic compound: R_2'NCOX + 2 RMgX $\rightarrow R_2CO$.[2085] *N,N*-Disubstituted amides give ketones in high yields when treated with alkyllanthanum triflates [$RLa(OTf)_2$].[2086]

Other organometallic reagents give acyl substitution. Sodium naphthalenide reacts with esters to give naphthyl ketones.[2087] Trimethylaluminum, which exhaustively methylates ketones (Reaction **16-24**), also exhaustively methylates carboxylic acids to give *tert*-butyl compounds[2088] (see also, Reaction **10-63**). Trimethylaluminum reacts with esters to form ketones, in the presence of *N,N'*-dimethylethylenediamine.[2089] Trialkylboranes have been used to convert thioesters to ketones.[2090] Thioesters ($RCOSR'$) react with arylboronic acids, in the presence of a Pd catalyst, to give the corresponding ketone,[2091] and esters react similarly with arylboronic acids (a Pd catalyst)[2092] or arylboronates (a Ru catalyst).[2093] Arylboronic acids also react with dialkyl anhydrides, with a Rh[2094] or a Pd catalyst,[2095] to give the ketone. Thioesters are converted to ketones with organoindium compounds.[2096] Thioesters give good yields of ketones when treated with lithium dialkylcopper reagents (R_2^2CuLi, $R'' =$ primary or secondary alkyl or aryl).[2097] Organozinc reagents convert thioesters to ketones.[2098] Diaryl- or dialkylzinc reagents react with anhydrides and a Pd[2099] or a Ni catalyst[2100] to give the ketone. The reaction of alkylzinc halides and thioesters leads to ketones in the presence of 1.5% Pd/C,[2101] in what has been called *Fukuyama coupling*.[2102] Note that in the presence of a SmI_2 catalyst and 2 molar equivalents of

allyl bromide, lactones were converted to the diallyl diol.[2103] Aryl iodides react with acetic anhydride, with a Pd catalyst, to give the aryl methyl ketone.[2104]

Carboxylic esters can be converted to their homologues (RCOOEt → RCH_2COOEt) by treatment with Br_2CHLi followed by BuLi at -90 °C. The ynolate (RC≡COLi) is an intermediate.[2105] If the ynolate is treated with 1,3-cyclohexadiene, followed by $NaBH_4$, the product is the alcohol RCH_2CH_2OH.[2106]

Note that acyl benzotriazoles react with β-keto esters to give diketones via acyl substitution.[2107] Acyl cyanides [RC(=O)CN] react with allylic bromides and In metal to give the corresponding ketone.[2108] Acyl benzotriazoles have been coupled with SmI_2 to give the 1,2-diketone.[2109] α-Cyanoketones (acyl nitriles) were coupled with YbI_2 in a similar manner.[2110]

Vinyl organometallic reagents can be added to acyl derivatives. Reaction of an alkyne with Cp_2ZrEt_2 generates the vinyl zirconium reagent, which react with ethyl chloroformate to give an α,β-unsaturated ester.[2111]

16-83 The Coupling of Acyl Halides

De-halogen-coupling

$$2\,RCOCl \xrightarrow{\text{pyrophoric Pb}} RCOCOR$$

Acyl halides can be coupled with pyrophoric lead to give symmetrical α-diketones in a *Wurtz-type reaction*.[2112] The reaction has been performed with R = Me and Ph. Samarium iodide[2113] gives the same reaction. The photochemical coupling of acyl iodides gives α-diketones.[2114] Benzoyl chloride was coupled to give benzil by subjecting it to ultrasound in the presence of Li wire: 2 PhCOCl + Li → PhCOCOPh.[2115]

Unsymmetrical α-diketones (RCOCOR′) have been prepared by treatment of an acyl halide (RCOCl) with an acyltin reagent $R'COSnBu_3$, with a Pd complex catalyst.[2116]

16-84 Acylation at a Carbon Bearing an Active Hydrogen

Bis(ethoxycarbonyl)methyl-de-halogenation, and so on

This reaction is similar to **10-67**, but there are fewer examples.[2117] Either Z or Z′ may be any of the electron-withdrawing groups listed in Reaction **10-67** (CO_2R, COR, CN, etc.)[2118] Anhydrides react similarly but are used less often. The product contains three Z groups, since RCO is a Z group. One or two of these can be cleaved (Reactions **12-40** and **12-43**). In this way, a compound ZCH_2Z' can be converted to ZCH_2Z[2] or an acyl halide (RCOCl) to a methyl ketone ($RCOCH_3$). O-Acylation is sometimes a side reaction.[2119] When thallium(I) salts of ZCH_2Z' are used, it is possible to achieve regioselective acylation at either the C or the O position. For example, treatment of the thallium(I) salt of $MeCOCH_2COMe$ with acetyl chloride at -78 °C gave >90% O-acylation, while acetyl fluoride at room temperature gave >95% C-acylation.[2120] The use of an alkyl chloroformate gives triesters.[2121]

The application of this reaction to simple ketones[2122] (in parallel with Reaction **10-68**) requires a strong base (e.g., $NaNH_2$ or Ph_3CNa) and is often complicated by O-acylation, which in many cases becomes the principal pathway because acylation at the oxygen is usually much faster. It is possible to increase the proportion of C-acylated product by employing an excess (2–3 molar equivalents) of enolate anion (and adding the substrate to this, rather than vice versa), by the use of a relatively nonpolar solvent and a metal ion (e.g., Mg^{2+}), which is tightly associated with the enolate oxygen atom, by the use of an acyl halide rather than an anhydride,[2123] and by working at low temperatures.[2124] In cases where the use of an excess of enolate anion results in C-acylation, it is because O-acylation takes place first, and the O-acylated product (an enol ester) is then C-acylated. Simple ketones can also be acylated by treatment of their silyl enol ethers with an acyl chloride in the presence of $ZnCl_2$ or $SbCl_3$.[2125] Ketones can be acylated by anhydrides to give β-diketones, with BF_3 as catalyst.[2126] Simple esters (RCH_2CO_2Et) can be acylated at the α carbon (at –78 °C) if a strong base (e.g., lithium *N*-isopropylcyclohexylamide) is used to remove the proton.[2127]

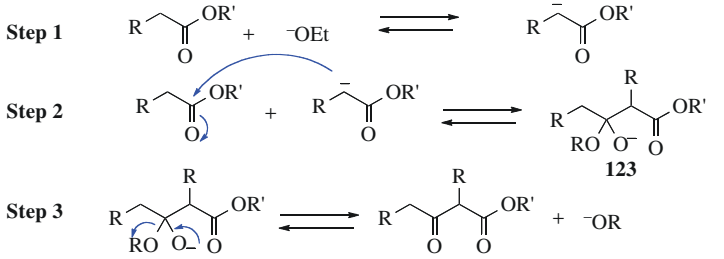
16-85 Acylation of Carboxylic Esters by Carboxylic Esters: The Claisen and Dieckmann Condensations

Alkoxycarbonylalkyl-de-alkoxy-substitution

When carboxylic esters containing an α hydrogen are treated with a strong base (e.g., sodium ethoxide), a condensation occurs to give a β-keto ester via an ester enolate anion.[2129] This reaction is called the *Claisen condensation*. When it is carried out with a mixture of two different esters, each of which possesses an α hydrogen (this reaction is called a *mixed-Claisen* or a *crossed-Claisen condensation*), a mixture of all four products is generally obtained and the reaction is seldom useful synthetically.[2130] However, if only one of the esters has an α hydrogen, the mixed reaction is frequently satisfactory. Among esters lacking α hydrogen atoms (hence acting as the substrate ester) that are commonly used in this way are esters of aromatic acids, and ethyl carbonate and ethyl oxalate. When the ester enolate reacts with ethyl carbonate, the product is a malonic ester, and reaction with ethyl formate introduces a formyl group. *Claisen condensation* of phenyl esters with $ZrCl_4$ and diisopropylethylamine (*Hünigs base*) give the corresponding keto ester.[2131] Titanium compounds catalyze a *crossed-Claisen condensation*.[2132] Boron(III) compounds also catalyzed ester condensation reactions.[2133]

As with ketone enolate anions (see Reaction **16-34**), the use of amide bases under kinetic control conditions (strong base with a weak conjugate acid, aprotic solvents, low temperatures), allows the *mixed-Claisen condensation* to proceed. Self-condensation of the lithium enolate with the parent ester is a problem when LDA is used as a base,[2134] but this is minimized with LICA.[2135] Note that solvent-free *Claisen condensation* reactions have been reported.[2136] There is a *retro-Claisen condensation*, catalyzed by indium.[2137]



122

When the two ester groups involved in the condensation are in the same molecule, the product is a cyclic β-keto ester (**122**) and the reaction is called the *Dieckmann*

condensation:[2138] The *Dieckmann condensation* is most successful for the formation of 5-, 6-, and 7-membered rings, but yields for rings of 9–12 members are very low or nonexistent. Reactions that form large rings are generally assisted by high dilution. A solvent-free *Dieckmann condensation* has been reported on solid potassium *tert*-butoxide.[2139] *Dieckmann condensation* of unsymmetrical substrates can be made regioselective by the use of solid-phase supports.[2140] The *Dieckmann condensation* has also been done using $TiCl_3/NBu_3$ with a TMSOTf catalyst.[2141] A *Dieckmann-like condensation* was reported where an α,ω-dicarboxylic acid was heated to 450 °C on graphite, with microwave irradiation, to give the cyclic ketone.[2142]

The mechanism of the *Claisen* and *Dieckmann condensations* (steps 1–3) is the ordinary *tetrahedral mechanism*,[2143] with one molecule of ester being converted to a nucleophile by the base and the other serving as the substrate. This reaction illustrates the striking difference in behavior between carboxylic esters on the one hand and aldehydes and ketones on the other. When a carbanion (e.g., an enolate anion) is added to the carbonyl group of an aldehyde or ketone (Reaction **16-38**), the H or R is not lost, since these groups are much poorer leaving groups than OR. Instead, the intermediate similar to **123** adds a proton at the oxygen to give a hydroxy compound.

In contrast to Reaction **10-67**, ordinary esters react quite well; that is, two Z groups are not needed. A lower degree of acidity is satisfactory because it is not necessary to convert the attacking ester entirely to its ion. Step 1 is an equilibrium that lies well to the left, but the small amount of enolate anion formed is sufficient to attack the readily approachable ester substrate. All the steps are in equilibria. The reaction proceeds because the product is converted to its conjugate base by the base present (i.e., a β-keto ester is a stronger acid than an alcohol):

The use of a stronger base (e.g., $NaNH_2$, NaH, or KH),[2144] often increases the yield. For some esters, stronger bases *must* be used, since sodium ethoxide is ineffective. Among these are

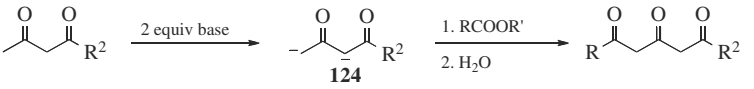
16-86 Acylation of Ketones and Nitriles by Carboxylic Esters

α-Acylalkyl-de-alkoxy-substitution

Carboxylic esters can be treated with ketones to give β-diketones. The reaction is so similar that it is sometimes also called the *Claisen reaction*, but this usage may be confusing. A strong base (e.g., sodium amide or sodium hydride) is required. Yields can be increased by the catalytic addition of crown ethers.[2146] Esters of formic acid (R = H) give β-keto aldehydes and ethyl carbonate gives β-keto esters. β-Keto esters can also be obtained by treating the lithium enolates of ketones with methyl cyanoformate (MeOCOCN,[2147] in this case CN is the leaving group) and by treating ketones with KH and diethyl dicarbonate [$(EtOCO)_2O$].[2148] This reaction has been used to effect cyclization, especially to prepare five- and six-membered rings. Nitriles are frequently used instead of ketones, the products being β-keto nitriles, as shown.



Other nucleophilic carbon reagents (e.g., acetylide ions) and ions derived from α-methylpyridines have also been used. A particularly useful nucleophile is the methylsulfinyl carbanion ($CH_3SOCH_2^-$),[2149] the conjugate base of DMSO, since the β-keto sulfoxide produced can easily be reduced to a methyl ketone (see Reaction **10-67**). The methylsulfonyl carbanion ($CH_2SO_2CH_2^-$), the conjugate base of dimethyl sulfone, behaves similarly,[2150] and the product can be similarly reduced. Certain carboxylic esters, acyl halides, and DMF will acylate 1,3-dithianes[2151] (see Reaction **10-71**) to give, after oxidative hydrolysis with NBS or NCS, α-keto aldehydes or α-diketones.[2152]

As in Reaction **10-67**, a ketone is deprotonated at the most acidic proton first and the second most acidic position after that if 2 equivs of base are used, to give dianion **124**.

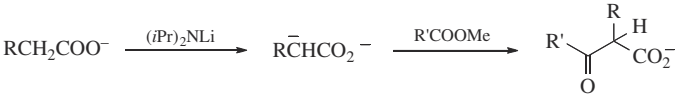
[2152] See Corey, E.J.; Erickson, B.W. *J. Org. Chem.* ***1971****, 36*, 3553.

Thus, β-diketones have been converted to 1,3,5-triketones.[2153]



124

Side reactions are condensation of the ketone with itself (**16-34**), of the ester with itself, and of the ketone with the ester but with the ester supplying the α-position (**16-36**). The mechanism is the same as in Reaction **16-85**.[2154]

OS **I**, 238; **II**, 126, 200, 287, 487, 531; **III**, 17, 251, 291, 387, 829; **IV**, 174, 210, 461, 536; **V**, 187, 198, 439, 567, 718, 747; **VI**, 774; **VII**, 351.

16-87 Acylation of Carboxylic Acid Salts

α-Carboxyalkyl-de-alkoxy-substitution

As seen previously (Reaction **10-70**), dianions of carboxylic acids can be alkylated in the α position. These ions can also be acylated on treatment with a carboxylic ester[2155] to give salts of β-keto acids. As in Reaction **10-70**, the carboxylic acid can be of the form RCH_2CO_2H or RR^2CHCO_2H. Since β-keto acids are so easily converted to ketones (Reaction **12-40**), this is also a method for the preparation of ketones ($R'COCH_2R$ and $R'COCHRR^2$), where R′ can be primary, secondary, or tertiary alkyl, or aryl. If the ester is ethyl formate, an α-formyl carboxylate salt (R′ = H) is formed, which on acidification spontaneously decarboxylates into an aldehyde.[2156] This method accomplishes the conversion $RCH_2CO_2H \rightarrow RCH_2CHO$, and is an alternative to the reduction methods discussed in Reaction **19-39**. When the carboxylic acid is of the form RR^2CHCO_2H, better yields are obtained by acylating with acyl halides rather than esters.[2157]

16-88 Preparation of Acyl Cyanides

Cyano-de-halogenation

$$RCOX + CuCN \longrightarrow RCOCN$$

Acyl cyanides[2158] can be prepared by treatment of acyl halides with copper cyanide. The mechanism could be free radical or nucleophilic substitution. The reaction has also been accomplished with thallium(I) cyanide,[2159] with Me_3SiCN and an $SnCl_4$ catalyst,[2160] and with Bu_3SnCN,[2161] but these reagents are successful only when R = aryl or tertiary alkyl.

Potassium cyanide has also been used, along with ultrasound,[2162] as has NaCN with phase-transfer catalysts.[2163]

OS **III**, 119.

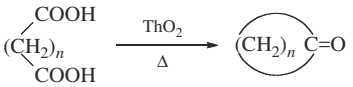
16-89 Preparation of Diazo Ketones

Diazomethyl-de-halogenation

$$RCOX + CH_2N_2 \longrightarrow RCOCHN_2$$

The reaction between acyl halides and diazomethane is of wide scope and is the best way to prepare diazo ketones.[2164] Diazomethane must be present in excess or the HX produced will react with the diazo ketone (Reaction **10-52**). This reaction is the first step of the *Arndt–Eistert synthesis* (**18-8**). Diazo ketones can also be prepared directly from a carboxylic acid and diazomethane or diazoethane in the presence of DCC.[2165]

OS **III**, 119; **VI**, 386, 613; **VIII**, 196.



16-90 Ketonic Decarboxylation[2166]

Alkyl-de-hydroxylation

$$2 \quad RCOOH \xrightarrow[ThO_2]{400-500^\circ C} RCOR + CO_2$$

Carboxylic acids can be converted to symmetrical ketones by pyrolysis in the presence of thorium oxide. In a mixed reaction, formic acid and another acid heated over thorium oxide give aldehydes. Mixed alkyl aryl ketones have been prepared by heating mixtures of ferrous salts.[2167] When the R group is large, the methyl ester rather than the acid can be decarbmethoxylated over thorium oxide to give the symmetrical ketone.

The reaction has been performed on dicarboxylic acids, whereupon cyclic ketones are obtained:

This process, called *Ruzicka cyclization*, is good for the preparation of rings of six and seven members and, with lower yields, of C_8–C_{10} to C_{30} cyclic ketones.[2168]

Not much work has been done on the mechanism of this reaction. However, a free radical mechanism has been suggested on the basis of a thorough study of all the side products.[2169]

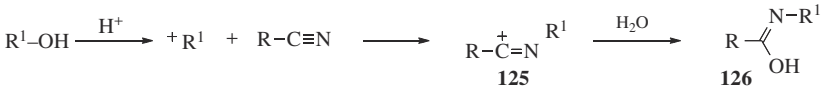
16.B.iii. Reactions in which Carbon Adds to the Heteroatom



A. Oxygen Adding to the Carbon

16-91 The Ritter Reaction

***N*-Hydro,*N*-alkyl-*C*-oxo-biaddition**

Alcohols can be added to nitriles in an entirely different manner from that seen in Reaction **16-9**. In this reaction, the alcohol is converted by a strong acid to a carbocation, which is attacked by the nucleophilic nitrogen atom to give **125**. Subsequent addition of water to the electrophilic carbon atom leads to the enol form of the amide (see Reaction **126**), which tautomerizes (Sec. 2.N.i) to the *N*-alkyl amide.

Only alcohols that give rise to fairly stable carbocations react (secondary, tertiary, benzylic, etc.); non-benzylic primary alcohols do not give the reaction. The carbocation need not be generated from an alcohol, but may come from protonation of an alkene or from other sources. In any case, the reaction is called the *Ritter reaction*.[2170] Lewis acids [e.g., $Mg(HSO_4)_2$] have been used to promote the reaction.[2171] Highly sterically hindered nitriles have been converted to *N*-methyl amides by heating with methanol and sulfuric acid.[2172] Hydrogen cyanide also gives the reaction, the product being a formamide. Trimethylsilyl cyanide has also been used.[2173]

Since the amides (especially the formamides) are easily cleaved to amines under hydrolysis conditions, the *Ritter reaction* provides a method for achieving the conversions $R'OH \rightarrow R'NH_2$ (see **10-32**) and alkene $\rightarrow R'NH_2$ (see **15-8**) in those cases, where R′ can form a relatively stable carbocation. The reaction is especially useful for the preparation of tertiary alkyl amines because there are few alternate ways of preparing these compounds. The reaction can be extended to primary alcohols by treatment with triflic anhydride[2174] or Ph_2CCl^+ $SbCl_6^-$ or a similar salt[2175] in the presence of the nitrile. A mixture of P_2O_5 and silica gel has been used to mediate the *Ritter reaction*.[2176] There is a Nafion-catalyzed,

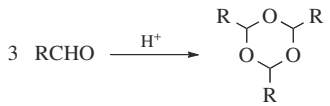
microwave assisted variation,[2177] as well as $FeCl_3$ catalyzed[2178] and iodine-catalyzed[2179] reactions.

Alkenes of the form RCH=CHR′ and RR′C=CH_2 add to nitriles in the presence of mercuric nitrate to give, after treatment with $NaBH_4$, the same amides that would be obtained by the *Ritter reaction*.[2180] This method has the advantage of avoiding strong acids.



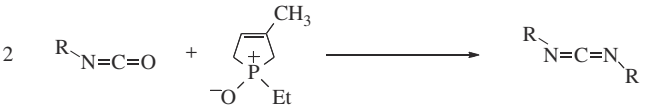
Benzylic compounds (e.g., ethylbenzene) react with alkyl nitriles, ceric ammonium nitrate, and a catalytic amount of *N*-hydroxysuccinimide to give the *Ritter* product, the amide.[2181]

The *Ritter reaction* can be applied to cyanamides RNHCN to give ureas (RNHCONHR′).[2182]

OS **V**, 73, 471.

16-92 The Addition of Aldehydes to Aldehydes

When catalyzed by acids, low-molecular-weight aldehydes add to each other to give cyclic acetals, the most common product being the trimer.[2183] The cyclic trimer of formaldehyde is called *trioxane*,[2184] and that of acetaldehyde is known as *paraldehyde*. Under certain conditions, it is possible to get tetramers[2185] or dimers. Aldehydes can also polymerize to linear polymers, but a small amount of water is required to form hemiacetal groups at the ends of the chains. The linear polymer formed from formaldehyde is called *paraformaldehyde*. Since trimers and polymers of aldehydes are acetals, they are stable to bases, but can be hydrolyzed by acids. Because formaldehyde and acetaldehyde have low boiling points, it is often convenient to use them in the form of their trimers or polymers.



A slightly related reaction involves nitriles, which can be trimerized with various acids, bases, or other catalysts to give triazines (see OS **III**, 71).[2186] Here HCl is most often used. Most nitriles with an α hydrogen do not give the reaction.

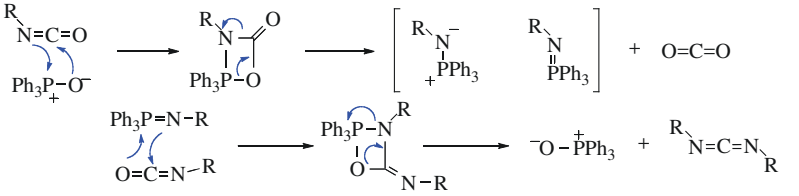
B. Nitrogen Adding to the Carbon



16-93 The Addition of Isocyanates to Isocyanates (Formation of Carbodiimides)

Alkylimino-de-oxo-bisubstitution

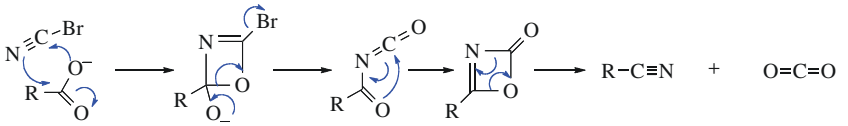
127

The treatment of isocyanates with 3-methyl-1-ethyl-3-phospholene-1-oxide (**127**) is a useful method for the synthesis of carbodiimides[2187] in good yields.[2188] The mechanism does not simply involve the addition of one molecule of isocyanate to another, since the kinetics are first order in isocyanate and first order in catalyst. The following mechanism has been proposed (the catalyst is here represented as $R_3P^+—O^-$:[2189]

According to this mechanism, one molecule of isocyanate undergoes addition to C=O, and the other addition to C=N. Evidence is that ^{18}O labeling experiments have shown that each molecule of CO_2 produced contains one oxygen atom derived from the isocyanate and one from **127**,[2190] precisely what is predicted by this mechanism. Certain other catalysts are also effective.[2191] High load, soluble oligomeric carbodiimides have been prepared.[2192]

OS **V**, 501.

16-94 The Conversion of Carboxylic Acid Salts to Nitriles



Nitrilo-de-oxido,oxo-tersubstitution

$$RCOO^- + BrCN \xrightarrow{250-300^\circ C} RCN + CO_2$$

Salts of aliphatic or aromatic carboxylic acids can be converted to the corresponding nitriles by heating with BrCN or ClCN. Heating with acetonitrile in sulfuric acid also gave the nitrile.[2193] Despite appearances, this is not a substitution reaction. When $R^{14}COO^-$ was used, the label appeared in the nitrile, not in the CO_2,[2194] and optical activity in R was retained.[2195] The acyl isocyanate (RCON=C=O) could be isolated from the reaction

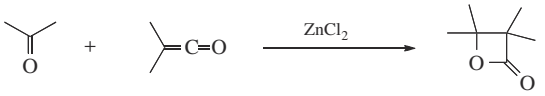
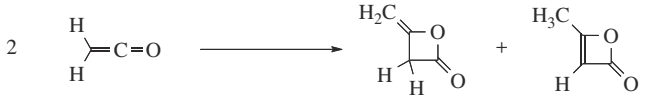
mixture; hence the following mechanism was proposed:[2194]



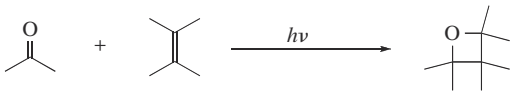
C. Carbon Adding to the Carbon



The reactions in this group are cycloadditions.

16-95 The Formation of β-Lactones and Oxetanes

(2+2)*OC*,*CC-cyclo*-[oxoethylene]-1/2/addition



Aldehydes, ketones, and quinones react with ketenes to give β-lactones,[2196] diphenylketene being used most often.[2197] The reaction is catalyzed by Lewis acids, and without them most ketenes do not give adducts because the adducts decompose at the high temperatures necessary when no catalyst is used. When ketene was added to chloral (Cl_3CCHO) in the presence of the chiral catalyst (+)-quinidine, one enantiomer of the β-lactone was produced with excellent enantioselectivity.[2198] Enantioselective β-lactone formation was accomplished using chiral oxazaborolidines.[2199] The use of a chiral Al catalyst also led to β-lactones with good syn selectivity and good enantioselectivity.[2200] Other di- and trihalo aldehydes and ketones also give the reaction enantioselectively, with somewhat lower enantioselectivity.[2201] Ketene adds to another molecule of itself:

This dimerization is so rapid that ketene does not form β-lactones with aldehydes or ketones, except at low temperatures. Other ketenes dimerize more slowly. In these cases, the major dimerization product is not the β-lactone, but a cyclobutanedione (see Reaction **15-63**). However, the proportion of ketene that dimerizes to β-lactone can be increased by the addition of catalysts (e.g., triethylamine or triethyl phosphite).[2202] Ketene acetals [$R_2C{=}C(OR')_2$] add to aldehydes and ketones in the presence of $ZnCl_2$ to give the

corresponding oxetanes.[2203]

Ordinary aldehydes and ketones can add to alkenes, under the influence of UV light, to give oxetanes. Quinones also react to give spirocyclic oxetanes.[2204] This reaction, called the *Paterno–Büchi reaction*,[2205] is similar to the photochemical dimerization of alkenes discussed at Reaction **15-63**. In general, the mechanism consists of the addition of an excited state of the carbonyl compound to the ground state of the alkene. Both singlet (S_1)[2206] and $n,\pi*$ triplet[2207] states have been shown to add to alkenes to give oxetanes. A diradical intermediate $\cdot O—C—C—C\cdot$[2208] has been detected by spectroscopic methods.[2209] Yields in the *Paterno–Büchi reaction* are variable, ranging from very low to fairly high (90%). The reaction can be highly diastereoselective,[2210] and allylic alcohols were shown to react with aldehydes to give an oxetane with syn selectivity.[2211] There are several side reactions. When the reaction proceeds through a triplet state, it can in general be successful only when the alkene possesses a triplet energy comparable to, or higher than, the carbonyl compound; otherwise energy transfer from the excited carbonyl group to the ground-state alkene can take place (triplet–triplet photosensitization, see Sec. 7.A.vi).[2212] In most cases, quinones react normally with alkenes, giving oxetane products, but other α,β-unsaturated ketones usually give preferential cyclobutane formation (Reaction **15-63**). Aldehydes and ketones also add photochemically to allenes to give the corresponding alkylideneoxetanes and dioxaspiro compounds:[2213] Aldehydes add to silyl enol ethers.[2214] An intramolecular reaction of ketones was reported to give a bicyclic oxetane via

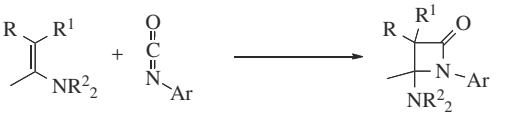
16-96 The Formation of β-Lactams

(2+2)*NC*,*CC*-*cyclo*-[oxoethylene]-1/2/addition

Ketenes add to imines to give β-lactams.[2216] The reaction is generally carried out with ketenes of the form $R_2C{=}C{=}O$. It has not been successfully applied to RCH=C=O, except when these are generated *in situ* by decomposition of a diazo ketone (the *Wolff rearrangement*, Reaction **18-8**) in the presence of the imine. It has been done with ketene, but the more usual course with this reagent is an addition to the enamine tautomer of the substrate. Thioketenes[2217] ($R_2C{=}C{=}S$) give β-thiolactams.[2218] Imines also form β-lactams when treated with (1) zinc (or another metal[2219]) and an α-bromo ester (*Reformatsky* conditions, **16-28**),[2220] or (2) the chromium carbene complexes $[(CO)_5Cr{=}C(Me)OMe]$.[2221] The latter method has been used to prepare optically active β-lactams.[2222] Ketenes have also been added to certain hydrazones (e.g., $PhCH{=}NNMe_2$) to give N-amino β-lactams.[2223] A polymer-bound pyridinium salt facilitates β-lactam formation from carboxylic acids and imines.[2224] α-Chloroimines have been used as chiral inductors in this reaction.[2225]



N-Tosyl imines react with ketenes, Proton Sponge (Sec. 8.A.i) and a chiral amine to give the *N*-tosyl β-lactam with good enantioselectivity.[2226] A chiral ferrocenyl catalyst also

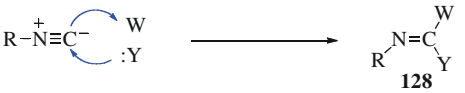
gives good enantioselectivity,[2227] and chiral ammonium salts[2228] or chiral cinchona alkaloids[2229] have been used as catalysts. A catalytic amount of benzoyl quinine gives β-lactams with good enantioselectivity.[2230]

An intramolecular version of this ketene–imine reaction is known.[2231]

Like the similar cycloaddition of ketenes to alkenes (Reaction **15-63**), most of these reactions probably take place by the diionic mechanism *c* (See **15-63**).[2232] β-Lactams have also been prepared in the opposite manner by the addition of enamines to isocyanates:[2233]

The reactive compound chlorosulfonyl isocyanate[2234] ($ClSO_2NCO$) forms β-lactams even with unactivated alkenes,[2235] as well as with imines,[2236] allenes,[2237] conjugated dienes,[2238] and cyclopropenes.[2239] With microwave irradiation, alkyl isocyanates also react.[2240]

α-Diazo ketones react with imines and microwave irradiation to give β-lactams.[2241] Allylic phosphonate esters react with imines, in the presence of a Pd catalyst, to give β-lactams.[2242] Alkynyl reagents (e.g., $BuC{\equiv}CO^-Li^+$) react with imines to form β-lactams.[2243] Imines and benzylic halides react to give β-lactams in the presence of CO and a Pd catalyst.[2244] Conjugated amides react with NBS and 20% sodium acetate to give an α-bromo β-lactam.[2245] A different approach to β-lactams heated aziridines with CO and a Co catalyst.[2246] Aziridines also react with CO and a dendrimer catalyst to such a β-lactam.[2247]



β-Thiolactams are prepared from aryl isothiocyanates.[2248]

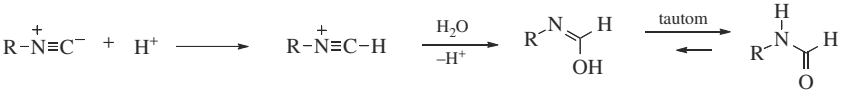
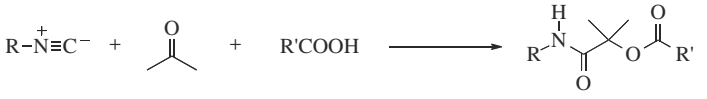
16.B.iv. Addition to Isocyanides[2249]

Addition to R–$^{+}$N≡C^{-} is not a matter of a species with an electron pair adding to one atom and a species without a pair adding to the other, as is addition to the other types of double and triple bonds in this chapter and Chapter 15. In these additions, the electrophile and the nucleophile *both add to the carbon*. No species add to the nitrogen, which, however, loses its positive charge by obtaining as an unshared pair one of the triple-bond pairs of electrons to give **128**. In most of the reactions considered below, **128** undergoes a further reaction, so the product is of the form R—$\bar{\text{N}}$H—CR_3.



16-97 The Addition of Water to Isocyanides

1/ *N*,2/*C*-Dihydro-2/*C*-oxo-biaddition



Formamides can be prepared by the acid-catalyzed addition of water to isocyanides. The mechanism is probably[2250]

The reaction has also been carried out under alkaline conditions, with hydroxide in aq dioxane.[2251] The mechanism here involves nucleophilic attack by hydroxide at the carbon atom. An intramolecular addition of an alkyne (in an ortho alkynyl phenyl isonitrile) to the carbon of an isonitrile occurred with heating in methanol to give quinoline derivatives.[2252]

16-98 The Passerini and Ugi Reactions[2253]

1/*N*-Hydro-2/*C*-(α-acyloxyalkyl),2/*C*-oxo-biaddition

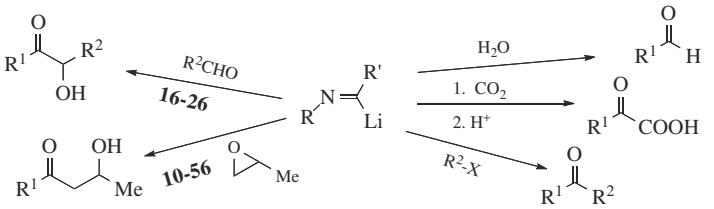
When an isocyanide is treated with a carboxylic acid and an aldehyde or ketone, an α-acyloxy amide is the product in what is called the *Passerini reaction*. A $SiCl_4$ mediated reaction in the presence of a chiral bis(phosphoramide) gives an α-hydroxy amide with good enantioselectivity.[2254] There is a solvent-free *Passerini reaction*[2255] and ionic liquids[2256] can be used. The following mechanism has been postulated for the basic reaction:[2257]

If ammonia or an amine is also added to the mixture (in which case the reaction is known as the *Ugi reaction*, or the *Ugi four-component condensation*), the product is R′(C=C)NH—C—(C=O)NHR [the corresponding bis(amide) from NH_3] or R′(C=C)NR′—C—(C=O)NHR (from a primary amine R^2NH_2). There is a catalytic *three-component Ugi reaction*.[2258] Repetitive *Ugi reactions* are known.[2259] This product probably arises from a reaction between the carboxylic acid, the isocyanide, and the *imine* formed from the aldehyde or ketone and ammonia or the primary amine. "Isocyanide-free" *Ugi reactions* use alkyl halides/silver cyanide and KCN to generate the isocyanide *in situ*.[2260] The use of an *N*-protected amino acid[2261] or peptide as the carboxylic acid component and/or the use of an isocyanide containing a C-protected carboxyl group allows the reaction to be used for peptide synthesis.[2262] Rare earth metal triflates catalyze this reaction.[2263]

16-99 The Formation of Metalated Aldimines



1/1/Lithio-alkyl-addition

Isocyanides that do not contain an α hydrogen react with alkyllithium compounds,[2264] as well as with *Grignard reagents*, to give lithium (or magnesium) aldimines.[2265] These

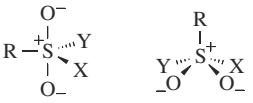
metalated aldimines are versatile nucleophiles and react with various substrates as follows:



The reaction therefore constitutes a method for converting an organometallic compound (R′M) to an aldehyde (R′CHO, see also, Reaction **12-33**), an α-keto acid,[2266] a ketone R′COR (see also, Reaction **12-33**), an α-hydroxy ketone, or a β-hydroxy ketone. In each case, the C=N bond is hydrolyzed to a C=O bond (Reaction **16-2**).

In a related reaction, isocyanides can be converted to aromatic aldimines by treatment with an iron complex followed by irradiation in benzene solution: RNC + C_6H_6 → PhCH=NR.[2267]

OS **VI**, 751.

16.B.v. Nucleophilic Substitution at a Sulfonyl Sulfur Atom[2268]

Nucleophilic substitution at RSO_2X is similar to attack at RCOX. Many of the reactions are essentially the same, though sulfonyl halides are less reactive than halides of carboxylic acids.[2269] The mechanisms[2270] are not identical, because a "tetrahedral" intermediate in this case (**129**) would have five groups on the central atom. This is possible since sulfur can accommodate up to 12 electrons in its valence shell, but it seems more likely that these mechanisms more closely resemble the S_N2 mechanism, with a trigonal-bipyramidal transition state (**130**). There are two major experimental results leading to this conclusion.

129 **130**

1. The stereospecificity of this reaction is more difficult to determine than that of nucleophilic substitution at a saturated carbon, where chiral compounds are relatively easy to prepare. Recall (Sec. 4.C, category 2) that optical activity is possible in a compound of the form RSO_2X if one oxygen is ^{16}O and the other is ^{18}O. When a sulfonate ester possessing this type of chirality was converted to a sulfone by reaction with a *Grignard reagent* (**16-105**), inversion of configuration was found.[2271] This is not incompatible with an intermediate (e.g., **129**), but it is in good accord with an S_N2-like mechanism with backside attack.

[2270] See Gordon, I.M.; Maskill, H.; Ruasse, M. *Chem. Soc. Rev.* ***1989****, 18*, 123.
[2271] Sabol, M.A.; Andersen, K.K. *J. Am. Chem. Soc.* ***1969****, 91,* 3603. See also, Jones, M.R.; Cram, D.J. *J. Am. Chem. Soc.* ***1974****, 96,* 2183.

2. More direct evidence against **129** (though still not conclusive) was found in an experiment involving acidic and basic hydrolysis of aryl arenesulfonates, where it has been shown by the use of ^{18}O that an intermediate like **129** is not reversibly formed, since ester recovered when the reaction was stopped before completion contained no ^{18}O when the hydrolysis was carried out in the presence of labeled water.[2272]

Other evidence favoring the S_N2-like mechanism comes from kinetics and substituent effects.[2273] However, evidence for the mechanism involving **129** is that the rates did not change much with changes in the leaving group[2274] and the ρ values were large, indicating that a negative charge builds up in the transition state.[2275]

In certain cases in which the substrate carries an α hydrogen, there is strong evidence[2276] that at least some of the reaction takes place by an elimination–addition mechanism (E1cB, similar to the one shown in Reaction **16-69**), going through a *sulfene* intermediate,[2277] as in the reaction between methanesulfonyl chloride and aniline.

$$CH_3—SO_2Cl \xrightarrow{\text{base}} \underset{\text{A sulfene}}{CH_2=SO_2} \xrightarrow{PhNH_2} CH_3—SO_2—NHPh$$

In the special case of nucleophilic substitution at a sulfonic ester (RSO_2OR'), where R′ is alkyl, R′–O cleavage is much more likely than S—O cleavage because the OSO_2R group is such a good leaving group (Sec. 10.G.iii).[2278] Many of these reactions have been considered previously (e.g., Reactions **10-4** and **10-10**) as nucleophilic substitutions at an alkyl carbon atom and not at a sulfur atom. However, when R′ is aryl, then the S—O bond is much more likely to cleave because of the low tendency of aryl substrates for nucleophilic substitution.[2279]

The order of nucleophilicity toward a sulfonyl sulfur has been reported as $OH^- > RNH_2 > N_3 > F^- > AcO^- > Cl^- > H_2O > I^-$.[2280] This order is similar to that at a carbonyl carbon (Sec. 10.G.ii). Both of these substrates can be regarded as relatively hard acids, compared to a saturated carbon that is considerably softer and has a different order of nucleophilicity (Sec. 10.G.ii).

Sulfonyl chlorides as well as esters and amides of sulfonic acids can be hydrolyzed to the corresponding acids. Sulfonyl chlorides can be hydrolyzed with water or with an alcohol in the absence of acid or base. Basic catalysis is also used, though of course the salt is the product obtained. Esters are readily hydrolyzed, many with water or dilute alkali. This is the same reaction as **10-4**, and usually involves R′—O cleavage, except when R′ is aryl. In some cases, retention of configuration has been shown at alkyl R′, indicating S—O cleavage.[2281] Sulfonamides are generally *not* hydrolyzed by alkaline treatment, not even with hot concentrated alkali. Acids, however, do hydrolyze sulfonamides, but less readily than they do sulfonyl halides or sulfonic esters. Of course, ammonia or the amine appears as the salt. However, sulfonamides can be hydrolyzed with base if the solvent is HMPA.[2282]

Magnesium in methanol has been used to convert sulfonate esters to the parent alcohol.[2283] Likewise, $CeCl_3{\bullet}7\ H_2O$—NaI in acetonitrile converted aryl tosylates to the parent phenol derivative.[2284]

OS **I**, 14; **II**, 471; **III**, 262; **IV**, 34; **V**, 406; **VI**, 652, 727. Also see, OS **V**, 673; **VI**, 1016.

16-101 Attack by OR: Formation of Sulfonic Esters

***S*-Alkoxy-de-chlorination**, and so on

$$RSO_2Cl + R'OH \xrightarrow{\text{base}} RSO_2OR'$$

$$RSO_2NR_2'' + R'OH \xrightarrow{\text{base}} RSO_2OR' + NR_2''$$

Sulfonic esters are most frequently prepared by treatment of the corresponding sulfonyl halides with alcohols in the presence of a base.[2285] This procedure is the most common method for the conversion of alcohols to tosylates, brosylates, and similar sulfonic esters. Both R and R′ may be alkyl or aryl. The base is often pyridine or another amine, which functions as a nucleophilic catalyst,[2286] as in the similar alcoholysis of carboxylic acyl halides (Reaction **16-61**). Primary alcohols react most rapidly, and it is often possible to sulfonate a primary OH group selectively in a molecule that also contains secondary or tertiary OH groups. The reaction with sulfonamides has been much less frequently used and is limited to *N,N*-disubstituted sulfonamides; that is, R may not be hydrogen. However, within these limits it is a useful reaction. The nucleophile in this case is actually RO^-. The R′ may be hydrogen (as well as alkyl) if the nucleophile is a phenol, so that the product is RSO_2OAr. Acidic catalysts are used in this case.[2287] Sulfonic acids have been converted directly to sulfonates by treatment with triethyl or trimethyl orthoformate [$HC(OR)_3$], without catalyst or solvent;[2288] and with a trialkyl phosphite [$P(OR)_3$].[2289]

Mono-tosylation of a 1,2-diol was achieved using tosyl chloride and triethylamine, with a tin oxide catalyst.[2290]

16-102 Attack by Nitrogen; Formation of Sulfonamides

***S*-Amino-de-chlorination**

$$RSO_2Cl + NH_3 \longrightarrow RSO_2NH_2$$

Microwave assisted conversion of sulfonic acids to a 2,4,6-trichloro[1,3,5]triazine derivative is followed by formation of the sulfonamide.[2291] The treatment of sulfonyl chlorides with ammonia or amines is the usual way of preparing sulfonamides.[2292] Primary amines give *N*-alkyl sulfonamides, and secondary amines give *N,N*-dialkyl sulfonamides. The reaction is the basis of the *Hinsberg test* for distinguishing between primary, secondary, and tertiary amines. *N*-Alkyl sulfonamides, having an acidic hydrogen, are soluble in alkali, while *N,N*-dialkyl sulfonamides are not. Since tertiary amines are usually recovered unchanged, primary, secondary, and tertiary amines can be told apart. However, the test is limited for at least two reasons.[2293] (1) Many *N*-alkyl sulfonamides in which the alkyl group has six or more carbons are insoluble in alkali, despite their acidic hydrogen,[2294] so that a primary amine may appear to be a secondary amine. (2) If the reaction conditions are not carefully controlled, tertiary amines may not be recovered unchanged.[2289]

A primary or a secondary amine can be protected by reaction with phenacylsulfonyl chloride ($PhCOCH_2SO_2Cl$) to give a sulfonamide ($RNHSO_2CH_2COPh$ or $R_2NSO_2CH_2COPh$).[2295] The protecting group can be removed when desired with zinc and acetic acid. Sulfonyl chlorides react with azide ion to give sulfonyl azides (RSO_2N_3).[2296] Chlorothioformates, [ROC(=S)Cl] react with triethylamine to give the *N,N*-diethylthioamide.[2297]

A quite different synthesis of sulfonamides treated allyltributyltin with PhI=NTs, in the presence of copper(II) triflate.[2298] Another alternative method treats silyl enol ethers with sulfur dioxide, and subsequent reaction with a secondary amine gave the β-sulfonamido ester.[2299]

substrates. Cyanuric acid (2,4,6-trichloro[1,3,5]triazene) serves as a chlorinating agent.[2300] Sulfonyl bromides and iodides have been prepared from sulfonyl hydrazides ($ArSO_2NHNH_2$, themselves prepared by Reaction **16-102**) by treatment with bromine or iodine.[2301] Sulfonyl fluorides are generally prepared from the chlorides, by halogen exchange.[2302]

OS **I**, 84; **IV**, 571, 693, 846, 937; **V**, 196. See also, OS **VII**, 495.

16-104 Attack by Hydrogen: Reduction of Sulfonyl Chlorides

***S*-Hydro-de-chlorination** or ***S* -Dechlorination**

$$2\ \ RSO_2Cl + Zn \longrightarrow (RSO_2)_2Zn \xrightarrow{H^+} 2\ \ RSO_2H$$

Sulfinic acids can be prepared by reduction of sulfonyl chlorides. Though mostly done on aromatic sulfonyl chlorides, the reaction has also been applied to alkyl compounds. Zinc, sodium sulfite, hydrazine, sodium sulfide, and other reducing agents have been used. For reduction of sulfonyl chlorides to thiols, see Reaction **19-78**.

OS **I**, 7, 492; **IV**, 674.

16-105 Attack by Carbon: Preparation of Sulfones

***S*-Aryl-de-chlorination**

$$ArSO_2Cl + Ar'MgX \longrightarrow ArSO_2Ar'$$

Grignard reagents convert aromatic sulfonyl chlorides or aromatic sulfonates to sulfones. Organolithium reagents react with sulfonyl fluorides at –78 °C to give the corresponding sulfone.[2303] Aromatic sulfonates have been converted to sulfones with organolithium compounds,[2304] with aryltin compounds,[2305] with an Fe catalyst,[2306] and with alkyl halides and Zn metal.[2307] Vinylic and allylic sulfones have been prepared by treatment of sulfonyl chlorides with a vinylic or allylic stannane and a Pd complex catalyst.[2308] Alkynyl sulfones can be prepared by treatment of sulfonyl chlorides with trimethylsilylalkynes, with an $AlCl_3$ catalyst.[2309] Note that trifluoromethylsulfones were converted to methyl sulfones by reaction with methylmagnesium bromide.[2310]

Arylboronic acids (Reaction **12-28**) react with sulfonyl chlorides in the presence of $PdCl_2$ to give the corresponding sulfone.[2311] Arylboronic acids also react with sulfinate anions (RSO_2Na) in the presence of $Cu(OAc)_2$ to give the sulfone.[2312]

CHAPTER 17

Eliminations

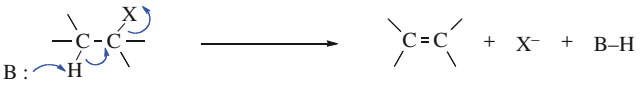
A so-called β-*elimination* reaction occurs when two groups are lost from adjacent atoms so that a new double[1] (or triple) bond is formed. In general, the atom bearing a leaving group is the α, and the other the β atom. In an α-elimination, both groups are lost from the same atom to give a carbene (or a nitrene):

In a γ-elimination, a three-membered ring is formed:

Some of these processes were discussed in Chapter 10. Another type of elimination involves the expulsion of a fragment from within a chain or ring (X—Y—Z → X—Z + Y). Such reactions are called *extrusion reactions*. This chapter discusses β-elimination and extrusion reactions (see Sec. 2.F.vi); however, β-elimination in which both X and W are hydrogen atoms are oxidation reactions. They are treated in Chapter 19.

17.A. MECHANISMS AND ORIENTATION

β-Elimination reactions may be divided into two types: one type taking place largely in solution, the other (pyrolytic eliminations) mostly in the gas phase. In the reactions, one group leaves with its electrons and the other without (i.e., it is pulled off), the latter most



[1] See Williams, J.M.J. *Preparation of Alkenes, A Practical Approach*, Oxford Univ. Press, Oxford, ***1996***.

often being hydrogen. In these cases, the former leaves as the *leaving group or nucleofuge*. For pyrolytic eliminations, there are two principal mechanisms, one pericyclic and the other a free radical pathway. A few photochemical eliminations are also known (the most important is *Norrish-type II* cleavage of ketones, Sec. 7.A.vii), but these are not generally of synthetic importance[2] and will not be discussed further. In most β-eliminations, the new bonds are C=C or C≡C. The discussion of mechanisms is largely confined to these cases.[3] Mechanisms in solution (E2, E1)[4] and E1cB are discussed first. While standard methods are used to examine elimination reactions, new techniques (e.g., the velocity map ion imaging technique) have been used to study ultrafast elimination reactions.[5]

17.A.i. The E2 Mechanism

In the E2 mechanism (elimination, bimolecular), the proton on the β carbon is pulled off by a base, leading to near-simultaneous expulsion of the leaving group (nucleofuge):

The mechanism takes place in one step and is kinetically second order: first order in substrate and first order in base. An *ab initio* study has produced a model for the E2 transition state geometry.[6] The IUPAC designation is $A_{xH}D_HD_N$, or more generally (to include cases where the electrofuge is not hydrogen), $A_nD_ED_N$. It often competes with the S_N2 mechanism (Sec. 10.A.i). With respect to the substrate, the difference between the two pathways is whether the species with the unshared pair attacks the carbon (and thus acts as a nucleophile) or the hydrogen (and thus acts as a base). As in the case of the S_N2 mechanism, the leaving group may be positive or neutral and the base may be negatively charged or neutral.

Evidence for the existence of the E2 mechanism includes (1) the reaction displays the proper second-order kinetics; (2) when the hydrogen is replaced by deuterium in second-order eliminations, there is an isotope effect of from 3 to 8, consistent with breaking of this

bond in the rate-determining step.[7] However, neither of these results alone could prove an E2 mechanism, since both are compatible with other mechanisms also (e.g., see E1cB, Sec. 17.A.iii). The most compelling evidence for the E2 mechanism is found in stereochemical studies.[8]

As will be illustrated in the examples below, the E2 mechanism is stereospecific: The five atoms involved (including the base) in the transition state must be in one plane. There are two ways for this to happen. The H and X may be trans to one another (**A**) with a dihedral angle of 180°, or they may be cis (**B**) with a dihedral angle of 0°.[9] Conformation **A** is called *antiperiplanar*, and this type of elimination, in which H and X depart in opposite directions, is called *anti elimination*. Conformation **B** is *syn periplanar*, and this type of elimination, with H and X leaving in the same direction, is called *syn elimination*. Many examples of both kinds have been discovered. In the absence of special effects (discussed below), anti elimination is usually greatly favored over syn elimination, probably because **A** is a staggered conformation (Sec. 4.O.i) and the molecule requires less energy to reach this transition state than it does to reach the eclipsed transition state **B**. Solvent effects play an important role in the conformational preference. A few of the many known examples of predominant or exclusive anti elimination follow:

1. Elimination of HBr from *meso*-1,2-dibromo-1,2-diphenylethane gave *cis*-2-bromostilbene, while the (+) or (−) isomer gave the *trans*-alkene. This stereospecific result, which was obtained in 1904,[10] demonstrates that in this case elimination is anti. Many similar examples have been discovered since. Obviously, this type of experiment need not be restricted to compounds that have a meso form. Anti elimination requires that an erythro *dl* pair (or either isomer) give the cis alkene, and the threo *dl* pair (or either isomer) give the trans isomer. This result has been found many times. Anti elimination has also been demonstrated in cases where the electrofuge is not hydrogen. In the reaction of 2,3-dibromobutane with iodide

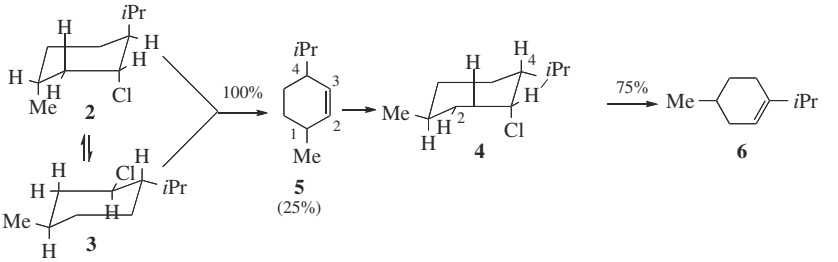
[10] Pfeiffer, P. *Z. Phys. Chem.* ***1904****, 48*, 40.

ion, the two bromines are removed (**17-22**). Using iodide as a base in this manner is unusual nowadays, and common bases are discussed in several sections below, including Reaction **17-13**. In this case, the meso compound gave the trans alkene while the *dl* pair gave the cis:[11]

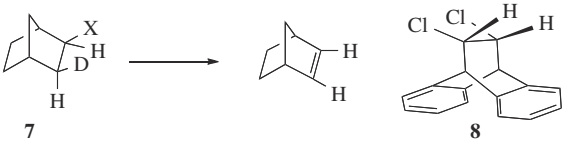


2. In open-chain compounds, rotation about C—C bonds usually lead to conformation in which H and X are antiperiplanar. However, in cyclic systems this is not always the case. There are nine stereoisomers of 1,2,3,4,5,6-hexachlorocyclohexane: seven meso forms and a *dl* pair (see Sec. 4.G). Four of the meso compounds and the *dl* pair) were treated with base to initiate elimination. Only one of these (**1**) has no Cl that is trans to an H. Of the other isomers, the fastest elimination rate was about three times as fast as the slowest, but the rate for **1** was 7000 times slower than that of the slowest of the other isomers.[12] This result demonstrates that anti elimination is greatly favored over syn elimination, although the latter must be taking place on **1**, but very slowly, to be sure.

1

3. The preceding result shows that elimination of HCl in a six-membered ring proceeds best when the H and X are trans to each other. Adjacent trans groups on a six-membered ring can be diaxial or diequatorial (Sec. 4.O.ii) and the molecule is generally free to adopt either conformation, although one may have a higher energy than the other. Antiperiplanarity of the leaving group and the proton on the adjacent carbon requires that they be diaxial, even if this is the conformation of higher energy. The results with menthyl and neomenthyl chlorides are easily interpretable on this basis. Menthyl chloride has two chair conformations, **2** and **3**. Compound **3**, in which the three substituents are all equatorial, is the more stable and less reactive. The more stable chair conformation of neomenthyl chloride is **4**, in which the chlorine is axial; there are axial hydrogen atoms on both C-2 and C-4. The results are the following: neomenthyl chloride gives rapid E2 elimination and the alkene produced is predominantly **6** (**6/5** ratio is ~ 3:1) in accord with *Zaitsev's rule* (see Reaction **12-2**, Sec. 17.B). Since an axial hydrogen is available on both sides, this factor does not control the direction of elimination and *Zaitsev's rule* is free to operate. However, for menthyl chloride, elimination is much slower and the product is entirely the *anti-Zaitsev* alkene **5**. It is slow because the unfavorable

[11] Winstein, S.; Pressman, D.; Young, W.G. *J. Am. Chem. Soc.* ***1939****, 61,* 1645.
[12] Cristol, S.J.; Hause, N.L.; Meek, J.S. *J. Am. Chem. Soc.* ***1951****, 73,* 674.

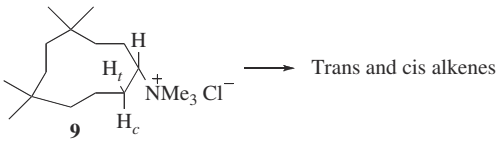


conformation (**2**) must be achieved before elimination can take place. There is an axial hydrogen only on this side as the product must be **5**.[13]

4. Anti elimination also occurs in the formation of triple bonds, as shown by elimination from *cis*- and *trans*-HO_2C-CH=C(Cl)CO_2H. In this case, the product in both cases is $HO_2CC{\equiv}CCO_2H$, but the trans isomer reacts $\sim$ 50 times faster than the cis compound.[14]

Some examples of syn elimination have been found in molecules where H and X could not achieve an antiperiplanar conformation.

1. The deuterated norbornyl bromide (**7**, X = Br) gave 94% of the product containing no deuterium.[15] Similar results were obtained with other leaving groups and with bicyclo [2.2.2] compounds.[16] In these cases the exo X group cannot achieve a dihedral angle of 180° with the endo β hydrogen because of the rigid structure of the molecule. The dihedral angle here is $\sim$ 120°. Syn elimination with a dihedral angle of $\sim$ 0° is clearly preferred to anti elimination where the angle is restricted to $\sim$ 120°.



2. Molecule **8** is a particularly graphic example of the need for a planar transition state. In **8**, each Cl has an adjacent hydrogen trans to it, and if planarity of leaving groups were not required, anti elimination could easily take place. However, the crowding of the rest of the molecule forces the dihedral angle to be $\sim$ 120°, and elimination of HCl from **8** is much slower than from corresponding nonbridged compounds.[17] Note that syn elimination from **8** is even less likely than anti elimination. Syn elimination can take place from the trans isomer of **8** (dihedral angle $\sim$ 0°); this isomer reacted about eight times faster than **8**.[17]

[15] Kwart, H.; Takeshita, T.; Nyce, J.L. *J. Am. Chem. Soc.* ***1964****, 86,* 2606.
[16] See Sicher, J.; Pánkova, M.; Závada, J.; Kniezo, L.; Orahovats, A. *Collect. Czech. Chem. Commun.* ***1971****, 36*, 3128; Bartsch, R.A.; Lee, J.G. *J. Org. Chem.* ***1991****, 56,* 212, 2579.
[17] Cristol, S.J.; Hause, N.L. *J. Am. Chem. Soc.* ***1952****, 74,* 2193.

The examples given so far illustrate two points. (1) Anti elimination *requires* a dihedral angle of 180°. When this angle cannot be achieved, anti elimination is greatly slowed or prevented entirely. (2) For the simple systems so far discussed, syn elimination is not found to any significant extent unless anti elimination is greatly diminished by failure to achieve the 180° angle.

The concept of vinylogy was introduced in Section 6.B and in Reaction **10-68**, category 4. Using this concept, a 1,2-elimination can be extended to give a 1,*x*-elimination when π bonds are incorporated between the carbon bearing the acidic proton and the leaving group (e.g., X-C-C=C-C, X-C-C=C-C=C-C or X-C-C≡C-C).[18]

As noted in Section 4.Q.ii, six-membered rings are the only ones among rings of 4–13 members in which strain-free antiperiplanar conformations can be achieved. It is not surprising, therefore, that syn elimination is least common in six-membered rings. Cycloalkyltrimethylammonium hydroxides were subjected to elimination (Reaction **17-7**) and the following percentages of syn elimination were found with each ring size: four-membered, 90%; five-membered, 46%; six-membered, 4% seven-membered, 31–37%.[19] Note that the NMe_3^+ group has a greater tendency to syn elimination than do other common leaving groups (e.g., OTs, Cl, and Br).

9

Other examples of syn elimination have been found in medium-ring compounds, where both cis and trans alkenes are possible (Sec. 4.K.i). As an illustration, elimination of 1,1,4,4-tetramethyl-7-cyclodecyltrimethylammonium chloride (**9**)[20] gave mostly *trans*- but also some *cis*-tetramethylcyclodecenes as products. Note that *trans*-cyclodecenes, although stable, are less stable than the cis isomers. In order to determine the stereochemistry of the reaction, the elimination was repeated, this time using deuterated substrates. When **9** was deuterated in the trans position ($H_t = D$), there was a substantial isotope effect in the formation of *both* cis and trans alkenes, but when **9** was deuterated in the cis position ($H_c = D$), there was *no* isotope effect in the formation of either alkene. Since an isotope effect is expected for an E2 mechanism,[21] these results indicated that *only* the trans hydrogen (H_t) was lost, whether the product was the cis or the trans isomer.[22] This in turn means that *the cis isomer must have been formed by anti elimination and the trans isomer by syn elimination*. Anti elimination could take place from approximately the conformation shown, but for syn elimination the molecule must twist into a conformation in which the C—H_t and C—NMe_3^+ bonds are syn periplanar. Other types of evidence have also demonstrated this remarkable result, called the syn–anti dichotomy.[23] The fact that syn

[21] Other possible mechanisms [e.g., E1cB, Sec. 17.A.iii or α′, β-elimination (Reaction **17-8**)], were ruled out in all these cases by other evidence.

[22] This conclusion has been challenged by Coke, J.L. *Sel. Org. Transform* ***1972****, 2*, 269.

[23] Sicher, J.; Závada, J. *Collect. Czech. Chem. Commun.* ***1967****, 32*, 2122; Závada, J.; Sicher, J. *Collect. Czech. Chem. Commun.* ***1967****, 32,* 3701. For a review, see Bartsch, R.A.; Závada, J. *Chem. Rev.* ***1980****, 80*, 453.

elimination in this case predominates over anti (as indicated by the formation of trans-isomer in greater amounts than cis) has been explained by conformational factors.[24] The syn–anti dichotomy has also been found in other medium-ring systems (8–12 membered),[25] although the effect is greatest for 10-membered rings. With leaving groups,[26] the extent of this behavior decreases in the order $^{+}NMe_3 > OTs > Br > Cl$, which parallels steric requirements. When the leaving group is uncharged, syn elimination is favored by strong bases and by weakly ionizing solvents.[27]

Syn elimination and the syn–anti dichotomy have also been found in open-chain systems, although to a lesser extent than in medium-ring compounds. For example, in the conversion of 3-hexyl-4-*d*-trimethylammonium ion to 3-hexene with potassium *sec*-butoxide, $\sim$ 67% of the reaction followed the syn-anti dichotomy.[28] In general, syn elimination in open-chain systems is only important in cases where certain types of steric effect are present. One such type is compounds in which substituents are found on both the β' and the γ carbons (the unprimed letter refers to the branch in which the elimination takes place). The factors that cause these results are not completely understood, but the following conformational effects have been proposed as a partial explanation.[29] The two anti- and two syn-periplanar conformations are, for a quaternary ammonium salt:

In order for an E2 mechanism to take place, a base must approach the proton marked $*$. In **C**, this proton is shielded on both sides by R and R′. In **D**, the shielding is on only one side. Therefore, when anti elimination does take place in such systems, it should give more cis product than trans. Also, when the normal anti elimination pathway is hindered sufficiently to allow the syn pathway to compete, the anti $\rightarrow$ trans route should be diminished more than the anti $\rightarrow$ cis route. When syn elimination begins to appear, it seems clear that **E**, which is less eclipsed than **F**, should be the favored pathway and syn elimination should generally give the trans-isomer. In general, deviations from the synanti dichotomy are greater on the trans side than on the cis. Thus, trans-alkenes are formed partly or mainly by syn elimination, but *cis*-alkenes are formed entirely by anti elimination.

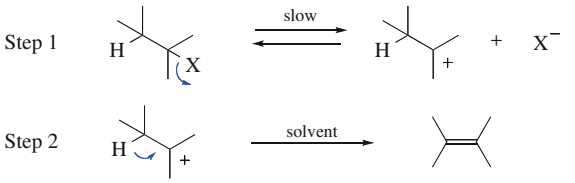
[29] Chiao, W.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* ***1977****, 99*, 6699.

Predominant syn elimination has also been found in compounds of the form $R^1R^2CHCHDNMe_3^+$, where R^1 and R^2 are both bulky.[30] In this case, the conformation leading to syn elimination (**H**) is also less strained than **G**, which gives anti elimination. The **G** compound has three bulky groups (including NMe_3^+) in the *gauche* position to each other.

It was mentioned above that weakly ionizing solvents promote syn elimination when the leaving group is uncharged. This is probably caused by ion pairing, which is greatest in nonpolar solvents.[31] Ion pairing can cause syn elimination with an uncharged leaving group by means of the transition state shown in **10**. This effect was graphically illustrated by elimination from 1,1,4,4-tetramethyl-7-cyclodecyl bromide.[32] The ratio of syn to anti elimination when this compound was treated with *t*-BuOK in the nonpolar benzene was 55.0. When the crown ether dicyclohexano-18-crown-6 was added (this compound selectively removes K^+ from the *t*-BuO^- K^{++} ion pair and thus leaves *t*-BuO^- as a free ion), the syn/anti ratio decreased to 0.12. Large decreases in the syn/anti ratio on addition of the crown ether were also found with the corresponding tosylate and with other nonpolar solvents.[33] However, with positively charged leaving groups the effect is reversed. Here, ion pairing *increases* the amount of anti elimination.[34] In this case, a relatively free base (e.g., PhO^-) can be attracted to the leaving group (see **11**), putting it in a favorable position for attack on the syn β hydrogen, while ion pairing would reduce this attraction.



It can be concluded that anti elimination is generally favored in the E2 mechanism, but that steric (inability to form the antiperiplanar transition state), conformational, ion pairing, and other factors cause syn elimination to intervene (and even predominate) in some cases.

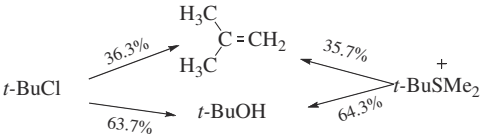
17.A.ii. The E1 Mechanism



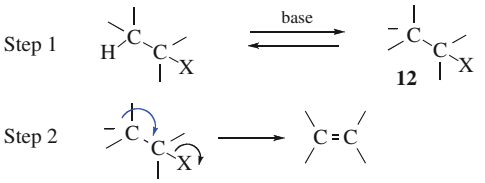
The E1 mechanism is a two-step process in which the rate-determining step is ionization of the substrate to give a carbocation that rapidly loses a β proton to a base, usually the solvent:

The IUPAC designation is $D_N + D_E$ (or $D_N + D_H$). This mechanism normally operates without an *added* base. Just as the E2 mechanism competes with the S_N2,[35] so the E1 mechanism competes with the S_N1. In fact, the first step of the E1 is exactly the same as that of the S_N1 mechanism. The second step differs in that the solvent pulls a proton from the β carbon of the carbocation rather than attacking it at the positively charged carbon, as in the S_N1 process. In a pure E1 reaction (without ion pairs, etc.), the product should be completely nonstereospecific, since bond rotation is possible in the carbocation before deprotonation.

Some of the evidence for the E1 mechanism is as follows:

1. The reaction exhibits first-order kinetics (in substrate) as expected. Of course, the solvent is not expected to appear in the rate equation, even if it were involved in the rate-determining step (Sec. 6.J.vi), but this point can be checked easily by adding a small amount of the conjugate base of the solvent. It is generally found that such an addition does not increase the rate of the reaction. If this more powerful base does not enter into the rate-determining step, it is unlikely that the solvent does. An example of an E1 mechanism with a rate-determining second step (proton transfer) has been reported.[36]
2. If the reaction is performed on two molecules that differ only in the leaving group (e.g., *t*-BuCl and *t*-$BuSMe_2^+$), the rates should obviously be different, since they depend on the ionizing ability of the molecule. However, once the carbocation is formed, if the solvent and the temperature are the same, it should suffer the same fate in both cases. This means that the nature of the leaving group does not affect the second step, and *the ratio of elimination to substitution should be the same*. The compounds mentioned in the example were solvolyzed at 65.3 °C in 80% aq ethanol with the following results:[37]

[35] See Villano, S.M.; Eyet, N.; Lineberger, W.C.; Bierbaum, V.M. *J. Am. Chem. Soc.* ***2009****, 131*, 8227.
[36] Baciocchi, E.; Clementi, S.; Sebastiani, G.V.; Ruzziconi, R. *J. Org. Chem.* ***1979****, 44,* 32.
[37] Cooper, K.A.; Hughes, E.D.; Ingold, C.K.; MacNulty, B.J. *J. Chem. Soc.* ***1948***, 2038.



Although the rates were greatly different (as expected with such different leaving groups), the product ratios were the same, within 1%. If this had taken place by a second-order mechanism, the nucleophile would not be expected to have the same ratio of preference for attack at the β hydrogen compared to attack at a *neutral* chloride as for attack at the β hydrogen compared to attack at a *positive* SMe_2 group.

3. Many reactions carried out under first-order conditions on systems where E2 elimination is anti proceed quite readily to give alkenes where a cis hydrogen must be removed, often in preference to the removal of a trans hydrogen. For example, menthyl chloride (**2**), which by the E2 mechanism gave only **5**, under E1 conditions gave 68% **6** and 32% **5**, since the steric nature of the hydrogen is no longer a factor here, and the more stable alkene (*Zaitsev's rule*, Reaction **12-2**) is predominantly formed.
4. If carbocations are intermediates, rearrangements should occur with suitable substrates. These have often been found in elimination reactions performed under E1 conditions.

E1 reactions can involve ion pairs, just as is true for S_N1 reactions (Sec. 10A. iii).[38] This effect is naturally greatest for nondissociating solvents: It is least in water, greater in ethanol, and greater still in acetic acid. It has been proposed that the ion-pair mechanism (Sec. 10.A.iii, category 1) extends to elimination reactions too, and that the S_N1, S_N2, E1, and E2 mechanisms possess in common an ion-pair intermediate, at least occasionally.[39]

17.A.iii. The E1cB Mechanism[40]

In the E1 mechanism, X leaves first and then H is removed. In the E2 mechanism, H is removed, which triggers the expulsion of X. There is a third possibility: The H is removed first to form **12**, and then X leaves. This reaction is a two-step process, called the E1cB *mechanism*,[41] or the *carbanion mechanism*, since the intermediate is a carbanion, (**12**). The

name E1cB comes from the fact that it is the conjugate base of the substrate that is giving up the leaving group (see the S_N1cB mechanism, Sec. 10.G.iii, category 1). The IUPAC designation is $A_nD_E + D_N$ or $A_{xh}D_H + D_N$ (see Sec. 9.F). Three limiting cases can be distinguished: (1) The carbanion returns to starting material faster than it forms product: step 1 is reversible; step 2 is slow. (2) Step 1 is the slow step, and formation of product is faster than return of the carbanion to starting material. In this case, step 1 is essentially

[38] See Thibblin, A. *J. Am. Chem. Soc.* ***1987****, 109,* 2071; *J. Phys. Org. Chem.* ***1989****, 2*, 15.

[41] See Ryberg, P.; Matsson, O. *J. Org. Chem.* ***2002****, 67*, 811.

irreversible. (3) Step 1 is rapid, and the carbanion goes slowly to product. This case occurs only with the most stable carbanions. Here, too, step 1 is essentially irreversible. These cases have been given the designations: (1) $(E1cB)_R$, (2) $(E1cB)_I$ (or $E1cB_{irr}$), and (3) $(E1)_{anion}$. Their characteristics are listed in Table 17.1.[42] Investigations of the reaction order are generally not very useful (except for case 3, which is first order), because cases 1 and 2 are second order and thus difficult or impossible to distinguish from the E2 mechanism by this procedure.[43] The greatest likelihood of finding the E1cB mechanism is expected in substrates that have (a) a poor nucleofuge and (b) an acidic hydrogen. In addition, most investigations have concerned such substrates. The following is some of the evidence in support of the E1cB mechanism:

1. The first step of the $(E1cB)_R$ mechanism involves a reversible exchange of protons between the substrate and the base. In that case, if deuterium is present in the base, recovered starting material should contain deuterium. This was found to be the case in the treatment of $Cl_2C{=}CHCl$ with NaOD to give $ClC{\equiv}CCl$. When the reaction was stopped before completion, there *was* deuterium in the recovered alkene.[44] A similar result was found for pentahaloethanes.[45] These substrates are relatively acidic. In both cases, the electron-withdrawing halogens increase the acidity of the hydrogen, and in the case of trichloroethylene there is the additional factor that a hydrogen on an sp^2 carbon is more acidic than one on an sp^3 carbon (Sec. 8.F, category 7). Thus, the E1cB mechanism is more likely to be found in eliminations yielding triple bonds than in those giving double bonds. Another likely place for the E1cB mechanism should be in reaction of a substrate like $PhCH_2CH_2Br$, since the carbanion is stabilized by resonance with the phenyl group. Nevertheless, no deuterium exchange was found here.[46] If this type of evidence is a guide, then it may be inferred that the $(E1cB)_R$ mechanism is quite rare, at least for eliminations with common leaving groups (e.g., Br, Cl, or OTs), which yield C=C double bonds.
2. When the reaction shown was carried out in water containing acetohydroxamate buffers, a plot of the rate against the buffer concentration was curved and the rate leveled off at high buffer concentrations, indicating a change in rate-determining step.[47] This rules out an E2 mechanism, which has only one step.[48] When D_2O was used instead of H_2O as solvent, there was an initial inverse solvent isotope effect of 7.7 (the highest inverse solvent isotope effect yet reported).

$$p\text{-}NO_2C_6H_4{-}CH_2{-}CH_2{-}\overset{+}{N}R_4 + B^- \rightarrow p\text{-}NO_2C_6H_4{-}CH_2{=}CH_2 + BH + NR_3$$

[42] This table, which appears in Cockerill, A.F.; Harrison, R.G. in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics,* Vol. 9, Elsevier, NY, ***1973***, p. 161, was adapted from a longer one in Bordwell, F.G. *Acc. Chem. Res.* ***1972****, 5,* 374, see p. 375.

[43] The $(E1cB)_I$ mechanism cannot be distinguished from E2 by this means, because it has the identical rate law: Rate $= k$[substrate][B^-]. The rate law for $(E1cB)_R$ is different: Rate $= k$[substrate][B^-]/[BH], but this is often not useful because the only difference is that the rate is also dependent (inversely) on the concentration of the conjugate acid of the base, and this is usually the solvent, so that changes in its concentration cannot be measured.

That is, the reaction took place faster in D_2O than in H_2O. This is compatible only with an E1cB mechanism in which the proton-transfer step is not entirely rate determining. The isotope effect arises from a partitioning of the carbanion intermediate (**12**). This intermediate either can go to product or it can revert to starting compound, which requires taking a proton from the solvent. In D_2O, the latter process is slower (because the O—D bond of D_2O, cleaves less easily than the O—H bond of H_2O), reducing the rate at which **12** returns to starting compound. With the return reaction competing less effectively, the rate of conversion of **12** to product is increased.

3. Substrates containing acidic hydrogen atoms and poor leaving groups are most likely to proceed by the E1cB mechanism. Compounds of the type ZCH_2CH_2OPh, where Z is an electron-withdrawing group (e.g., NO_2, SMe_2^+, $ArSO_2$, CN, CO_2R), belong to this category, because OPh is a very poor leaving group (Sec. 10.A.iii, category 1). There is much evidence to show that the mechanism here is indeed E1cB.[49] Isotope effects, measured for $MeSOCD_2CH_2OPh$ and $Me_2S^+CD_2CH_2OPh$ with NaOD in D_2O, are ~ 0.7. This is compatible with an $(E1cB)_R$ mechanism, but not with an E2 mechanism for which an isotope effect of perhaps 5 might be expected (of course, an E1 mechanism is precluded by the extremely poor nucleofugal ability of OPh). The fact that k_H/k_D is less than the expected value of 1 is attributable to solvent and secondary isotope effects. Among other evidence for an E1cB mechanism in these systems is that changes in the identity of Z had a dramatic effect on the relative rates: a span of 10^{11} between NO_2 and COO^-. Note that elimination from substrates of the type $RCOCH_2CH_2Y$ is the reverse of *Michael-type addition* to C=C bonds. Such addition involves initial attack by a nucleophile Y and subsequent protonation (see Sec. 15.A.ii). Thus the initial loss of a proton from substrates of this type (i.e., an E1cB mechanism) is in accord with the principle of microscopic reversibility.[50] It may also be recalled that benzyne formation (Sec. 13.A.iii) can occur by such a process. It has been suggested that all base-initiated eliminations wherein the proton is activated by a strong electron-withdrawing group are E1cB reactions,[51] but there is evidence that this is not the case when there is a good nucleofuge, the mechanism is E2 even when strong electron-withdrawing groups are present.[52] On the other hand, Cl^- has been found to be a leaving group in an E1cB reaction.[53]

   Of the three cases of the E1cB mechanism, the one most difficult to distinguish from E2 is $(E1cB)_I$. One way to make this distinction is to study the effect of a change in leaving group. This was done in the case of the three acenaphthylenes (**13**), where it was found that (1) the three rates were fairly similar, the largest being

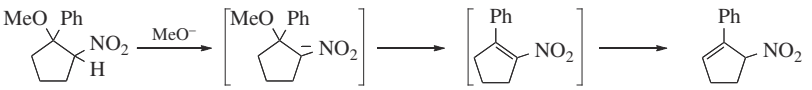
only about four times that of the smallest, and (2) in compound c (X = Cl, Y = F), the only product contained Cl and no F (i.e., only the poorer nucleofuge F departed



13

while Cl remained).[54] Result (1) rules out all the E1cB mechanisms except $(E1cB)_I$, because the others should all have considerable leaving group effects (Table 17.1). An ordinary E2 mechanism should also have a large leaving-group effect, but an E2 mechanism with substantial carbanionic character (see Section 17.A.iv) might not. However, no E2 mechanism can explain result (2), which can be explained by the fact that an α Cl is more effective than an α F in stabilizing the planar carbanion that remains when the proton is lost. Thus (as in the somewhat similar case of aromatic nucleophilic substitution, see Sec. 13.B.ii), when X^- leaves in the second step, the one that leaves is not determined by which is the better nucleofuge, but by which has had its β hydrogen removed.[55] Additional evidence for the existence of the $(E1cB)_I$ mechanism was the observation of a change in the rate-determining step in the elimination reaction of *N*-(2-cyanoethyl)pyridinium ions (**14**), treated with base, when X was changed.[56] Once again, the demonstration that two steps are involved precludes the one-step E2 mechanism. Note that pyridyl systems appear to be a borderline case, and it is not obvious if the reaction involves a carbanion intermediate (E1cb, $A_{xh}D_H + D_N$) or if the reaction proceeds by concerted loss of a proton and the halide (E2, $A_ND_ED_N$) with attack by the base.[57]

14

4. An example of an $(E1)_{anion}$ mechanism has been found with the substrate **15**, which when treated with methoxide ion undergoes elimination to **17**, which is unstable under the reaction conditions and rearranges as shown.[58] Among the evidence for the proposed mechanism in this case were kinetic and isotope-effect results, as well as the spectral detection of **16**.[59]

5. In many eliminations to form C=O and C≡N bonds, the initial step is loss of a positive group (normally a proton) from the oxygen or nitrogen. These may also be regarded as E1cB processes.

There is evidence that some E1cB mechanisms can involve carbanion ion pairs, for example,[60]

This case is designated $(E1cB)_{ip}$; its characteristics are shown in Table 17.1.

17.A.iv. The E1–E2–E1cB Spectrum

In the three mechanisms so far considered, the similarities are greater than the differences. In each case, there is a leaving group that comes off with its pair of electrons and another group (usually hydrogen) that comes off without them. The only difference is in the order of the steps. It is now generally accepted that there is a spectrum of mechanisms ranging from one extreme, in which the leaving group departs well before the proton (pure E1), to the other extreme, in which the proton is removed first and then, after some time, the leaving group follows (pure E1cB). The *pure* E2 case would be somewhere in the middle, with both groups leaving simultaneously. However, most E2 reactions are not exactly in the middle, but somewhere to one side or the other. For example, the nucleofuge might depart just before the proton. This case may be described as an E2 reaction with a small amount of E1 character. The concept can be expressed by the question: In the transition state, which bond (C—H or C—X) has undergone more cleavage?[61]

Note that in both E1 and E2 reactions, removal of the hydrogen atom is an acid–base reaction, requiring a base. A stronger base is required for the E2, and a weaker base for E1. Further, the E1 reaction requires a solvent that facilitates ionization to a carbocation (e.g., aqueous media), whereas the E2 reaction is usually done in a protic solvent (e.g., an alcohol).

One way to determine just where a given reaction stands on the E1–E2–E1cB spectrum is to study isotope effects, which ought to tell something about the behavior of bonds in the transition state.[62] For example, $CH_3CH_2NMe_3^+$ showed a nitrogen isotope effect (k^{14}/k^{15}) of 1.017, while $PhCH_2CH_2NMe_3^+$ gave a corresponding value of 1.009.[63] It would be expected that the phenyl group would move the reaction toward the E1cB side of the line, which means that for this compound the C—N bond is not as greatly broken in the

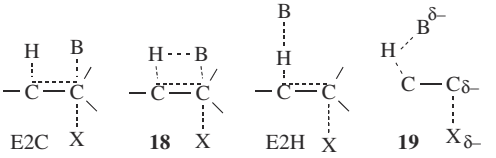
transition state as it is for the unsubstituted one. The isotope effect bears this out, for it shows that in the phenyl compound, the mass of the nitrogen has less effect on the reaction rate than it does in the unsubstituted compound. Similar results have been obtained with SR_2^+ leaving groups by the use of $^{32}S/^{34}S$ isotope effects[64] and with Cl ($^{35}Cl/^{37}Cl$).[65] The position of reactions along the spectrum has also been studied from the other side of the newly forming double bond by the use of H/D and H/T isotope effects,[66] although interpretation of these results is clouded by the fact that β hydrogen isotope effects are expected to change smoothly from small to large to small again as the degree of transfer of the β hydrogen from the β carbon to the base increases[67] (in Sec. 6.B, it was noted that isotope effects are greatest when the proton is half-transferred in the transition state), by the possibility of secondary isotope effects (e.g., the presence of a β deuterium or tritium may cause the leaving group to depart more slowly), and by the possibility of tunneling.[68] Other isotope-effect studies have involved labeled α or β carbon, labeled α hydrogen, or labeled base.[58]

Another way to study the position of a given reaction on the spectrum involves the use of β aryl substitution. Since a positive *Hammet ρ value* is an indication of a negatively charged transition state, the ρ value for substituted β aryl groups should increase as a reaction moves from E1-to-E1cB-like along the spectrum. This has been shown to be the case in a number of studies;[69] for example, ρ values of $ArCH_2CH_2X$ increase as the leaving-group ability of X decreases. A typical set of ρ values was X = I, 2.07; Br, 2.14; Cl, 2.61; SMe_2^+, 2.75; F, 3.12.[70] As seen previously, decreasing leaving-group ability correlates with increasing E1cB character.



Still another method measures volumes of activation.[71] These are negative for E2 and positive for E1cB mechanisms. Measurement of the activation volume therefore provides a continuous scale for deciding just where a reaction lies on the spectrum.

17.A.v. The E2C Mechanism[72]

Certain alkyl halides and tosylates undergo E2 eliminations faster when treated with such weak bases as Cl^- in polar aprotic solvents or PhS^- than with the usual E2 strong bases (e.g., RO^- in ROH).[73] In order to explain these results, it was proposed[74] that there is a spectrum[75] of E2 transition states in which the base can interact in the transition state with the α carbon, as well as with the β hydrogen. At one end of this spectrum is a mechanism (called E2C) in which, in the transition state, the base interacts mainly with the carbon. The

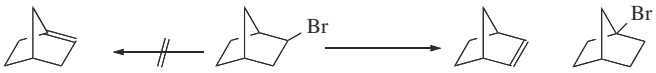
[75] This is apart from the E1-E2-E1cB spectrum.

E2C mechanism is characterized by strong nucleophiles that are weak bases. At the other extreme is the normal E2 mechanism, here called E2H to distinguish it from E2C, characterized by strong bases. Transition state **18** represents a transition state between these extremes. Additional evidence[76] for the E2C mechanism is derived from *Brønsted equation* considerations (Sec. 8.D), from substrate effects, from isotope effects, and from the effects of solvents on rates.

However, the E2C mechanism has been criticized, and it has been contended that all the experimental results can be explained by the normal E2 mechanism.[77] McLennan and Lim[78] suggested that the transition state is that shown as **19**. An ion-pair mechanism has also been proposed.[79] Although the actual mechanisms involved may be a matter of controversy, there is no doubt that a class of elimination reactions exists that is characterized by second-order attack by weak bases.[80] These reactions also have the following general characteristics:[81] (1) they are favored by good leaving groups; (2) they are favored by polar aprotic solvents; (3) the reactivity order is tertiary > secondary > primary, the opposite of the normal E2 order (Sec. 17.D.i); (4) the elimination is always anti (syn elimination is not found), but in cyclohexyl systems, a diequatorial anti elimination is about as favorable as a diaxial anti elimination (unlike the normal E2 reaction, Sec. 17.A.i, categories 2,3); (5) they follow *Zaitsev's rule* (see below), where this does not conflict with the requirement for anti elimination.



17.B. REGIOCHEMISTRY OF THE DOUBLE BOND

With some substrates, a β hydrogen is present on only one carbon and (barring rearrangements) there is no doubt as to the identity of the product. For example, $PhCH_2CH_2Br$ can give only $PhCH{=}CH_2$. However, in many other cases two or three alkenyl products are possible. In the simplest such case, a *sec*-butyl compound can give either 1- or 2-butene. There are a number of rules that enable a prediction, in many instances, of which product will predominantly form.[82]

1. No matter the mechanism, a double bond does not go to a bridgehead carbon unless the ring sizes are large enough (*Bredt's rule*, see Sec. 4.P.iii). This means, for

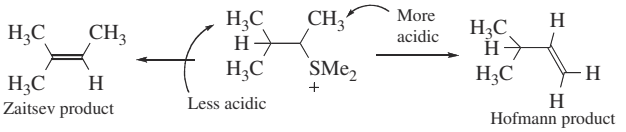
example, not only that **20** gives only **21** and not **22** (indeed **22** is not a known compound), but also that **23** does *not* undergo elimination.



22 **20** **21** **23**

2. No matter the mechanism, if there is a double bond (C=C or C=O) or an aromatic ring already in the molecule that can be in conjugation with the new double bond, the conjugated product usually predominates, sometimes even when the stereochemistry is unfavorable (for an exception, see Sec. 17.C).
3. In the E1 mechanism, the leaving group is gone before the choice is made as to which direction the new double bond takes. Therefore the direction is determined almost entirely by the relative stabilities of the two (or three) possible alkenes. In such cases, *Zaitsev's rule*[83] operates. This rule states that *the double bond goes mainly toward the most highly substituted carbon*. That is, 3-bromo-2,3-dimethylpentane gives more 2,3-dimethyl-2-pentene than either 3,4-dimethyl-2-pentene or 2-ethyl-3-methyl-1-butene. Thus *Zaitsev's rule* predicts that the alkene predominantly formed will be the one with the largest possible number of alkyl groups on the C=C carbons, and in most cases this is what is found. From heat of combustion data (see Sec. 1.L), it is known that alkene stability increases with alkyl substitution, although just why this should be is a matter of conjecture. The most common explanation is hyperconjugation. For E1 eliminations, *Zaitsev's rule* governs the orientation whether the leaving group is neutral or positive, since, as already mentioned, the leaving group is not present when the choice of direction is made. This statement does not hold for E2 eliminations, and it may be mentioned here, for contrast with later results, that E1 elimination of $Me_2CHCHMeSMe_2^+$ gave 91% of the *Zaitsev* product and 9% of the other.[84] However, there *are* cases in which the leaving group affects the direction of the double bond in E1 eliminations.[85] This may be attributed to ion pairs; that is, the leaving group is not completely gone when the hydrogen departs. *Zaitsev's rule* breaks down in cases where the non-*Zaitsev* product is more stable for steric reasons. For example, E1 or E1-like eliminations of 1,2-diphenyl-2-X-propanes ($PhMeCXCH_2Ph$) were reported to give $\sim$ 50% $CH_2{=}CPhCH_2Ph$, despite the fact that the double bond of the *Zaitsev* product (PhMeC=CHPh) is conjugated with two benzene rings.[86]
4. For the anti E2 mechanism, a trans β proton is necessary; if this is available in only one direction, that is the way the double bond will form. Because of the free rotation in acyclic systems (except where steric hindrance is great), this is a factor only in cyclic systems. Where trans β hydrogen atoms are available on two or three carbons, two types of behavior are found, depending on substrate structure and the nature of the leaving group. Some compounds follow *Zaitsev's rule* and give predominant formation of the most highly substituted alkene, but others follow *Hofmann's rule: The double bond goes mainly toward the least highly substituted carbon*. Although many exceptions are known, the following general statements can be made: In most

[83] Often given the German spelling: Saytzeff, or Saytseff, or Saytzev.

cases, compounds containing uncharged nucleofuges (those that come off as negative ions) follow *Zaitsev's rule*, just as they do in E1 elimination, no matter what the structure of the substrate. However, elimination from compounds with charged nucleofuges (e.g., NR_3^+, SR_2^+, those that come off as neutral molecules), follow *Hofmann's rule* if the substrate is acyclic,[87] but *Zaitsev's rule* if the leaving group is attached to a six-membered ring.[88]

Much work has been devoted to searching for reasons for the differences in orientation. Since *Zaitsev* orientation almost always gives the thermodynamically more stable isomer, are must explain why in some cases the less stable *Hofmann* product predominates. Three explanations have been offered for the change in orientation in acyclic systems with a change from uncharged to charged nucleofuges. The first of these[89] is that *Hofmann orientation* is caused by the fact that the acidity of the β hydrogen is decreased by the presence of the electron-donating alkyl groups. For example, under E2 conditions $Me_2CHCHMeSMe_2^+$ gives more of the

Hofmann product; it is the more acidic hydrogen that is removed by the base. Of course, the CH_3 hydrogen atoms would still be more acidic than the Me_2CH hydrogen even if a neutral leaving group were present, but the explanation presented was that acidity matters with charged and not with neutral leaving groups, because the charged groups exert a strong electron-withdrawing effect, making differences in acidity greater than they are with the less electron-withdrawing neutral groups.[85,90] According to this, the change to a positive leaving group causes the mechanism to shift toward the E1cB end of the spectrum, where there is more C—H bond breaking in the rate-determining step and where, consequently, acidity is more important. In this view, when there is a neutral leaving group, the mechanism is more E1-like, C—X bond breaking is more important, and alkene stability determines the direction of the new double bond.

The third explanation is completely different: Field effects are unimportant, and the difference in orientation is largely a steric effect caused by the fact that charged groups are usually larger than neutral ones. A CH_3 group is more open to attack than a CH_2R group and a CHR_2 group is still less easily attacked. Of course, these considerations also apply when the leaving group is neutral, but they are proposed to be much less important here because the neutral groups are smaller and do not block access to the hydrogen atoms as much. Experiments showed that *Hofmann elimination* increases with the size of the leaving group. Thus the percentage of 1-ene obtained from $CH_3CH_2CH_2CHXCH_3$ was as follows (X listed in order of

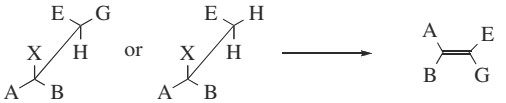
increasing size): Br, 31%; I, 30%; OTs, 48%; SMe_2^+, 87%; SO_2Me, 89%; NMe_3^+, 98%.[91] *Hofmann elimination* was also shown to increase with increase in bulk of the substrate.[92] With large enough compounds, *Hofmann orientation* can be obtained even with halides. *tert*-Amyl bromide gave 89% of the *Hofmann* product, for example. Even those who believe in the acidity explanations concede that these steric factors operate in extreme cases.[93]

There is one series of results incompatible with the steric explanation that E2 elimination from the four 2-halopentanes gave the following percentages of 1-pentene: F, 83%; Cl, 37%; Br, 25%; I, 20%.[94] The same order was found for the four 2-halohexanes.[95] Although there is some doubt about the relative steric requirements of Br, Cl, and I, there is no doubt that F is the smallest of the halogens, and if the steric explanation were the only valid one, the fluoroalkanes could not give predominant *Hofmann orientation*. Another result that argues against the steric explanation is the effect of changing the nature of the base. An experiment in which the effective size of the base was kept constant while its basicity was increased (by using as bases a series of $XC_6H_4O^-$ ions) showed that the percentage of *Hofmann elimination* increased with increasing base strength, although the size of the base did not change.[96] These results are in accord with the previous explanation, since an increase in base strength moves an E2 reaction closer to the E1cB end of the spectrum. In further experiments, a large series of bases of different kinds was shown to obey linear free energy relationships between basicity and percentage of *Hofmann elimination*.[97] Certain very large bases (e.g., 2,6-di-*tert*-butyl-phenoxide) did not obey the relationships and steric effects are important in these cases. How large the base must be before steric effects are observed depends on the pattern of alkyl substitution in the substrate, but not on the nucleofuge.[98] One further result may be noted. In the gas phase, elimination of H and BrH^+ or H and ClH^+ using Me_3N as the base predominantly followed *Hofmann's rule*,[99] although BrH^+ and ClH^+ are not very large.



5. Only a few investigations on the orientation of syn E2 eliminations have been carried out, but these show that *Hofmann orientation* is greatly favored over *Zaitsev*.[100]
6. In the E1cB mechanism, the question of orientation seldom arises because the mechanism is generally found only where there is an electron-withdrawing group in the β position, and that is where the double bond goes.

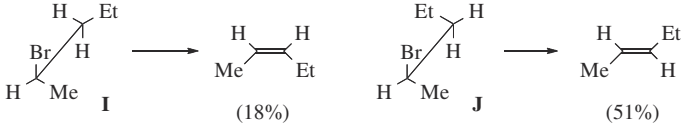
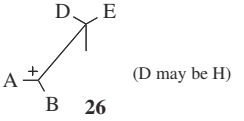
7. As already mentioned, E2C reactions show a strong preference for Zaitsev orientation.[101] In some cases, this can be put to preparative use. For example, the compound $PhCH_2CHOTsCHMe_2$ gave ~ 98% $PhCH{=}CHCHMe_2$ under the usual E2 reaction conditions (*t*-BuOK in *t*-BuOH). In this case, the double bond goes to the side with more hydrogen atoms because on that side it will be able to conjugate with the benzene ring. However, with the weak base $Bu_4N^+ Br^-$ in acetone the *Zaitsev* product ($PhCH_2CH{=}CMe_2$) was formed in 90% yield.[102]



17.C. STEREOCHEMISTRY OF THE DOUBLE BOND

When elimination takes place on a compound of the form CH_3—CABX or CHAB—CGGX, the new alkene does not have cis–trans isomerism, but for compounds of the form CHEG—CABX (E and G *not* H) (**24**) and CH_2E—CABX (**25**), cis and trans isomers are possible. When the anti E2 mechanism is in operation, **24** gives the isomer



24 **25**

arising from trans orientation of X and H. As seen previously (Sec. 17.A.i), an erythro compound gives the cis alkene and a threo compound gives the trans. For **25**, two conformations are possible for the transition state; these lead to different isomers and often both are obtained. However, the one that predominates is often determined by an eclipsing effect.[103] For example, *Zaitsev elimination* from 2-bromopentane can occur as follows: In conformation **I**, the ethyl group is between Br and Me, while in **J** it is between Br and H. This means that **J** is more stable, and most of the elimination should occur from this conformation. This is indeed what happens, and 51% of the trans isomer is formed (with KOEt) compared to 18% of the cis (the rest is the *Hofmann* product).[104] These effects become larger with increasing size of groups A, B, and E.

I (18%) **J** (51%)

However, eclipsing effects are not the only factors that affect the cis/trans ratio in anti E2 eliminations. Other factors are the nature of the leaving group, the base, the solvent, and the substrate. Not all of these effects are completely understood.[105]

For E1 eliminations, if there is a free carbocation (**26**), it is free to rotate, and no matter the geometry of the original compound, the more stable situation is the one where the larger of the D–E pair is opposite the smaller of the A—B pair and the corresponding alkene should form. If the carbocation is not completely free, then to that extent, E2-type products are formed. Similar considerations apply in E1cB eliminations.[106]

17.D. REACTIVITY

In this section, we examine the effects of changes in the substrate, base, leaving group, and medium on (1) overall reactivity, (2) E1 versus E2 versus E1cB,[107] and (3) elimination versus substitution.

17.D.i. Effect of Substrate Structure

1. *Effect on Reactivity.* The carbon containing the nucleofuge (X) is referred to as the α carbon and the carbon that loses the positive species (usually a proton) as the β carbon. Groups attached to the α or β carbons can exert at least four kinds of influence:
   a. They can stabilize or destabilize the incipient double bond (both α and β groups).
   b. They can stabilize or destabilize an incipient negative charge, affecting the acidity of the proton (β groups only).
   c. They can stabilize or destabilize an incipient positive charge (α groups only).
   d. They can exert steric effects (e.g., eclipsing effects) (both α and β groups).

   Effects *a* and *d* can apply in all three mechanisms, although steric effects are greatest for the E2 mechanism. Effect *b* does not apply in the E1 mechanism, and effect *c* does not apply in the E1cB mechanism. Groups such as Ar and C=C increase the rate by any mechanism, except perhaps when formation of the C=C bond is not the rate-determining step, whether they are α or β (effect a). Electron-withdrawing groups increase the acidity when in the β position, but have little effect in the a position unless they also conjugate with the double bond. Thus Br, Cl, CN, Ts, NO_2, CN, and SR in the β position all increase the rate of E2 eliminations.
2. *Effect on E1 versus E2 versus E1cB.* The α alkyl and α aryl groups stabilize the carbocation character of the transition state, shifting the spectrum toward the E1 end. β Alkyl groups also shift the mechanism toward E1, since they *decrease* the acidity of the hydrogen. However, β aryl groups shift the mechanism the other way (toward E1cB) by stabilizing the carbanion. Indeed, as seen in Section 17.A.iii, all electron-withdrawing groups in the β position shift the mechanism toward E1cB.[108] α alkyl groups also increase the extent of elimination with weak bases (E2C reactions).

TABLE 17.2 The Effect of α and β Branching on the Rate of E2 Elimination and the Amount of Alkene Formed[a]

Substrate	Temperature (°C)	Alkene (%)	Rate $\times 10^5$ of E2 reaction	Reference
CH_3CH_2Br	55	0.9	1.6	109
$(CH_3)_2CHBr$	24	80.3	0.237	110
$(CH_3)_3Br$	25	97	4.17	111
$CH_3CH_2CH_2Br$	55	8.9	5.3	109
$(CH_3)_2CHCH_2Br$	55	59.5	8.5	109

[a]The reactions were between the alkyl bromide and $^-$OEt. The rate for isopropyl bromide was actually greater than that for ethyl bromide, if the temperature difference is considered. Neopentyl bromide, the next compound in the β-branching series, cannot be compared because it has no β hydrogen and cannot give an elimination product without rearrangement.

3. *Effect on Elimination versus Substitution.* Under second-order conditions, increased branching increases elimination, to the point where tertiary substrates undergo few S_N2 reactions, as seen in Chapter 10. For example, Table 17.2 shows results on some simple alkyl bromides. Similar results were obtained with SMe_2^+ as the leaving group.[111] Two reasons can be presented for this trend. One is statistical: As α branching increases, there are usually more hydrogen atoms for the base to attack. The other is that α branching presents steric hindrance to attack of the base at the carbon. Under first-order conditions, increased α branching also increases the amount of elimination (E1 vs S_N1), although not so much, and usually the substitution product predominates. For example, solvolysis of *tert*-butyl bromide gave only 19% elimination[112] (cf. with Table 17.2). β Branching also increases the amount of E2 elimination with respect to S_N2 substitution (Table 17.2), not because elimination is faster, but because the S_N2 mechanism is so greatly slowed (Sec. 10.G. i). Under first-order conditions too, β branching favors elimination over substitution, probably for steric reasons.[113] However, E2 eliminations from compounds with charged leaving groups are slowed by β branching. This is related to *Hofmann's rule* (Sec. 17.B, category 4). Electron-withdrawing groups in the β position not only increase the rate of E2 eliminations and shift the mechanisms toward the E1cB end of the spectrum, but also increase the extent of elimination as opposed to substitution.

   Another method that compares E2 and S_N2 reactions is called the *activation-strain model*. In this model, the activation energy = activation strain + transition state interaction, and corresponds directly to the strength of the Lewis acid or base. A more basic nucleophile or base, with a higher energy HOMO, and a more acidic substrate, with a lower energy LUMO, interact more strongly.[114] Activation strain is connected with the strength of the bonds broken: A strong C-leaving group bond has a higher activation strain and a higher barrier. Using this model, the E2 reaction has

[109] Hughes, E.D.; Ingold, C.K.; Maw, G.A. *J. Chem. Soc.* ***1948***, 2072; Hughes, E.D.; Ingold, C.K.; Woolf, L.I. *J. Chem. Soc.* ***1948***, 2084.

a higher activation strain than S_N2 because two bonds are broken, and with weak bases, S_N2 dominates E2 because S_N2 has less activation strain.[115] With strong bases, a favorable interaction of the more acidic transition state for the E2 reaction leads to a preference for E2.

17.D.ii. Effect of the Attacking Base

1. *Effect on E1 versus E2 versus E1cB.* In the E1 mechanism, an external base is generally not required: The solvent acts as the base. Hence, when external bases are added, the mechanism is shifted toward E2. Stronger bases and higher base concentrations cause the mechanism to move toward the E1cB end of the E1–E2–E1cB spectrum.[116] However, weak bases in polar aprotic solvents can also be effective in elimination reactions with certain substrates (the E2C reaction). Normal E2 elimination has been accomplished with the following bases:[117] H_2O, NR_3, ^-OH, ^-OAc, ^-OR, ^-OAr, $^-NH_2$, CO_3^{2-}, $LiAlH_4$, I^-, ^-CN, and organic bases. However, the only bases of preparative importance in the normal E2 reaction are ^-OH, ^-OR, and $^-NH_2$, usually in the conjugate acid as solvent, and certain amines. Weak bases effective in the E2C reaction are Cl^-, Br^- F^-, ^-OAc, and RS^-. These bases are often used in the form of their R_4N^+ salts.
2. *Effect on Elimination versus Substitution.* Strong bases not only benefit E2 as against E1, but also benefit elimination as against substitution. With a high concentration of strong base in a nonionizing solvent, bimolecular mechanisms are favored and E2 predominates over S_N2. At low-base concentrations, or in the absence of base altogether, in ionizing solvents, unimolecular mechanisms are favored, and the S_N1 mechanism predominates over the E1. Chapter 10 pointed out that some species are strong nucleophiles but weak bases (Sec. 10.G.ii). The use of these obviously favors substitution, except that, as seen, elimination can predominate if polar aprotic solvents are used. It has been shown for the base cyanide that in polar aprotic solvents, the less the base is encumbered by its counterion in an ion pair (i.e., the freer the base), the more substitution is favored at the expense of elimination.[118]

17.D.iii. Effect of the Leaving Group

1. *Effect on Reactivity.* The leaving groups in elimination reactions are similar to those in nucleophilic substitution. The E2 eliminations have been performed with the following groups: $^+NR_3$, $^+PR_3$, $^+SR_2$, ^+OHR, SO_2R, OSO_2R, OCOR, OOH, OOR, NO_2,[119] F, Cl, Br, I, and CN (*not*$^+$ OH_2). The E1 eliminations have been

carried out with: $^{+}NR_3$, $^{+}SR_2$, $^{+}OH_2$, ^{+}OHR, OSO_2R, OCOR, Cl, Br, I, and $^{+}N_2$.[120] However, the major leaving groups for preparative purposes are $^{+}OH_2$ (always by E1) and Cl, Br, I, and $^{+}NR_3$ (usually by E2).

2. *Effect on E1 versus E2 versus E1cB.* Better leaving groups shift the mechanism toward the E1 end of the spectrum, *since they make ionization easier*. This effect has been studied in various ways. One way already mentioned was a study of ρ values (Sec. 17.A.iv). Poor leaving groups and positively charged leaving groups shift the mechanism toward the E1cB end of the spectrum because the strong electron-withdrawing field effects increase the acidity of the β hydrogen.[121] The E2C reaction is favored by good leaving groups.
3. *Effect on Elimination versus Substitution.* As seen previously (Sec. 17.A.ii), for first-order reactions the leaving group has nothing to do with the competition between elimination and substitution, since it is gone before the decision is made as to which path to take. However, where ion pairs are involved, this is not true, and results have been found where the nature of the leaving group does affect the product.[122] In second-order reactions, the elimination/substitution ratio is not greatly dependent on a halide leaving group, although there is a slight increase in elimination in the order I > Br > Cl. When OTs is the leaving group, there is usually much more substitution. For example, *n*-$C_{18}H_{37}$Br treated with *t*-BuOK gave 85% elimination, while *n*-$C_{18}H_{37}$OTs gave, under the same conditions, 99% substitution.[123] On the other hand, positively charged leaving groups increase the amount of elimination.

17.D.iv. Effect of the Medium

1. *Effect of Solvent on E1 versus E2 versus E1cB.* With any reaction a more polar environment enhances the rate of mechanisms that involve ionic intermediates. For neutral leaving groups, it is expected that E1 and E1cB mechanisms will be aided by increasing the polarity of the solvent and by increasing the ionic strength. With certain substrates, polar aprotic solvents promote elimination with weak bases (the E2C reaction).
2. *Effect of Solvent on Elimination versus Substitution.* Increasing polarity of solvent favors S_N2 reactions at the expense of E2. In the classical example, alcoholic KOH is used to effect elimination, while the more polar aq KOH is used for substitution. Charge-dispersal discussions, similar to those in Section 10.G.iv,[124] only partially explain this. In most solvents, S_N1 reactions are favored over E1. The E1 reactions compete best in polar solvents that are poor nucleophiles, especially dipolar aprotic solvents[125] A study made in the gas phase, where there is no solvent, has shown that

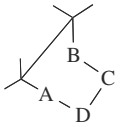
when 1-bromopropane reacts with MeO^- only elimination takes place (no substitution) even with this primary substrate.[126]

3. *Effect of Temperature.* Elimination is favored over substitution by increasing temperature, whether the mechanism is first or second order.[127] The reason is that the activation energies of eliminations are higher than those of substitutions (because eliminations have greater changes in bonding).

17.E. MECHANISMS AND ORIENTATION IN PYROLYTIC ELIMINATIONS



17.E.i. Mechanisms[128]

Several types of compound undergo elimination on heating, with no other reagent present. Reactions of this type are often run in the gas phase. The mechanisms are obviously different from those already discussed, since all those require an external base, which may be the solvent, in one of the steps, and there is no external base or solvent present in pyrolytic elimination. Two mechanisms have been found to operate. One involves a cyclic transition state, which may be four, five, or six membered. Examples of each size are

(**17-4**) (**17-8**) (**17-13**)

In this mechanism, the two groups leave at about the same time and bond to each other as they are doing so. The designation is E^i in the Ingold terminology and *cyclo*-$D_ED_NA_n$ in the IUPAC system. The elimination must be syn and, for the four- and five-membered transition states, the four or five atoms making up the ring must be coplanar. Coplanarity is not required for the six-membered transition state, since there is room for the outside atoms when the leaving atoms are staggered.

As in the E2 mechanism, it is not necessary that the C—H and C—X bond be broken simultaneously in the transition state. In fact, there is also a spectrum of mechanisms here, ranging from a mechanism in which C—X bond breaking is a good deal more advanced

Rev.* ***1969****, 69*, 33.

than C—H bond breaking to one in which the extent of bond breaking is virtually identical for the two bonds. Evidence for the existence of the E^i mechanism includes:

1. The kinetics are first order, so only one molecule of the substrate is involved in the reaction (i.e., if one molecule attacked another, the kinetics would be second order in substrate).[129]
2. Free radical inhibitors do not slow the reactions, so no free radical mechanism is involved.[130]
3. The mechanism predicts exclusive syn elimination, and this behavior has been found in many cases.[131] The evidence is inverse to that for the anti E2 mechanism and generally involves the following facts: (1) an erythro isomer gives a *trans*-alkene and a threo isomer gives a *cis*-alkene; (2) the reaction takes place only when a cis β hydrogen is available; (3) if, in a cyclic compound, a cis hydrogen is available on only one side, the elimination goes in that direction. Another piece of evidence involves a pair of steroid molecules. In 3β-acetoxy-(*R*)-5α-methylsulfinylcholestane (**27** shows rings A and B of this compound) and in 3β-acetoxy-(*S*)-5α-methylsulfinylcholestane (**28**: rings A and B), the *only* difference is the configuration of oxygen and methyl about the sulfur. Yet pyrolysis of **27** gave only elimination to the 4-side (86% 4-ene), while **28** gave predominant elimination to the 6-side (65% 5-ene and 20% 4-ene).[132] Models show that interference from the 1- and 9-hydrogen atoms causes the two groups on the sulfur to lie *in front of it* with respect to the rings, rather than behind it. Since the sulfur is a stereogenic center, this means that in **27** the oxygen is near the 4-hydrogen, while in **28** it is near the 6-hydrogen. This experiment is compatible only with syn elimination.[133]

(**17-12**)

4. The ^{14}C isotope effects for the *Cope elimination* (**17-9**) show that both the C—H and C—N bonds have been extensively broken in the transition state.[134]
5. Some of these reactions have been shown to exhibit negative entropies of activation, indicating that the molecules are more restricted in geometry in the transition state than they are in the starting compound.

Where a pyrolytic elimination lies on the mechanistic spectrum seems to depend mostly on the leaving group. When this is halogen, all available evidence suggests that in the transition state the C—X bond is cleaved to a much greater extent than the C—H bond; that is, there is a considerable amount of carbocation character in the transition state. This

observation is in accord with the fact that a completely nonpolar four-membered cyclic transition state violates the *Woodward–Hoffmann rules* (see the similar case of Reaction **15-63**). Evidence for the carbocation-like character of the transition state when halide is the leaving group is that relative rates are in the order I > Br > Cl[135] (see Sec. 10.G.iii), and that the effects of substituents on reaction rates are in accord with such a transition state.[136] Rate ratios for pyrolysis of some alkyl bromides at 320 °C were ethyl bromide, 1; isopropyl bromide, 280; *tert*-butyl bromide, 78,000. Also, α-phenylethyl bromide had about the same rate as *tert*-butyl bromide. On the other hand, β-phenylethyl bromide was only slightly faster than ethyl bromide.[137] This result indicates that C—Br cleavage was much more important in the transition state than C—H cleavage, since the incipient carbocation was stabilized by a alkyl and α-aryl substitution, while there was no incipient carbanion to be stabilized by β aryl substitution. These substituent effects, as well as those for other groups, are very similar to the effects found for the S_N1 mechanism and thus in very good accord with a carbocation-like transition state.

For carboxylic esters, the rate ratios were much smaller,[138] although still in the same order, so that this reaction is closer to a pure E^i mechanism, although the transition state still has some carbocationic character. Other evidence for a greater initial C—O cleavage with carboxylic esters is that a series of 1-arylethyl acetates followed σ^+ rather than σ, showing carbocationic character at the 1 position.[139] The extent of E1 character in the transition state increases in the following order of ester types: acetate < phenylacetate < benzoate < carbamate < carbonate.[140] Cleavage of xanthates (Reaction **17-5**), cleavage of sulfoxides (Reaction **17-12**), the *Cope Reaction* (**17-9**), and Reaction **17-8** are probably very close to straight E^i mechanisms.[141]

The second type of pyrolysis mechanism is completely different and involves free radicals. Initiation occurs by pyrolytic homolytic cleavage. The remaining steps may vary, and a few are shown below. Free radical mechanisms are mostly found in pyrolyses of polyhalides and of primary monohalides,[142] although they also have been postulated in pyrolysis of certain carboxylic esters.[143] β-Elimination of tosyl radicals is known.[144] Much less is known about these mechanisms and we will not consider them further. Free radical eliminations in solution are also known, but are rare.[145]

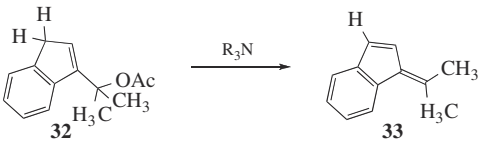
Termination (disproportionation)	$2\,R_2\dot{C}CH_2X$	$\longrightarrow R_2C{=}CH_2 + R_2CXCH_2X$

17.E.ii. Orientation in Pyrolytic Eliminations

As in the E1–E2–E1cB mechanistic spectrum, *Bredt's rule* applies; and if a double bond is present, a conjugated system will be preferred, if sterically possible. Apart from these considerations, the following statements can be made for E^i eliminations:

1. In the absence of considerations mentioned below, orientation is statistical and is determined by the number of β-hydrogen atoms available (therefore *Hofmann's rule* is followed). For example, *sec*-butyl acetate gives 55–62% 1-butene and 38–45% 2-butene,[146] which is close to the 3:2 distribution predicted by the number of hydrogen atoms available.[147]
2. A cis β hydrogen is required. Therefore in cyclic systems, if there is a cis hydrogen on only one side, the double bond will go that way. However, when there is a six-membered transition state, this does not necessarily mean that the leaving groups must be cis to each other, since such transition states need not be completely coplanar. If the leaving group is axial, then the hydrogen obviously must be equatorial (and consequently cis to the leaving group), since the transition state cannot be realized when the groups are both axial. But if the leaving group is equatorial, it can form a transition state with a β hydrogen that is either axial (hence, cis) or equatorial (hence, trans). Thus **29**, in which the leaving group is most likely axial, does not form a double bond in the direction of the carbethoxyl group, even though that would be conjugated, because there is no equatorial hydrogen on that side. Instead, it gives 100% **30**.[148] On the other hand, **31**, with an equatorial leaving group, gives ∼ 50% of each alkene, even though, for elimination to the 1-ene, the leaving group must depart with a trans hydrogen.[149]

29 **30** **31**



3. In some cases, especially with cyclic compounds, the more stable alkene forms and *Zaitsev's rule* applies. For example, menthyl acetate gives 35% of the *Hofmann product* and 65% of the *Zaitsev*, even though a cis β hydrogen is present on both sides and the statistical distribution is the other way. A similar result was found for the pyrolysis of menthyl chloride.[150]

[150] See Bamkole, T.; Maccoll, A. *J. Chem. Soc. B* ***1970***, 1159.

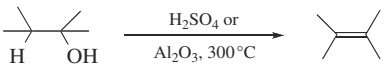
4. There are also steric effects. In some cases the direction of elimination is determined by the need to minimize steric interactions in the transition state or to relieve steric interactions in the ground state.

17.E.iii. 1,4-Conjugate Eliminations[151]

1,4-eliminations of the type H-C-C=CC-X → C=C-C=C are much rarer than conjugate additions (Chapter 15), but some examples are known.[152] One such is the conversion of **32** to **33**.[153]

17.F. REACTIONS

Reactions in which a C=C or a C≡C bond is formed will be considered first. From a synthetic point of view, the most important reactions for the formation of double bonds are **17-1** (usually by an E1 mechanism), **17-7**, **17-13**, and **17-22** (usually by an E2 mechanism), and **17-4**, **17-5**, and **17-9** (usually by an E^i mechanism). The only synthetically important method for the formation of triple bonds is **17-13**.[154] In the second section, reactions in which C≡N bonds and C=N bonds are formed will be considered, and then eliminations that give C=O bonds and diazoalkanes. Finally, extrusion reactions will be discussed.



17.F.i. Reactions in which C=C and C≡C Bonds Are Formed

A. Reactions in which Hydrogen Is Removed from One Side

In Reactions **17-1**–**17-6**, the other leaving atom is oxygen. In Reactions **17-7**–**17-11**, it is nitrogen. For reactions in which hydrogen is removed from both sides, see **19-1**–**19-6**.

17-1 Dehydration of Alcohols

Hydro-hydroxy-elimination

For a comparative study of various methods, see Mesnard, D.; Bernadou, F.; Miginiac, L. *J. Chem. Res. (S)* ***1981***, 270, and referrences cited therein.

Dehydration of alcohols can be accomplished in several ways. Both H_2SO_4 and H_3PO_4 are common reagents, but formation of an intermediate carbocation can lead to rearrangement products and to ether formation (Reaction **10-12**). If the alcohol is volatile, vapor-phase elimination over Al_2O_3 is an excellent method since side reactions are greatly reduced. This method has even been applied to such high-molecular-weight alcohols as 1-dodecanol.[155] Other metallic oxides (e.g., Cr_2O_3, TiO_2, WO_3) have been used, as have been sulfides, other metallic salts, and zeolites. The presence of an electron-withdrawing group usually facilitates elimination of water, as in the *aldol condensation* (Reaction **16-34**). Similarly, 2-nitroalcohols (products of the *Henry reaction*, **16-37**) give conjugated nitro compounds when heated with zeolite Y—Y.[156] Treating a 4-hydroxy lactam with DMAP and Boc anhydride leads to the conjugated lactam.[157] Elimination of serine derivatives to α-alkylidene amino acid derivatives was accomplished with $(EtO)_2POCl$.[158] Another method of avoiding side reactions is the conversion of alcohols to esters, followed by pyrolysis (**17-4**–**17-6**). The ease of dehydration increases with α branching, and tertiary alcohols are dehydrated so easily with only a trace of acid that it sometimes happens even when the investigator desires otherwise. Indeed, the initial alcohol products of many base-catalyzed condensations dehydrate spontaneously after an acid workup (Chapter 16) because the new double bond can be in conjugation with one already there.

Many other dehydrating agents[159] have been used on occasion: P_2O_5, I_2, and PPh_3—I_2,[160] BF_3–etherate, DMSO, SiO_2—Cl/Me_3SiCl,[161] $KHSO_4$ anhydrous $CuSO_4$, and phthalic anhydride, among others. Secondary and tertiary alcohols can also be dehydrated, without rearrangements, simply on refluxing in HMPA.[162] With nearly all reagents, dehydration follows *Zaitsev's rule.* An exception involves the passage of hot alcohol vapors over thorium oxide at 350–450 °C, under which conditions *Hofmann's rule* is followed.[163]

Transition metals can induce the dehydration of certain alcohols. β-Hydroxy ketones are converted to conjugated ketones by treatment with $CeCl_3$ and NaI.[164] In the presence of a Pd complex, alkyl cyclopropanols undergo a dehydration reaction to give a conjugated ketone.[165] A δ-hydroxy-α,β-unsaturated aldehyde was converted to a dienyl aldehyde with a Hf catalyst.[166] β-Hydroxy esters are converted to conjugated esters when treated with 2 molar equivalents of SmI_2.[167] The reaction of a β-hydroxy nitrile

with MeMgCl[168] or with MgO[169] leads to a conjugated nitrile. In another variation of the dehydration reaction, vicinal bromohydrins are converted to alkenes upon treatment with In, $InCl_3$, and a Pd catalyst.[170] Chlorohydrins react similarly when treated with Sm, and then diiodomethane.[171]

Carboxylic acids can be dehydrated by pyrolysis to give a ketene: $RCH_2CO_2H \rightarrow RCH{=}C{=}O$. Ketene itself is commercially prepared in this manner. Carboxylic acids have been converted to ketenes by treatment with certain reagents, including TsCl,[172] dicyclohexylcarbodiimide,[173] and 1-methyl-2-chloropyridinium iodide (*Mukaiyama's reagent*).[174] Analogously, amides can be dehydrated with P_2O_5, pyridine, and Al_2O_3 to give ketenimines:[175]

There is no way in which dehydration of alcohols can be used to prepare triple bonds: *gem*-diols and vinylic alcohols are not normally stable compounds and *vic*-diols[176] give either conjugated dienes or lose only 1 equiv of water to give an aldehyde or ketone. Dienes can be prepared, however, by heating alkynyl alcohols with triphenylphosphine.[177]

When proton acids catalyze alcohol dehydration, the mechanism is E1.[178] The principal process involves conversion of ROH to ROH_2^+ and cleavage of the latter to R^+ and H_2O, although with some acids a secondary process probably involves conversion of the alcohol to an inorganic ester and ionization of that ester (illustrated for H_2SO_4):

$$ROH \xrightarrow{H_2SO_4} ROSO_2OH \longrightarrow R^+ + HSO_4^-$$

Note that these mechanisms are the reverse of those involved in the acid-catalyzed hydration of double bonds (Reaction **15-3**), in accord with the principle of microscopic reversibility. With anhydrides (e.g., P_2O_5, phthalic anhydride), as well as with some other reagents (e.g., HMPA),[179] it is likely that an ester is formed, and the leaving group is the conjugate base of the corresponding acid. In these cases, the mechanism can be E1 or E2. The mechanism with Al_2O_3 and other solid catalysts has been studied extensively, but is poorly understood.[180]

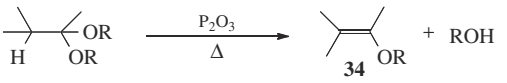
Magnesium alkoxides (formed by $ROH + Me_2Mg \rightarrow ROMgMe$) have been decomposed thermally, by heating at 195–340 °C to give the alkene, CH_4, and MgO.[181] Syn elimination is found and an E^i mechanism is likely. Similar decomposition of aluminum and zinc alkoxides has also been accomplished.[182]

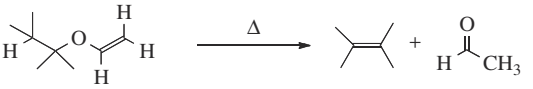
See also, OS **VII**, 63; **VIII**, 306, 474. No attempt has been made to list alkene-forming dehydration reactions accompanying condensations or rearrangements.

17-2 Cleavage of Ethers to Alkenes



Hydro-alkoxy-elimination

Alkenes can be formed by the treatment of ethers with very strong bases (e.g., alkylsodium or alkyllithium[183] compounds, sodium amide,[184] or LDA),[185] although there are side reactions with many of these reagents. The reaction is aided by electron-withdrawing groups in the β position, and, for example, $EtOCH_2CH(COOEt)_2$ can be converted to $CH_2{=}C(COOEt)_2$ without any base at all, but simply by heating.[186] *tert*-Butyl ethers are cleaved more easily than others. Several mechanisms are possible. In many cases, the mechanism is probably E1cB or on the E1cB side of the mechanistic spectrum,[187] since the base required is so strong, but it has been shown (by the use of $PhCD_2OEt$) that $PhCH_2OEt$ reacts by the five-membered E^i mechanism:[188] Propargylic benzyl ethers are converted to conjugated dienes by heating with a Ru catalyst.[189] Ethers also have been converted to alkenes and alcohols by passing vapors over hot P_2O_5 or Al_2O_3 (this method is similar to Reaction **17-1**), but this is not a general reaction.



Cyclic ethers (e.g., THF) react slowly with organolithium reagents with cleavage that produces a C=C unit.[190] Fragmentation of 2,5-dihydrofuran with ethylmagnesium chloride and a chiral Zr catalyst leads to a chiral, homoallylic alcohol.[191] Acetals can be converted to enol ethers (**34**) in this manner. When ketals react with 2 molar equivalents of tri-isobutylaluminum, the product is a vinyl ether.[192] This can also be done at room temperature by treatment with trimethylsilyl triflate and a tertiary amine[193] or with Me_3SiI in the presence of hexamethyldisilazane.[194]

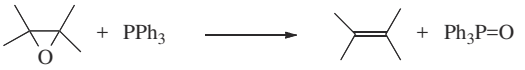
Conversion of a carbonyl compound to an enol phosphate[195] or triflate[196] allows a subsequent elimination reaction to give an alkyne. Conversion of an aldehyde to the vinyl nonaflate (nonafluorobutane-1-sulfonyl) was followed by reaction with a phosphazene base to give the alkyne.[197]

Enol ethers can be pyrolyzed to alkenes and aldehydes in a manner similar to that of Reaction **17-4**



The rate of this reaction for R–O–CH=CH_2 increased in the order Et < *i*Pr < *t*-Bu.[198] The mechanism is similar to that of Reaction **17-4**.

17-3 The Conversion of Epoxides and Episulfides to Alkenes

epi-Oxy-elimination

Epoxides can be converted to alkenes[199] by treatment with triphenylphosphine[200] or triethylphosphite $P(OEt)_3$.[201] The first step of the mechanism is nucleophilic substitution (Reaction **10-35**), followed by a four-center elimination. Since inversion accompanies the substitution, the overall elimination is anti; that is, if two groups A and C are cis in the epoxide, they will be trans in the alkene:

Alternatively, the epoxide can be treated with lithium diphenylphosphide (Ph_2PLi), and the product quaternized with methyl iodide.[202] Alkenes have also been obtained from epoxides

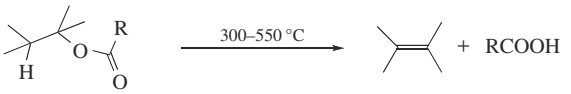
by reaction with a large number of reagents,[203] among them Li in THF,[204] trimethylsilyl iodide,[205] $F_3COOH—NaI$,[206] and compounds of Sm,[207] Mo, In,[208] and the W reagents mentioned in Reaction **17-18**. Some of these methods give syn elimination. Treatment of cyclooctane oxide with $Ph_3P—OPPh_3$ and NEt_3 gave cyclooctadiene.[209] Sodium amalgam with a Co–salen complex converted epoxides to alkenes.[210]

Epoxides can be converted to allylic alcohols[211] by treatment with several reagents, including *sec*-butyllithium,[212] and $i Pr_2NLi—t$-BuOK (the *LIDAKOR reagent*).[213] These bases remove the proton from the adjacent carbon, leading to formation of a C=C unit and opening of the epoxide to give an alkoxide. Phenyllithium reacts with epoxides in the presence of LTMP to give a *trans*-alkene.[214] Sulfur ylids (e.g., $Me_2S{=}CH_2$) also convert epoxides to allylic alcohols.[215] Bromomethyl epoxides react with $InCl_3/NaBH_4$ to give an allylic alcohol[216] or with $Me_3S^+Br^-$ and butyllithium to give a dienyl alcohol.[217] α,β-Epoxy ketones are converted to conjugated ketones by treatment with NaI in acetone in the presence of Amberlyst 15,[218] or with 2.5 molar equivalents of SmI_2.[219]



When an optically active reagent is used, optically active allylic alcohols can be produced from achiral epoxides.[220] Sparteine and *sec*-butyllithium generate a chiral base that leads to formation of chiral allylic alcohols.[221] Chiral diamines react with organolithium reagents to produce chiral bases that convert epoxides to allylic alcohols with good enantioselectivity.[222] Chiral diamines with a mixture of LDA and DBU (Reactions **15-32** and **17-13**) give similar results.[223]

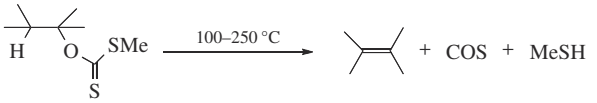
Episulfides[224] can be converted to alkenes.[225] However, in this case the elimination is syn, so the mechanism cannot be the same as that for conversion of epoxides. The phosphite attacks sulfur rather than carbon. Among other reagents that convert episulfides to alkenes are certain Rh complexes,[226] $LiAlH_4$[227] (this compound behaves quite differently with epoxides, see Reaction **19-35**), and MeI.[228] Episulfoxides can be converted to alkenes and sulfur monoxide simply by heating.[229]

17-4 Pyrolysis of Carboxylic Acids and Esters of Carboxylic Acids

Hydro-acyloxy-elimination



Direct elimination of a carboxylic acid (decarboxylation) to an alkene has been accomplished by heating in the presence of Pd catalysts.[230] Carboxylic esters that bear an alkyl group with a β hydrogen can be pyrolyzed, most often in the gas phase, to give the corresponding acid and an alkene.[231] No solvent is required. Since rearrangement and other side reactions are few, the reaction is synthetically very useful and is often carried out as an indirect method of accomplishing **17-1**. The yields are excellent and the workup is easy. Many alkenes have been prepared in this manner. For higher alkenes (above $\sim C_{10}$) a better method is to pyrolyze the alcohol in the presence of acetic anhydride.[232]

The mechanism is E^i (see Sec. 17.E.i). Lactones can be pyrolyzed to give unsaturated acids, provided that the six-membered transition state required for E^i reactions is available (it is not for five- and six-membered lactones, but it is for larger rings[233]). Amides give a similar reaction, but require higher temperatures.

Allylic acetates give dienes when heated with certain Pd[234] or Mo[235] compounds.

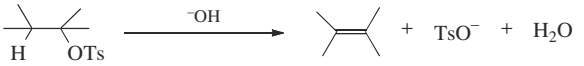
Methyl xanthates are prepared by treatment of alcohols with NaOH and CS_2 to give RO—C(=S)—SNa, followed by treatment of this with iodomethane.[236] Pyrolysis of the xanthate to give the alkene, COS, and the thiol is called the *Chugaev reaction*.[237] The reaction is like **17-4**; an indirect method of accomplishing **17-2**. The temperatures required with xanthates are lower than with ordinary esters, which is advantageous because possible isomerization of the resulting alkene is minimized. The mechanism is E^i, similar to that of Reaction **17-4**. For a time, there was doubt as to which sulfur atom closed the ring, but now there is much evidence, including the study of ^{34}S and ^{13}C isotope effects, to show that it is the C=S sulfur (see **35**).[238] In a structural variation of this reaction, heating a propargylic xanthate with 2,4,6-trimethylpyridinium trifluoromethyl sulfonate leads to formation of an alkene.[239]



The mechanism is thus exactly analogous to that of Reaction **17-5**.

OS **VII**, 139.

17-6 Decomposition of Other Esters

Hydro-tosyloxy-elimination

Several types of inorganic ester can be cleaved to alkenes by treatment with bases. Esters of sulfuric, sulfurous, and other acids undergo elimination in solution by E1 or E2 mechanisms, as do tosylates and other esters of sulfonic acids.[240] It has been shown that bis(tetra-*n*-butylammonium) oxalate, $(Bu_4N^+)_2\ (COO^-)_2$, is an excellent reagent for inducing tosylates to undergo elimination rather than substitution.[241] Aryl sulfonates have also been cleaved without a base. Esters of 2-pyridinesulfonic acid and 8-quinolinesulfonic acid gave alkenes in high yields simply on heating, without a solvent.[242] Phosphonate esters have been cleaved to alkenes by treatment with *Lawesson's reagent*[243] (see Reaction **16-11**).

17-7 Cleavage of Quaternary Ammonium Hydroxides

Hydro-trialkylammonio-elimination

Cleavage of quaternary ammonium hydroxides is the final step of the process known as *Hofmann exhaustive methylation* or *Hofmann degradation* or just *Hofmann elimination*.[244] In the first step, a primary, secondary, or tertiary amine is treated with enough iodomethane to convert it to the quaternary ammonium iodide (Reaction **10-31**). In the second step, the iodide counterion is converted to the hydroxide counterion by treatment with silver oxide. In the cleavage step, an aqueous or alcoholic solution of the ammonium hydroxide is distilled, often under reduced pressure. The decomposition generally takes place between 100 and 200 °C. Alternatively, the solution can be concentrated to a syrup by distillation or freeze-drying.[245] When the syrup is heated at low pressures, the cleavage reaction takes place at lower temperatures than are required for the reaction in the ordinary solution, probably because the base (HO^- or RO^-) is less solvated.[246] The reaction has never been an important synthetic tool, but has been used in the determination of the structure of unknown amines, especially alkaloids. In many of these compounds, the nitrogen is in a ring, or even at a ring junction, and in such cases formation of the alkene is incomplete. Repetitions of the process are required to remove the nitrogen completely, as in the conversion of 2-methylpiperidine to 1,5-hexadiene by two rounds of exhaustive methylation followed by pyrolysis.

A side reaction involving nucleophilic substitution to give an alcohol ($R_4N^+ \ ^-OH \rightarrow ROH + R_3N$) generally accompanies the normal elimination reaction,[247] but seldom causes trouble. However, when none of the four groups on the nitrogen has a β hydrogen, substitution is the only reaction possible. On heating $Me_4N^+ \ ^-OH$ in water, methanol is obtained, although without a solvent the product is not methanol, but dimethyl ether.[248]

The mechanism of elimination is usually E2 in protic solvents. *Hofmann's rule* is generally obeyed by acyclic and *Zaitsev's rule* by cyclohexyl substrates (Sec. 17.B, category 4). In certain cases, where the molecule is highly hindered or if the ammonium hydroxide is heated without solvent (neat), a five-membered E^i mechanism, similar to that in Reaction **17-8**, has been shown to operate. That is, the hydroxide in these cases does not attract the β hydrogen, but instead removes one of the methyl hydrogen atoms (see **36**), which removes a proton from the less substituted β-carbon atom to give the less substituted alkene with loss of the amine. It is also possible that the hydroxide (rather than the *N*-ylid) removes the β-hydrogen atom via an eclipsed rotamer in which the hydroxide is tethered to the ammonium unit and a syn-transition state is lower in energy.

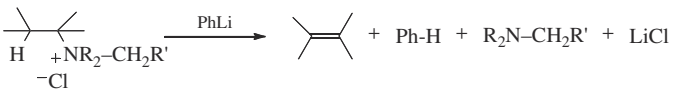
36

The obvious way to distinguish between this mechanism and the ordinary E2 mechanism is by the use of deuterium labeling. For example, if the reaction is carried out on a quaternary hydroxide deuterated on the β carbon ($R_2CDCH_2NMe_3^+ \ ^-OH$), the fate of the deuterium indicates the mechanism. If the E2 mechanism were in operation, the trimethylamine produced would contain no deuterium, which would be found only in the water. But if the mechanism is E^i, the amine would contain deuterium. In the case of the highly hindered compound $(Me_3C)_2CDCH_2NMe_3^+ \ ^-OH$, the deuterium did appear in the amine, demonstrating an E^i mechanism for this case.[249] With simpler compounds, the mechanism is E2, since here the amine was deuterium-free.[250]

When the nitrogen bears more than one group possessing a β hydrogen, which group cleaves? The *Hofmann rule* says that *within* a group the hydrogen on the least alkylated carbon cleaves. This tendency is also carried over to the choice of which group cleaves: thus ethyl with three β-hydrogen atoms cleaves more readily than any longer *n*-alkyl group, all of which have two β-hydrogen atoms. "The β hydrogen is removed most readily if it is located on a methyl group, next from RCH_2, and least readily from R_2CH."[251] In fact, the *Hofmann rule* as first stated[252] in 1851 applied only to which group cleaved, not to the orientation within a group. The latter could not have been specified in 1851, since the structural theory of organic compounds was not formulated until 1857–1860. Of course, the *Hofmann rule* (applied to which group cleaves *or* to orientation within a group) is superseded by conjugation possibilities. Thus $PhCH_2CH_2N^+Me_2Et \ ^-OH$ gives mostly styrene instead of ethylene.



Triple bonds have been prepared by pyrolysis of 1,2-bis(ammonium) salts.[253]

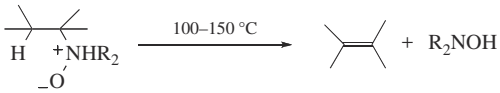
When quaternary ammonium halides are treated with strong bases (e.g., PhLi, KNH_2 in liquid NH_3[254]), an elimination can occur that is similar in products, although not in mechanism, to Reaction **17-7**. This is an alternative to Reaction **17-7** and is done on the quaternary ammonium halide, so that it is not necessary to convert this to the hydroxide. The mechanism is E^i:

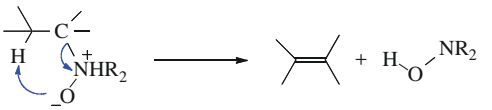


An α′ hydrogen is obviously necessary in order for the ylid to be formed. This type of mechanism is called α′,β elimination, since a β hydrogen is removed by the α′ carbon. The mechanism has been confirmed by labeling experiments similar to those described at Reaction **17-7**,[255] and by isolation of the intermediate ylids.[256] An important synthetic difference between this and most instances of Reaction **17-7** is that syn elimination is observed here and anti elimination in Reaction **17-7**, so products of opposite configuration are formed when the alkene exhibits cis–trans isomerism.

An alternative procedure that avoids the use of a very strong base is heating the salt with KOH in polyethylene glycol monomethyl ether.[257]

Benzotriazole has been shown to be a good leaving group for elimination reactions. The reaction of an allylic benzotriazole (3-benzotriazoyl-4-trimethylsilyl-1-butene) with *n*-butyllithium, and then an alkyl halide leads to an alkylated 1,3-diene upon heating.[258]

17-9 Cleavage of Amine Oxides



Hydro-(Dialkyloxidoammonio)-elimination

Cleavage of amine oxides to produce an alkene and a hydroxylamine is called the *Cope reaction* or *Cope elimination* (not to be confused with the Cope *rearrangement*, **18-32**). It is an alternative to Reactions **17-7** and **17-8**.[259] The reaction is usually performed with a mixture of amine and oxidizing agent (see **19-29**) without isolation of the amine oxide. Because of the mild conditions, side reactions are few, and the alkenes do not usually rearrange. The reaction is thus very useful for the preparation of many alkenes. A limitation is that it does not open six-membered rings containing nitrogen, although it does open rings of 5 and 7–10 members.[260] Rates of the reaction increase with increasing size of α- and

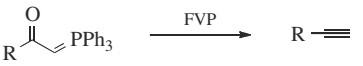
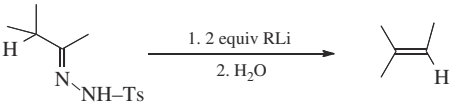
β-substituents.[261] The reaction can be carried out at room temperature in dry Me_2SO or THF.[262] The influence of solvent effects has been examined.[263] The elimination is a stereoselective syn process,[264] and the five-membered E^i mechanism operates:



Almost all evidence indicates that the transition state must be planar. Deviations from planarity as in Reaction **17-4** (see Sec. 17.E.i) are not found here, and indeed this is why six-membered heterocyclic nitrogen compounds do not react. Because of the stereoselectivity of this reaction and the lack of rearrangement of the products, it is useful for the formation of *trans*-cycloalkenes (eight-membered and higher). A polymer-bound *Cope elimination* reaction has been reported.[265]

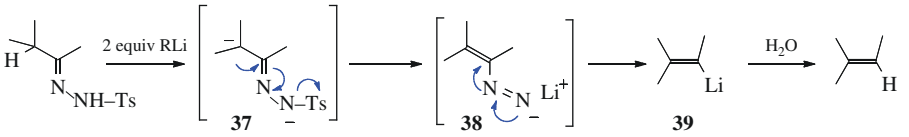
OS **IV**, 612.



17-10 Pyrolysis of Keto-ylids

Hydro-(oxophosphoryl)-elimination

Phosphorus ylids are quite common (see Reaction **16-44**) and keto-phosphorus ylids ($RCOCH{=}PPh_3$) are also known. When these compounds are heating (flash vacuum pyrolysis, FVP) to $> 500\ ^\circ C$, alkynes are formed. Simple alkynes[266] can be formed as well as keto-alkynes[267] and en-ynes.[268] Rearrangement from ylids derived from tertiary amines and α-diazo ketones is also known.[269]



17-11 Decomposition of Toluene-p-sulfonylhydrazones

Treatment of the tosylhydrazone of an aldehyde or a ketone with a strong base leads to the formation of an alkene, the reaction being formally an elimination accompanied by a hydrogen shift.[270] The reaction (called the *Shapiro reaction*) has been applied to

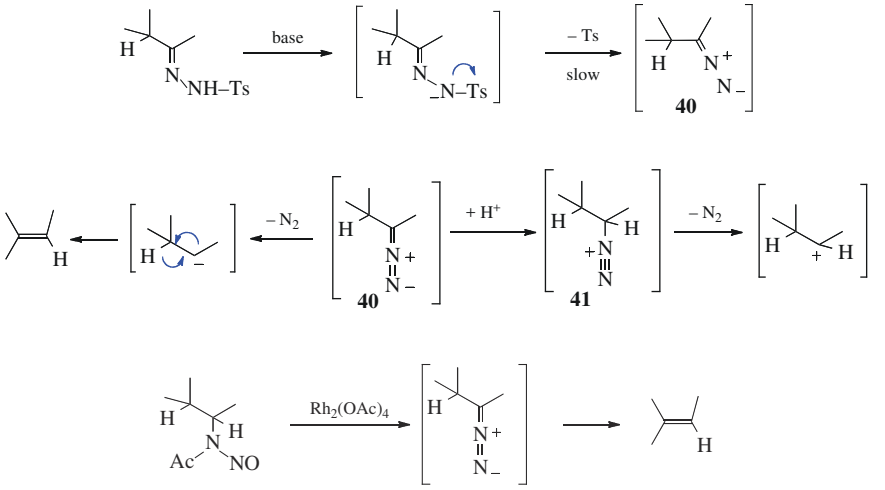
tosylhydrazones[271] of many aldehydes and ketones. The most useful synthetic method involves treatment of the substrate with at least 2 molar equivalents of an organolithium compound[272] (usually MeLi) in ether, hexane, or tetramethylenediamine.[273] This procedure gives good yields of alkenes without side reactions and, where a choice is possible, predominantly gives the less highly substituted alkene. Tosylhydrazones of α,β-unsaturated ketones give conjugated dienes.[274] The mechanism[275] has been formulated as that shown.



Evidence for this mechanism is (1) two molar equivalents of RLi are required; (2) the hydrogen in the product comes from the water and not from the adjacent carbon, as shown by deuterium labeling;[276] and (3) the intermediates **37–39** have been trapped.[277] This reaction, when performed in tetramethylenediamine, can be a synthetically useful method[278] of generating vinylic lithium compounds (**39**), which can be trapped by various electrophiles[279] (e.g., D_2O, to give deuterated alkenes), CO_2 (to give α,β-unsaturated carboxylic acids, Reaction **16-30**), or DMF (to give α,β-unsaturated aldehydes, Reaction **16-82**). Treatment of *N*-aziridino hydrazones with LDA leads to alkenes with high cis selectivity.[280]

The reaction also takes place with other bases (e.g., NaH, LiH,[281] Na in ethylene glycol, $NaNH_2$) or with smaller amounts of RLi, but in these cases side reactions are common and the orientation of the double bond is in the other direction (to give the more highly substituted alkene). The reaction with Na in ethylene glycol is called the *Bamford–Stevens reaction*.[282] For these reactions, two mechanisms are possible: a carbenoid and a carbocation mechanism.[283] The side reactions found are those expected of carbenes and carbocations. In general, the carbocation mechanism is chiefly found in protic solvents and the carbenoid mechanism in aprotic solvents. Both routes involve formation of a diazo compound (**40**), which in some cases can be isolated. In fact, this reaction has been used as a synthetic method for the preparation of diazo compounds.[284] In the absence of protic solvents, **36** loses N_2, and hydrogen migrates, to give the alkene product. The migration of hydrogen may immediately follow, or be simultaneous with, the loss of N_2. In a protic

solvent, **40** becomes protonated to give the diazonium ion **41**, which loses N_2 to give the corresponding carbocation, that may then undergo elimination or give other reactions characteristic of carbocations. A diazo compound is an intermediate in the formation of alkenes by treatment of *N*-nitrosoamides with a Rh(II) catalyst.[285]

17-12 Cleavage of Sulfoxides, Selenoxides, and Sulfones

Hydro-alkylsulfinyl-elimination

Hydro-alkylsulfinyl-elimination

Sulfonium compounds (—C—$^{+}SR_2$) undergo elimination similar to that of their ammonium counterparts (Reactions **17-7** and **17-8**) in scope and mechanism, but this reaction is not of great synthetic importance. These syn-elimination reactions are related to the *Cope eln* (Reaction **17-9**) and *Hofmann elimination* (Reaction **17-7**).[286]

[285] Godfrey, A.G.; Ganem, B. *J. Am. Chem. Soc.* ***1990****, 112,* 3717.
[286] See Smith, M.B. *Organic Synthesis*, 3rd ed., Wavefunction Inc./Elsevier, Irvine, CA/London, England, ***2010***, pp. 161–171.

Sulfones and sulfoxides[287] with a β hydrogen, on the other hand, undergo elimination on treatment with an alkoxide or, for sulfones,[288] even with hydroxide.[289] Sulfones also eliminate in the presence of an organolithium reagent and a Pd catalyst.[290] Mechanistically, these reactions belong on the E1–E2–E1cB spectrum.[291] Although the leaving groups are uncharged, the orientation follows *Hofmann's rule*, not *Zaitsev's*. Sulfoxides (but not sulfones) also undergo elimination upon pyrolysis at ∼ 80 °C in a manner analogous to Reaction **17-9**. The mechanism is also analogous, being the five-membered E^i mechanism with syn elimination.[292]

Selenoxides[293] and sulfinate esters ($R_2CH—CHR—SO—OMe$)[294] also undergo elimination by the E^i mechanism, and the selenoxide reaction takes place at room temperature. The reaction with selenoxides has been extended to the formation of triple bonds.[295]

Both α-keto selenoxides[296] and sulfoxides[297] have been used in a method for the conversion of ketones, aldehydes, and carboxylic esters to their α,β-unsaturated derivatives. Allylic sulfoxides undergo 1,4-elimination to give dienes.[298]

A radical elimination reaction generates alkenes from sulfoxides. The reaction of a 2-bromophenyl alkylsulfoxide with Bu_3SnH and AIBN (see Sec. 14.A.i for a discussion of these standard radical conditions) leads to an alkene.[299]

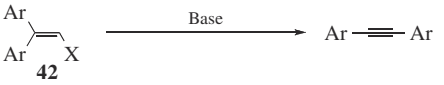
most frequently used base, although stronger bases[301] (^-OR, $^-NH_2$, etc.) or weaker ones (e.g., amines) are used where warranted.[302] The bicyclic amidines 1,5-diazabicyclo[3.4.0] non-5-ene (DBN)[303] and DBU[304] are good reagents for difficult cases.[305] Solvation by HMPA promotes LDA mediated dehydrobromination.[306]

DBN DBU

Dehydrohalogenation with the non-ionic base $(Me_2N)_3P{=}N\text{-}P(NMe_3)_2{=}NMe$ is even faster.[307] A Co catalyst with dimethylphenylsilylmethylmagnesium chloride leads to formation of terminal alkenes from 2° alkyl bromides.[308] Phase-transfer catalysis has been used with hydroxide as base.[309] As previously mentioned (Sec. 17.A.v), certain weak bases in dipolar aprotic solvents are effective reagents for dehydrohalogenation. Among those most often used for synthetic purposes are LiCl or LiBr-$LiCO_3$ in DMF.[310] Dehydrohalogenation occurs by simply heating the alkyl halide in HMPA with no other reagent present.[311] As in nucleophilic substitution (Sec. 10.G.iii), the order of leaving group reactivity is $I > Br > Cl > F$.[312] Tertiary halides undergo elimination most easily. Eliminations of chlorides, bromides, and iodides follow *Zaitsev's rule,* except for a few cases where steric effects are important (e.g., see Sec. 17.B, category 4). Eliminations of fluorides follow *Hofmann's rule* (Sec. 17.B, category 4).



This reaction is by far the most important way of introducing a triple bond into a molecule.[313] Alkyne formation can be accomplished with substrates of the types:[314]

When the base is $NaNH_2$, 1-alkynes predominate (where possible), because this base is strong enough to form the salt of the alkyne, shifting any equilibrium between 1- and

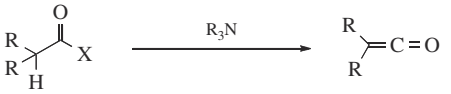
2-alkynes. When the base is $^-$OH or $^-$OR, the equilibrium tends to be shifted to the internal alkyne, which is thermodynamically more stable. If another hydrogen is suitably located (e.g., —CRH—CX_2—CH_2—), allene formation can compete, although alkynes are usually more stable. Tetrabutylammonium fluoride mediates the dehydrobromination of vinyl bromide to terminal alkynes.[315] Treatment of 1,1-dibromo-1-alkenes with a Pd-catalyst, followed by reaction with tetrabutylammonium hydroxide gives an internal alkyne.[316]

42

1,1-Dibromoalkenes are converted to alkynes when treated with *n*-butyllithium.[317] This transformation is a modification of the *Fritsch–Buttenberg–Wiechell rearrangement* in which a 1,1-diaryl vinyl bromide (**42**) gives a diaryl alkyne upon treatment with base.[318] Vinyl sulfoxides that contain a leaving group (e.g., chloride) on the double bond react with *tert*-butyllithium to give a lithio alkyne, and hydrolysis leads to the final product, an alkyne.

Dehydrohalogenation is generally carried out in solution, with a base, and the mechanism is usually E2, although the E1 mechanism has been demonstrated in some cases. However, elimination of HX can be accomplished by pyrolysis of the halide, in which case the mechanism is E^i (Sec. 17.E.i) or, in some instances, the free radical mechanism (Sec. 17.E.i). Pyrolysis is normally performed without a catalyst at $\sim$ 400 °C. The pyrolysis reaction is not generally useful synthetically, because of its reversibility. Less work has been done on pyrolysis with a catalyst[319] (usually a metallic oxide or salt), but the mechanisms here are probably E1 or E2.

43



In the special case of the prochiral carboxylic acids (**43**), dehydrohalogenation with an optically active lithium amide gave an optically active product with %ee as high as 82%.[320]

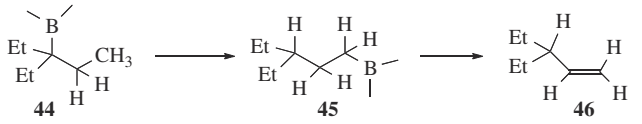
17-14 Dehydrohalogenation of Acyl Halides and Sulfonyl Halides

Hydro-halo-elimination

Ketenes can be prepared by treatment of acyl halides with tertiary amines[321] or with NaH and a crown ether.[322] The scope is broad, and most acyl halides possessing an α hydrogen give the reaction, but if at least one R is hydrogen, only the ketene dimer, not the ketene, is isolated. However, if a reactive ketene must be used in a reaction with a given compound, the ketene can be generated *in situ* in the presence of the given compound.[323]

Closely related is the reaction of tertiary amines with sulfonyl halides that contain an α hydrogen. In this case, the initial product is the highly reactive sulfene, which cannot be isolated but reacts further to give products, one of which may be the alkene that is the dimer of RCH.[324] Reactions of sulfenes *in situ* are also common (e.g., see **16-48**).

OS **IV**, 560; **V**, 294, 877; **VI**, 549, 1037; **VII**, 232; **VIII**, 82.



17-15 Elimination of Boranes

Hydro-boranetriyl-elimination

Trialkylboranes are formed from an alkene and BH_3 (Reaction **15-16**). When the resulting borane is treated with another alkene, an exchange reaction occurs.[325] This is an equilibrium process that can be shifted by using a large excess of alkene, by using an unusually reactive alkene, or by using an alkene with a higher boiling point than the displaced alkene and removing the latter by distillation. The reaction is useful for shifting a double bond in the direction opposite to that resulting from normal isomerization methods (**12-2**). This cannot be accomplished simply by treatment of a borane with an alkene, because elimination in this reaction follows *Zaitsev's rule*: It is in the direction of the most stable alkene. However, heating borane (**44**) leads to **45** (Reaction **18-11**) and when **45** is heated with a higher-boiling alkene (e.g., 1-decene), the exchange reaction gives **46**. These isomerizations proceed essentially without rearrangement. The mechanism is probably the reverse of borane addition (Reaction **15-16**).

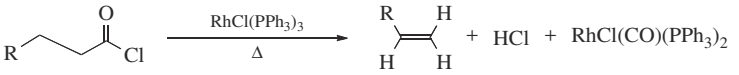
A similar reaction, but irreversible, has been demonstrated for alkynes.[326]

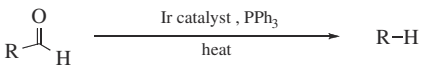
$$(R_2CH{-}CH_2)_3B + R'C{\equiv}CR' \longrightarrow 3\,R_2C{=}CH_2 + (R'CH{=}CR')_3B$$

17-16 Conversion of Alkenes to Alkynes



Hydro-methyl-elimination

Alkenes of the form shown lose the elements of methane when treated with sodium nitrite in acetic acid and water, to form alkynes in moderate-to-high yields.[327] The R may contain additional unsaturation, as well as OH, OR, OAc, C=O, and other groups, but the $Me_2C{=}CHCH_2{-}$ portion of the substrate is necessary for the reaction to take place. The mechanism is complex, beginning with a nitration that takes place with allylic rearrangement [$Me_2C{=}CHCH_2R \rightarrow H_2C{=}CMeCH(NO_2)CH_2R$], and involving several additional intermediates.[328] The CH_3 lost from the substrate appears as CO_2, as demonstrated by the trapping of this gas.[328]



17-17 Decarbonylation of Acyl Halides or Aldehydes

Hydro-chloroformyl-elimination

Acyl chlorides containing an α hydrogen are smoothly converted to alkenes, with loss of HCl and CO, upon heating with chlorotris(triphenylphosphine)rhodium, with metallic Pt, or with certain other catalysts.[329] The mechanism probably involves conversion of RCH_2CH_2COCl to $RCH_2CH_2{-}RhCO(Ph_3P)_2Cl_2$ followed by a concerted syn elimination of Rh and H[330] (see also, Reactions **14-32** and **19-12**).

Aldehydes are decarbonylated to give the corresponding hydrocarbon in the presence of an Ir catalyst and triphenylphosphine.

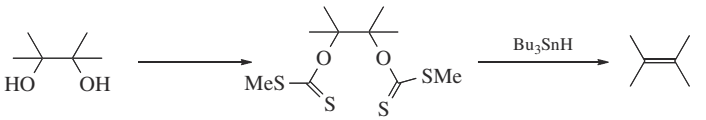
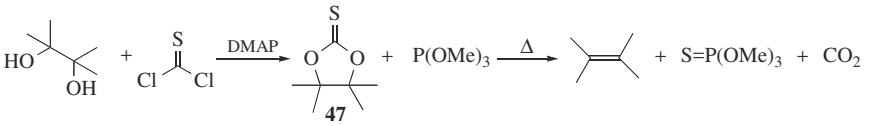
B. Reactions in which Neither Leaving Atom Is Hydrogen



17-18 Deoxygenation of Vicinal Diols

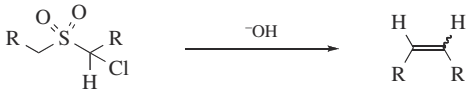
Dihydroxy-elimination



vic-Diols can be deoxygenated by treatment of the dilithium dialkoxide with the tungsten halide (K_2WCl_6), or with certain other tungsten reagents, in refluxing THF.[331] Tetrasubstituted diols react most rapidly. The elimination is largely, but not entirely, syn. Several other methods have been reported,[332] in which the diol is deoxygenated directly, without conversion to the dialkoxide. These include treatment with Ti metal,[333] with TsOH—NaI,[334] and by heating with $CpReO_3$,[335] where Cp is cyclopentadienyl.

vic-Diols can also be deoxygenated indirectly, through sulfonate ester derivatives. For example, *vic*-dimesylates and *vic*-ditosylates have been converted to alkenes by treatment, respectively, with naphthalene–sodium[336] and with NaI in DMF.[337] In another procedure, the diols are converted to bis(dithiocarbonates) [bis(xanthates)], which undergo elimination (probably by a free radical mechanism) when treated with tri-*n*-butylstannane in toluene or benzene.[338] *vic*-Diols can also be deoxygenated through cyclic derivatives (Reaction **17-19**).

17-19 Cleavage of Cyclic Thionocarbonates



Cyclic thionocarbonates (**47**) can be cleaved to alkenes (the *Corey–Winter reaction*)[339] by heating with trimethyl phosphite[340] or other trivalent phosphorus compounds[341] or by treatment with bis(1,5-cyclooctadiene)nickel.[342] The thionocarbonates (e.g., **47**) can be

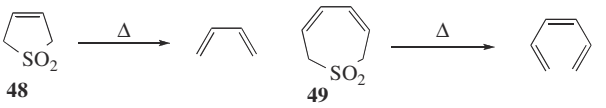
prepared by treatment of 1,2-diols with thiophosgene and DMAP.[343] The elimination is of course syn, so the product is sterically controlled. Alkenes that are not sterically favored can be made this way in high yield (e.g., *cis*-$PhCH_2CH{=}CHCH_2Ph$).[344] Certain other five-membered cyclic derivatives of 1,2-diols can also be converted to alkenes.[345]

17-20 The Ramberg–Bäcklund Reaction

Ramberg–Bäcklund halosulfone transformation

The reaction of an α-halo sulfone with a base to give an alkene is called the *Ramberg–Bäcklund reaction*.[346] The reaction is quite general for α-halo sulfones with an α′ hydrogen, despite the unreactive nature of α-halo sulfones in normal S_N2 reactions (Sec. 10.G.i, category 6). Halogen reactivity is in the order $I > Br \gg Cl$. Phase-transfer catalysis has been used.[347] In general, mixtures of cis and trans isomers are obtained, but usually the less stable cis isomer predominates. The mechanism involves formation of an episulfone, and then elimination of SO_2. There is much evidence for this mechanism,[348]



including the isolation of the episulfone intermediate,[349] and also the preparation of episulfones in other ways and the demonstration that they give alkenes under the reaction conditions faster than the corresponding α-halo sulfones.[350] Episulfones synthesized in other ways (e.g., Reaction **16-48**) are reasonably stable compounds, but eliminate SO_2 to give alkenes when heated or treated with base.

If the reaction is run on the unsaturated bromosulfones ($RCH_2CH{=}CHSO_2CH_2Br$, prepared by reaction of $BrCH_2SO_2Br$ with $RCH_2CH{=}CH_2$ followed by treatment with Et_3N), $RCH{=}CHCH{=}CH_2$ is produced in moderate-to-good yields.[351] The compound mesyltriflone ($CF_3SO_2CH_2SO_2CH_3$) can be used as a synthon for the tetraion $^{2-}C{=}C^{2-}$. Successive alkylation (Reaction **10-67**) converts it to $CF_3SO_2CR^1R^2SO_2CHR^3R^4$

(anywhere from one to four alkyl groups can be put in), which, when treated with base, gives $R^1R^2C{=}CR^3R^4$.[352] The nucleofuge here is the $CF_3SO_2^-$ ion. There is an example of a *Ramberg–Bäcklund reaction* that is induced by a *Michael addition*.[353]

48 **49**

2,5-Dihydrothiophene-1,1-dioxides (**48**) and 2,17-dihydrothiepin-1,1-dioxides (**49**) undergo analogous 1,4- and 1,6-eliminations, respectively (see also, Reaction **17-36**). These are concerted reactions and, as predicted by the orbital-symmetry rules (Reaction **15-50**. A, and immediately preceding pages), the former[354] is a suprafacial process and the latter[355] an antarafacial process. The rules also predict that elimination of SO_2 from episulfones cannot take place by a concerted mechanism (except antarafacially, which is unlikely for such a small ring), and evidence shows that this reaction occurs by a nonconcerted pathway.[356] The eliminations of SO_2 from **48** and **49** are examples of *cheletropic reactions*,[357] which are defined as reactions in which two σ bonds that terminate at a single atom (in this case the sulfur atom) are made or broken in concert.[358]

50 **51** **52**

α,α-Dichlorobenzyl sulfones (**50**) react with an excess of the base triethylenediamine (TED) in DMSO at room temperature to give 2,3-diarylthiiren-1,1-dioxides (**51**), which can be isolated.[359] Thermal decomposition of **51** gives the alkynes **52**.[360]

A *Ramberg–Bäcklund-type reaction* has been carried out on the α-halo *sulfides* ($ArCHClSCH_2Ar$), which react with *t*-BuOK and PPh_3 in refluxing THF to give the alkenes ($ArCH{=}CHAr$).[361] Cyclic sulfides lead to ring-contracted cyclic alkenes upon treatment with NCS in CCl_4 followed by oxidation with *m*-chloroperoxybenzoic acid.[362]

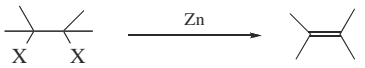
The *Ramberg–Bäcklund reaction* can be regarded as a type of extrusion reaction (see Sec. 17.F.vi).

OS **V**, 877; **VI**, 454, 555; **VIII**, 212.

17-21 The Conversion of Aziridines to Alkenes



epi-Imino-elimination

Aziridines not substituted on the nitrogen atom react with nitrous acid to produce alkenes.[363] An *N*-nitroso compound is an intermediate (Reaction **12-50**); other reagents that produce such intermediates also give alkenes. The reaction is stereospecific: *cis*-aziridines give *cis*-alkenes and *trans*-aziridines give *trans*-alkenes.[364] Aziridines carrying *N*-alkyl substituents can be converted to alkenes by treatment with ferrous iodide[365] or with *m*-chloroperoxybenzoic acid.[366] An *N*-oxide intermediate (Reaction **19-29**) is presumably involved in the latter case. *N*-Tosylaziridnes give allylic sulfonamides when treated with butyllithium.[367] *N*-Tosyl aziridines are converted to *N*-tosyl imines when treated with boron trifluoride.[368] 2-Tosylmethyl *N*-tosylaziridines react with Te^{2-} in the presence of Adogen 464 to give allylic *N*-tosyl amines.[369] 2-Halomethyl *N*-tosyl aziridines also react with In metal in methanol to give *N*-tosyl allylic amines.[370]

17-22 Elimination of Vicinal Dihalides

Dihalo-elimination

Dehalogenation has been accomplished with many reagents, the most common being Zn, Mg, and iodide ion.[371] Heating in HMPA is often enough to convert a *vic*-dibromide to an alkene.[372] Among reagents used less frequently have been phenyllithium, phenylhydrazine, $CrCl_2$, Na_2S in DMF,[373] and $LiAlH_4$.[374] Electrochemical reduction has also

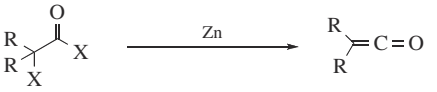
been used.[375] Treatment with In[376] or Sm[377] metal in methanol, $InCl_3/NaBH_4$,[378] heating with Zn in acetic acid,[379] or reaction of a *Grignard reagent* and $Ni(dppe)Cl_2$ (dppe = 1,2-diphenylphosphinoethane).[380] When the reagent is Zn, antistereospecificity has been observed in some cases,[381] but not in others.[382] Microwave irradiation of a *vic*-dibromide in an ionic liquid leads to the alkene.[383] The reaction of a vicinal dibromide with triethylamine and DMF with microwave irradiation leads to vinyl bromide.[384] α,β-Dibromo amides are converted to conjugated amides upon photolysis in methanol.[385]

One useful feature of this reaction is that there is no doubt about the *position* of the new double bond, so that it can be used to give double bonds exactly where they are wanted. For example, allenes, which are not easily prepared by other methods, can be prepared from X—C—CX_2—C—X or X—C—CX=C— systems.[386] Cumulenes have been obtained from 1,4-elimination:

$$BrCH_2—C{\equiv}C—CH_2Br + Zn \longrightarrow CH_2{=}C{=}C{=}CH_2$$

Cumulenes have also been prepared by treating alkynyl epoxides with boron trifluoride.[387] 1,4-Elimination of BrC—C=C—CBr has been used to prepare conjugated dienes C=C—C=C.[388] Allenes are formed by heating propargylic alcohols with arylboronic acids (Reaction **12-28**) and a Pd catalyst.[389] Allenes are also formed from propargylic amines using a CuI and a Pd catalyst.[390] In addition, allenes are formed from lithium bromocyclopropylidenoids.[391]



The reaction can be carried out for any combination of halogens, except where one is fluorine. Mechanisms are often complex and depend on the reagent and reaction conditions.[392] For different reagents, mechanisms involving carbocations, carbanions, and free radical intermediates, as well as concerted mechanisms, have been proposed.

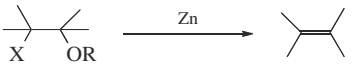
17-23 Dehalogenation of α-Halo Acyl Halides

Dihalo-elimination

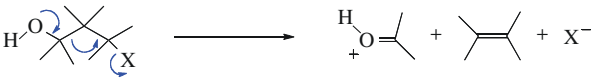


Ketenes can be prepared by dehalogenation of α-halo acyl halides with zinc or with triphenylphosphine.[393] The reaction generally gives good results when the two R groups are aryl or alkyl, but not when either one is hydrogen.[394]

OS **IV**, 348; **VIII**, 377.

17-24 Elimination of a Halogen and a Hetero Group

Alkoxy-halo-elimination



The elimination of OR and halogen from β-halo ethers is called the *Boord reaction*. It can be carried out with Zn, Mg, Na, or certain other reagents.[395] The yields are high and the reaction is of broad scope. β-Halo acetals readily yield vinylic ethers, X—C—C(OR)$_2$ → C=C—OR and 2 molar equivalents of SmI_2 in HMPA is effective.[396] Besides β-halo ethers, the reaction can also be carried out on compounds of the formula Z—C—C—Z where X is halogen and Z is OCOR, OTs,[397] NR_2,[398] or SR.[399] When X = Cl and Z = OAc, heating in THF with an excess of SmI_2 followed by treatment with dilute aq HCl gives an alkene.[400] When Z = I and the other Z is an oxygen of an oxazolone (a carbamate unit), heating with In metal in methanol leads to an allylic amine.[401] The Z group may also be OH, but then X is limited to Br and I.[402] Like Reaction **17-22**, this method ensures that the new double bond will be in a specific position. The fact that Mg causes elimination in these cases limits the preparation of *Grignard reagents* from these compounds. It has been shown that treatment of β-halo ethers and esters with Zn gives nonstereospecific elimination,[403] so the mechanism was not E2. An E1cB mechanism was postulated because of the poor leaving-group ability of OR and OCOR. Bromohydrins can be converted to alkenes (elimination of Br, OH) in high yields by treatment with $LiAlH_4$-$TiCl_3$.[404]

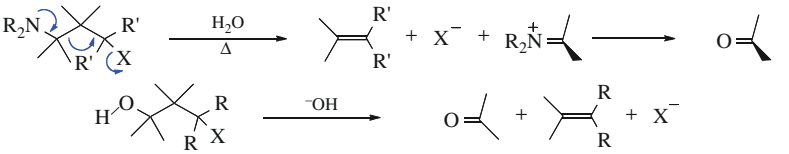
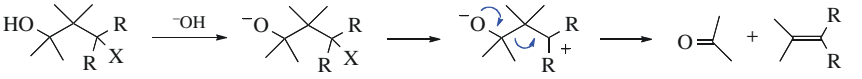
17.F.ii. Fragmentations

When carbon is the positive leaving group (the electrofuge) in an elimination, the reaction is called *fragmentation*.[405] These processes occur on substrates of the form W—C—C—X, where X is a normal nucleofuge (e.g., halogen, OH_2^+, OTs, NR_3^+) and W is a positive-carbon electrofuge. In most of the cases, W is HO—C— or R_2N—C—, so that the positive charge on the carbon atom is stabilized by the unshared pair of the oxygen or nitrogen, for example,



The mechanisms are mostly E1 or E2. We will discuss only a few fragmentations, since many are possible and not much work has been done on most of them. Reactions **17-25**–**17-28** and **17-30** may be considered fragmentations (see also, Reactions **19-12** and **19-13**).



17-25 1,3-Fragmentation of γ-Amino, γ-Hydroxy Halides and 1,3-Diols

Dialkylaminoalkyl-halo-elimination, and so on

Hydroxyalkyl-hydroxy-elimination

γ-Dialkylamino halides undergo fragmentation when heated with water to give an alkene and an iminium salt, which under the reaction conditions is hydrolyzed to an aldehyde or ketone (**16-2**).[406] γ-Hydroxy halides and tosylates are fragmented with base. In this instance, the base does not play its usual role in elimination reactions, but instead serves to remove a proton from the OH group, which enables the carbon leaving group to come off more easily:

Prelog and Zalán[407] first observed this type of fragmentation in work that solved the structure of quinine and other Cinchona alkaloids in a 1,3-elimination ring-opening reaction. Subsequent work by Grob[408] elucidated the mechanism of the reaction, and this 1,3-elimination is often referred to as *Grob fragmentation*.[409] The mechanism of these

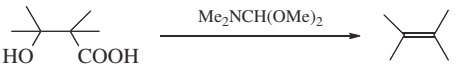
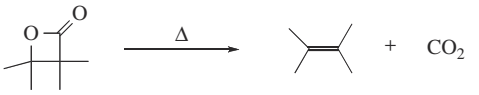
reactions is often E1, but an E2 mechanism also operates.[410] It has been shown that stereoisomers of cyclic γ-amino halides and tosylates in which the two leaving groups can assume an antiperiplanar conformation react by the E2 mechanism, while those isomers in which the groups cannot assume such a conformation either fragment by the E1 mechanism or do not undergo fragmentation at all, but in either case give rise to side products characteristic of carbocations.[411] An example of a *Grob fragmentation* is the conversion of **53** to **54**.[412]



γ-Dialkylamino alcohols do not give fragmentation, since for ionization the OH group must be converted to $^{+}OH_2$ and this would convert NR_2 to $^{+}NR_2H$, which does not have the unshared pair necessary to form the double bond with the carbon.[413]

1,3-Diols in which at least one OH group is tertiary or is located on a carbon with aryl substituents can be cleaved by acid treatment.[414] The reaction is most useful synthetically when at least one of the OH groups is on a ring.[415]

17-26 Decarboxylation of β-Hydroxy Carboxylic Acids and of β-Lactones



Carboxy-hydroxy-elimination

An OH and a CO_2H group can be eliminated from β-hydroxy carboxylic acids by refluxing with excess DMF dimethyl acetal.[416] Mono-, di-, tri-, and tetrasubstituted alkenes have been prepared by this method in good yields.[417] There is evidence that the mechanism involves E1 or E2 elimination from the zwitterionic intermediate $^{-}O_2C—C—C—O—C=N^{+}Me_2$.[418] The reaction has also been accomplished[419] under extremely mild conditions (a few seconds at 0 °C) with PPh_3 and $EtO_2C—N=N—CO_2Et$,

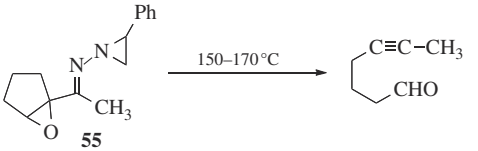
diethyl azodicarboxylate.[420] In a related procedure, β-lactones undergo thermal decarboxylation to give alkenes in high yields. The reaction has been shown to be stereospecific syn elimination.[421] There is evidence that this reaction also involves a zwitterionic intermediate.[422]



There are no OS references, but see OS **VII**, 172, for a related reaction.

17-27 Fragmentation of α,β-Epoxy Hydrazones

Eschenmoser–Tanabe ring cleavage

Cyclic α,β-unsaturated ketones[423] can be cleaved by treatment with base of their epoxy tosylhydrazone derivatives to give acetylenic ketones,[424] in what is known as the *Eschenmoser–Tanabe ring cleavage*. The reaction can be applied to the formation of acetylenic aldehydes (R = H) by using the corresponding, 2,4-dinitro-tosylhydrazone derivatives.[425] Hydrazones (e.g., **55**) prepared from epoxy ketones and ring-substituted *N*-aminoaziridines undergo similar fragmentation when heated.[426]

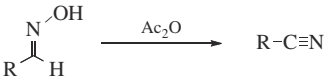
On heating, bicyclo[2.2.1]hept-2,3-en-17-ones (**56**) usually lose CO to give cyclohexadienes,[427] in a type of *reverse Diels–Alder reaction*. Bicyclo[2.2.1]heptadienones (**57**) undergo the reaction so readily (because of the stability of the benzene ring produced) that

57

58

they cannot generally be isolated. The parent (**57**) has been obtained at 10–15 K in an Ar matrix, where its spectrum could be studied.[428] Both **56** and **57** can be prepared by a *Diels-Alder reactions* between a cyclopentadienone and an alkyne or alkene, so that this reaction is a useful method for the preparation of specifically substituted benzene rings and cyclohexadienes.[429] Unsaturated bicyclic lactones of the type **58** can also undergo the reaction, losing CO_2 (see also, **17-35**).



OS **III**, 807; **V**, 604, 1037.

Reversal of the *Diels–Alder reaction* may be considered a fragmentation (see **15-50**).

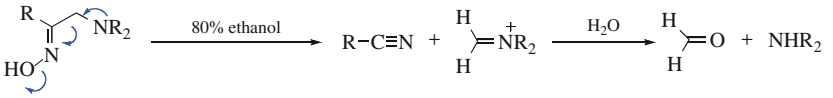
(room temperature) are $Ph_3P—CCl_4$,[432] $PPh_3—I_2$,[433] $Pd(OAc)_2/PPh_3$ in refluxing CH_3CN,[434] ferric sulfate,[435] Cu(II) with ultrasound,[436] and ZnO/CH_3COCl under solvent-free conditions.[437] *N,N*-Dimethylformamide catalyzes the thermal dehydration of aldoximes.[438] Heating an oxime with a Ru catalyst gives the nitrile.[439] Heating with the *Burgess reagent* [$Et_3N^{+-}SO_2N$-CO_2Me] in PEG is effective for this transformation.[440] Sulfuric acid impregnated silica gel[441] gives the nitrile, as does microwave irradiation of an oxime with tetrachloropyridine on alumina.[442] Aldehydes can be converted to oximes *in situ* and microwave irradiation on alumina[443] or with ammonium acetate[444] gives the nitrile. Solvent-free reactions are known.[445] The reaction is most successful when the H and OH are anti. Various alkyl and acyl derivatives of aldoximes (RCH=NOR,[446] RCH=NOCOR, $RCH=NOSO_2Ar$, etc.), also give nitriles, as do chlorimines (RCH=NCl; the latter with base treatment).[447] *N,N*-Dichloro derivatives of primary amines give nitriles upon pyrolysis: $RCH_2NCl_2 \rightarrow RCN$.[448]



Quaternary hydrazonium salts (derived from aldehydes) give nitriles when treated with ^-OEt[449] or DBU (see Reaction **17-13**):[450] as do dimethylhydrazones ($RCH=NNMe_2$), when treated with Et_2NLi and HMPA.[451] All these are methods of converting aldehyde derivatives to nitriles. For the conversion of aldehydes directly to nitriles, without isolation of intermediates (see Reaction **16-16**).

Hydroxylamines that have an α-proton are converted to nitrones when treated with a Mn–salen complex.[452]

Certain ketoximes can be converted to nitriles by the action of proton or Lewis acids.[453] Among these are oximes of α-diketones (illustrated above), α-keto acids, α-dialkylamino ketones, α-hydroxy ketones, β-keto ethers, and similar compounds.[454] These are fragmentation reactions, analogous to **17-25**. For example, α-dialkylamino ketoximes also give amines and aldehydes or ketones besides nitriles:[455]

The reaction that normally occurs on treatment of a ketoxime with a Lewis or proton acid is the *Beckmann rearrangement* (**18-17**); fragmentations are considered side reactions, often called "abnormal" or "second-order" *Beckmann rearrangements*.[456] Obviously, the substrates mentioned are much more susceptible to fragmentation than are ordinary ketoximes, since in each case an unshared pair is available to assist in removal of the group cleaving from the carbon. However, fragmentation is a side reaction even with ordinary ketoximes[457] and, in cases where a particularly stable carbocation can be cleaved, may be the main reaction:[458]

There are indications that the mechanism at least in some cases first involves a rearrangement and then cleavage. The ratio of fragmentation to *Beckmann rearrangement* of a series of oxime tosylates [RC(=NOTs)Me] was not related to the solvolysis rate but *was* related to the stability of R^+ (as determined by the solvolysis rate of the corresponding RCl), which showed that fragmentation did not take place in the rate-determining step.[459] It may be postulated then that the first step in the fragmentation and in the rearrangement is the same and that this is the rate-determining step. The product is determined in the second step:

17-30 Dehydration of Unsubstituted Amides

N,N- Dihydro- *C-* oxo-bielimination

Unsubstituted amides can be dehydrated to nitriles.[461] Phosphorous pentoxide is the most common dehydrating agent for this reaction, but many others, including $POCl_3$, PCl_5, CCl_4—Ph_3P,[462] HMPA,[463] LiCl with a Zr catalyst,[464] $MeOOCNSO_2NEt_3$ (the *Burgess reagent*),[465] $Me_2N{=}CHCl^+\ Cl^-$,[466] $AlCl_3/KI/H_2O$,[467] PPh_3/NCS,[468] oxalyl chloride/DMSO/ −78 °C[469] (*Swern* conditions, see Reaction **19-3**), *o*-iodoxybenzoic acid/Et_4NBr,[470] $PdCl_2$ in aq media,[471] TBAF and hydrosilanes,[472] Fe complexes,[473] and $SOCl_2$ have also been used.[474] Heating an amide with paraformaldehyde and formic acid gives the nitrile.[475] It is possible to convert an acid to the nitrile, without isolation of the amide, by heating its ammonium salt with the dehydrating agent,[476] or by other methods.[477] *N,N*-Disubstituted ureas give cyanamides (R_2N–CO–$NH_2 \rightarrow R_2N$–CN) when dehydrated with $CHCl_3$—NaOH under phase-transfer conditions.[478] Treatment of an amide with aq NaOH and ultrasound leads to the nitrile.[479]

N-Alkyl-substituted amides can be converted to nitriles and alkyl chlorides by treatment with PCl_5. This is called the *von Braun reaction* (not to be confused with the other von Braun reaction, **10-54**).

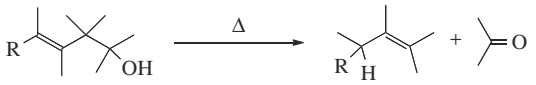
17-31 Conversion of N-Alkylformamides to Isonitriles (Isocyanides)

***CN*-Dihydro-*C*-oxo-bielimination**

Isocyanides (isonitriles) can be prepared by elimination of water from *N*-alkylformamides[480] with phosgene and a tertiary amine.[481] Other reagents, among them TsCl in quinoline, $POCl_3$ and a tertiary amine,[482] triflic anhydride/$(i\text{Pr})_2\text{NEt}$,[483] 2,4,6-Trichloro [1,3,5]triazine (cyanuric chloride, TCT), with microwave irradiation),[484] and $Ph_3P—CCl_4—Et_3N$[485] have also been employed. Formamides react with thionyl chloride (two sequential treatments) to give an intermediate that gives an isonitrile upon electrolysis in DMF with $LiClO_4$.[486]

A variation of this process uses carbodiimides,[487] which can be prepared by the dehydration of *N,N′*-disubstituted ureas with various dehydrating agents,[488] among which are TsCl in pyridine, $POCl_3$, PCl_5, P_2O_5–pyridine, and TsCl (with phase-transfer catalysis).[489] Hydrogen sulfide can be removed from the corresponding thioureas by treatment with HgO, NaOCl, or diethyl azodicarboxylate–triphenylphosphine.[490]



OS **V**, 300, 772; **VI**, 620, 751, 987. See also, OS **VII**, 27. For the carbodiimide/thiourea dehydration, see OS **V**, 555; **VI**, 951.

17.F.iv. Reactions in which C=O Bonds Are Formed

Many elimination-type reactions in which C=O bonds are formed were considered in Chapter 16, along with their more important reverse reactions (also see, Reactions **12-40** and **12-41**).

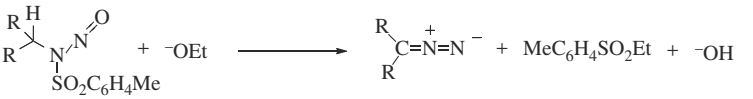
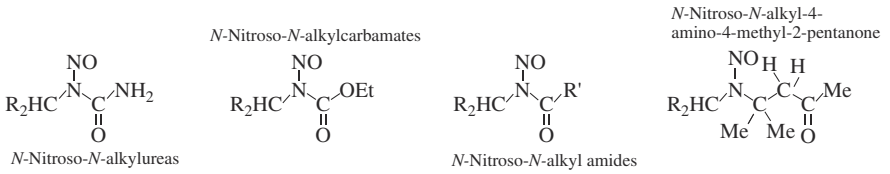
When pyrolyzed, β-hydroxy alkenes cleave to give alkenes and aldehydes or ketones.[491] Alkenes produced this way are quite pure, since there are no side reactions. The mechanism has been shown to be pericyclic, primarily by observations that the kinetics are first order[492] and that, for ROD, the deuterium appeared in the allylic position of the new alkene.[493] This mechanism is the reverse of that for the oxygen analogue of the ene synthesis (Reaction **16-54**). β-Hydroxyacetylenes react similarly to give the corresponding allenes and carbonyl compounds.[494] The mechanism is the same despite the linear geometry of the triple bonds.



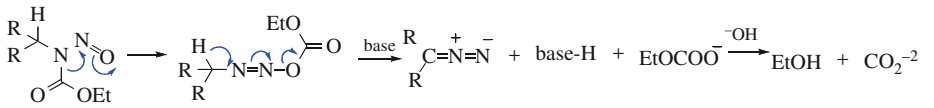
In a related reaction, pyrolysis of allylic ethers that contain at least one α hydrogen gives alkenes and aldehydes or ketones. The mechanism is also pericyclic[495]

17.F.v. Reactions in which N=N Bonds Are Formed



17-33 Eliminations to Give Diazoalkanes

_N_-Nitrosoamine-diazoalkane transformation



Various *N*-nitroso-*N*-alkyl compounds undergo elimination to give diazoalkanes.[496] One of the most convenient methods for the preparation of diazomethane involves base treatment of *N*-nitroso-*N*-methyl-*p*-toluenesulfonamide (illustrated above, with R = H).[497] However, other compounds commonly used are (base treatment is required in all cases):

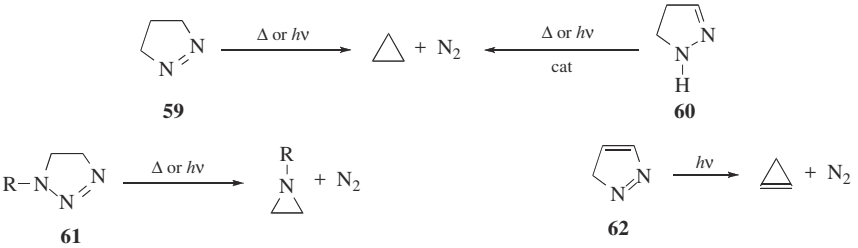
All of these compounds can be used to prepare diazomethane, although the sulfonamide, which is commercially available, is most satisfactory. *N*-Nitroso-*N*-methylcarbamate and *N*-nitroso-*N*-methylurea give good yields, but are highly irritating and carcinogenic.[498] For higher diazoalkanes, the preferred substrates are nitrosoalkylcarbamates.

Most of these reactions probably begin with a 1,3 nitrogen-to-oxygen rearrangement, followed by the actual elimination (illustrated for the carbamate):

OS **II**, 165; **III**, 119, 244; **IV**, 225, 250; **V**, 351; **VI**, 981.

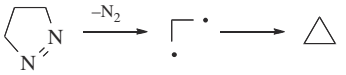
17.F.vi. Extrusion Reactions



We consider an *extrusion reaction*[499] to be one in which an atom or group Y connected to two other atoms X and Z is lost from a molecule, leading to a product in which X is bonded directly to Z.

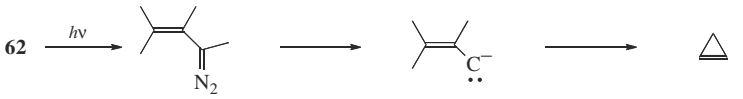
$$X{-}Y{-}Z \longrightarrow X{-}Z + Y$$

Reactions **14-32** and **17-20** also fit this definition. Reaction **17-28** does not fit the definition, but is often also classified as an extrusion reaction. A scale of extrusion facility has been developed, showing that the ease of extrusion of the common Y groups is in the order: $-N{=}N- > -COO- > -SO_2- > -CO-$.[500]



17-34 Extrusion of N_2 from Pyrazolines, Pyrazoles, and Triazolines

Azo-extrusion



[498] Searle, C.E. *Chem. Br.* ***1970****, 6*, 5.

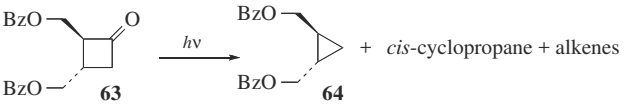
1-Pyrazolines (**59**) can be converted to cyclopropane and N_2 on photolysis[501] or pyrolysis.[502] The tautomeric 2-pyrazolines (**60**), which are more stable than **59**, also give the reaction, but in this case an acidic or basic catalyst is required, the function of which is to convert **60** to **59**.[503] In the absence of such catalysts, **60** does not react.[504] In a similar manner, triazolines (**61**) are converted to aziridines.[505] Side reactions are frequent with both **59** and **61**, and some substrates do not give the reaction at all. However, the reaction has proved synthetically useful in many cases. In general, photolysis gives better yields and fewer side reactions than pyrolysis with both **59** and **61**. 3*H*-Pyrazoles[506] (**62**) are stable to heat, but in some cases can be converted to cyclopropenes on photolysis,[507] although in other cases other types of products are obtained.



There is much evidence that the mechanism[508] of the 1-pyrazoline reactions generally involves diradicals, although the mode of formation and detailed structure (e.g., singlet vs triplet) of these radicals may vary with the substrate and reaction conditions. The reactions of the 3*H*-pyrazoles (**62**) have been postulated to proceed through a diazo compound that loses N_2 to give a vinylic carbene.[509]

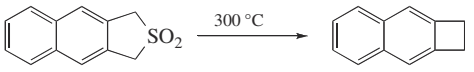
photolyzed to give **64**.[511] This reaction was used to synthesize tetra-*tert*-butyltetrahedrane, (**65**).[512]

The mechanism probably involves a *Norrish-type I cleavage* (Sec. 7.A.vii), loss of CO from the resulting radical, and recombination of the radical fragments.

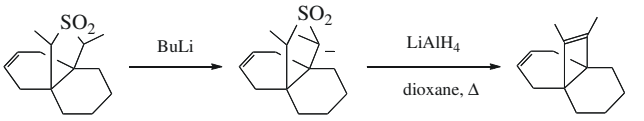
Certain lactones extrude CO_2 on heating or on irradiation (e.g., the pyrolysis of **66**).[513]



Decarboxylation of β-lactones (see **17-26**) may be regarded as a degenerate example of this reaction. Unsymmetrical diacyl peroxides (RCO—OO—COR′) lose two molecules of CO_2 when photolyzed in the solid state to give the product RR′.[514] Electrolysis was also used, but yields were lower. This is an alternative to the *Kolbe reaction* (**11-34**) (see also, **17-28** and **17-38**).

There are no OS references, but see OS **VI**, 418, for a related reaction.

17-36 Extrusion of SO_2



Sulfonyl-extrusion

In a reaction similar to **17-35**, certain sulfones, both cyclic and acyclic,[515] extrude SO_2 on heating or photolysis to give ring-contracted products.[516] An example is the preparation of naphtho(*b*)cyclobutene shown above.[517] In a different kind of reaction, five-membered

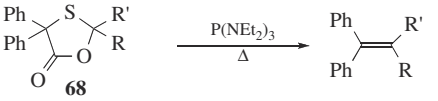
cyclic sulfones can be converted to cyclobutenes by treatment with butyllithium followed by $LiAlH_4$,[518] for example,

This method is most successful when both the α and α′ position of the sulfone bear alkyl substituents (see also, Reaction **17-20**). Treating four-membered ring sultams with $SnCl_2$ led to aziridine products via loss of SO_2.[519]

OS **VI**, 482.

17-37 The Story Synthesis



67

When cycloalkylidine peroxides (e.g., **60**) are heated in an inert solvent (e.g., decane), extrusion of CO_2 takes place; the products are the cycloalkane containing three carbon atoms less than the starting peroxide and the lactone containing two carbon atoms less[520] (the *Story synthesis*).[521] The two products are formed in comparable yields, usually ∼ 15–25% each. Although the yields are low, the reaction is useful because there are not many other ways to prepare large rings. The reaction is versatile, having been used to prepare rings of every size from 8 to 33 members.

Both dimeric and trimeric cycloalkylidine peroxides can be synthesized[522] by treatment of the corresponding cyclic ketones with H_2O_2 in acid solution.[523] The trimeric peroxide is formed first and is subsequently converted to the dimeric compound.[524]

4,4-Diphenyloxathiolan-5-ones (**68**) give good yields of the corresponding alkenes when heated with tris(diethylamino)phosphine.[525] This reaction is an example of a general type: alkene synthesis by twofold extrusion of X and Y from a molecule of the type **69**.[526] Other examples are photolysis of 1,4-diones[527] (e.g., **70**) and treatment of acetoxy sulfones [$RCH(OAc)CH_2SO_2Ph$] with Mg/EtOH and a catalytic amount of $HgCl_2$.[528] **68** can be prepared by the condensation of thiobenzilic acid [$Ph_2C(SH)COOH$] with aldehydes or ketones.

CHAPTER 18

Rearrangements

In a rearrangement reaction, a group moves from one atom to another in the same molecule.[1] Most are migrations from an atom to an adjacent one (called 1,2-shifts), but some are over longer distances. The group

that migrates (W) may move with its electron pair (these can be called *nucleophilic* or *anionotropic* rearrangements; the migrating group can be regarded as a nucleophile), without its electron pair (*electrophilic* or *cationotropic* rearrangements; in the case of migrating hydrogen, *prototropic* rearrangements), or with just one electron (radical rearrangements). The atom A is called the *migration origin* and B is the *migration terminus*. However, there are some rearrangements that do not lend themselves to neat categorization in this manner. Among these are those with cyclic transition states (Reactions **18-27**–**18-36**).

1

As will be seen, nucleophilic 1,2-shifts are much more common than electrophilic or free radical 1,2-shifts. The reason for this can be seen by a consideration of the transition states (or in some cases intermediates) involved. The transition state or intermediate for all three cases can be represented by **1**, in which the two-electron A—W bond overlaps with the orbital on atom B, which contains zero, one, and two electrons, in the case of nucleophilic, free radical, and electrophilic migration, respectively. The overlap of these orbitals gives rise to three new orbitals, which have an energy relationship similar to those in Section 2.K.i (one bonding and two degenerate antibonding orbitals). In a nucleophilic migration, where only two electrons are involved, both can go into the bonding orbital and **1** is a low-energy transition state, In a free radical or electrophilic migration, there are, respectively, three or four electrons that must be accommodated, and antibonding orbitals

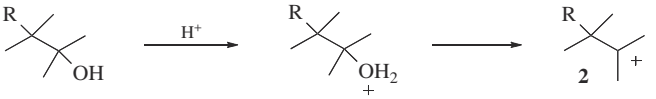
must be occupied. It is not surprising therefore that, when 1,2-electrophilic or free radical shifts are found, the migrating group W is usually aryl or some other group that can accommodate the extra one or two electrons and thus effectively remove them from the three-membered transition state or intermediate (see **41**).

In any rearrangement two possible modes of reaction can, in principle, be distinguished. In one of these, the group W becomes completely detached from A and may end up on the B atom of a different molecule (*intermolecular* rearrangement). In the other, W goes from A to B in the *same* molecule (*intramolecular* rearrangement), in which case there must be some continuing tie holding W to the A—B system, preventing it from coming completely free. Strictly speaking, only the intramolecular type fits our definition of a rearrangement, but the general practice, which is followed here, is to include under the title "rearrangement" all net rearrangements whether they are inter- or intramolecular. It is usually not difficult to tell whether a given rearrangement is inter- or intramolecular. The most common method involves the use of *cross over* experiments. In this type of experiment, rearrangement is carried out on a mixture of W—A—B and V—A—C, where V is closely related to W (say, methyl vs ethyl) and B to C. In an intramolecular process, only A—B—W and A—C—V are recovered, but if the reaction is intermolecular, then not only will these two be found, but also A—B—V and A—C—W.

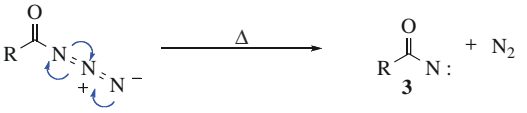
18.A. MECHANISMS



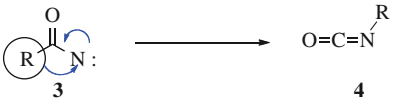
18.A.i. Nucleophilic Rearrangements[2]

Broadly speaking, such rearrangements consist of three steps, of which the actual migration is the second:

This process has been called the *Whitmore 1,2-shift*.[3] Since the migrating group carries the electron pair with it, the migration terminus B must be an atom with only six electrons in its outer shell (an open sextet). The first step therefore is creation of a system with an open sextet. Such a system can arise in various ways, but two of these are the most important:



1. *Formation of a Carbocation*: These can be formed in a number of ways (see Sec. 5. A.iii), but one of the most common methods is the acid treatment of an alcohol to give **2** from an intermediate oxonium ion. Such carbocations are subject to rearrangement to a more stable carbocation. These two steps are of course the same as the first two steps of the S_N1cA or the E1 reactions of alcohols.

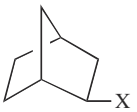


[2] Vogel, P. *Carbocation Chemistry*; Elsevier, NY, ***1985***, pp. 323–372; Shubin, V.G. *Top. Curr. Chem.* ***1984****, 116/117*, 267; Saunders, M.; Chandrasekhar, J.; Schleyer, P.v.R. in de Mayo, P. *Rearrangements in Ground and Excited States*, Vol. 1, Academic Press, NY, ***1980***, pp. 1–53; Kirmse, W. *Top. Curr. Chem.* ***1979****, 80,* 89. For reviews of rearrangements in vinylic cations, see Shchegolev, A.A.; Kanishchev, M.I. *Russ. Chem. Rev.* ***1981****, 50,* 553; Lee, C.C. *Isot. Org. Chem.* ***1980****, 5,* 1.

[3] It was first postulated by Whitmore, F.C. *J. Am. Chem. Soc.* ***1932****, 54,* 3274.

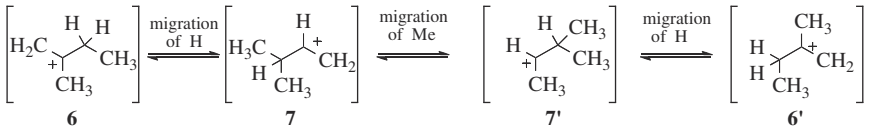
2. *Formation of a Nitrene*: The decomposition of acyl azides is one of several ways in which acyl nitrenes (**3**) are formed (see Sec. 5.E). After the migration has taken place, the atom at the migration origin (A) must necessarily have an open sextet. In the third step, this atom acquires an octet. In the case of carbocations, combinations with a nucleophile (rearrangement with substitution) and loss of H^+ (rearrangement with elimination). Constitute the most common third stop.

Although this mechanism is presented as taking place in three steps, and some reactions do take place in this way, in others the transformation is simultaneous. For example, in the nitrene example above, as the R migrates, an electron pair from the nitrogen moves into the C—N bond to give a stable isocyanate, (**4**). In this example, what are shown as the second and third steps are simultaneous. It is also possible for the second and third steps to be simultaneous even when the "third" step involves more than just a simple motion of a pair of electrons. Similarly, there are many reactions in which the first two steps are simultaneous; that is, there is no actual formation of a species (e.g., **2** or **3**). In these instances, it may be said that R assists in the removal of the leaving group, with migration of R and the removal of the leaving group taking place simultaneously. Many investigations have been carried out in attempts to determine, in various reactions, whether such intermediates as (**2**) or (**3**) actually form, or whether the steps are simultaneous (see, e.g., the discussions in Reaction **16-45** and Sec. 18.A.ii), but the difference between the two possibilities is often subtle, and the question is not always easily answered.[4]



Evidence for this mechanism is that rearrangements of this sort occur under conditions where previously carbocations have been encountered: S_N1 conditions, *Friedel–Crafts alkylation*, and so on. Solvolysis of neopentyl bromide leads to rearrangement products, and the rate increases with increasing ionizing power of the solvent, but is unaffected by concentration of base,[5] so that the first step is carbocation formation. The same compound under S_N2 conditions gave no rearrangement, but slowly gave only ordinary substitution. Thus with neopentyl bromide, formation of a carbocation leads only to rearrangement. Carbocations usually rearrange to more stable carbocations. Thus the direction of rearrangement is usually primary → secondary → tertiary. Neopentyl (Me_3CCH_2), neophyl ($PhCMe_2CH_2$), and norbornyl (e.g., **5**) type systems are especially prone to carbocation rearrangement

[4] The IUPAC designations depend on the nature of the steps. For the rules, see Guthrie, R.D. *Pure Appl. Chem.* ***1989****, 61,* 23, pp. 44–45.

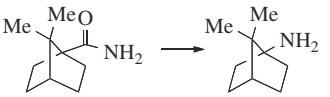


[5] Dostrovsky, I.; Hughes, E.D. *J. Chem. Soc.* ***1946***, 166.

reactions. It has been shown that the rate of migration increases with the degree of electron deficiency at the migration terminus.[6]

5

It was previously mentioned (Sec. 5.A.ii) that stable tertiary carbocations could be obtained, in solution, at very low temperatures. The NMR studies have shown that when these solutions are warmed, rapid migrations of hydride and of alkyl groups take place, resulting in an equilibrium mixture of structures.[7] For example, the *tert*-pentyl cation (**5**)[8] equilibrates as follows:



6 **7** **7'** **6'**

Carbocations that rearrange to give products of identical structure (**6**⇄**6′**, **7**⇄**7′**) are called *degenerate carbocations*. Such rearrangements are *degenerate rearrangements* and many examples are known.[9]

18.A.ii. The Actual Nature of the Migration

Most nucleophilic 1,2-shifts are intramolecular. The W group does not become free, but always remains connected in some way to the substrate. Apart from the evidence from cross-over experiments, the strongest evidence is that when the W group is chiral, the configuration is *retained* in the product. For example, (+)-PhCHMeCO$_2$H was converted to (−)-PhCHMeNH$_2$ by the *Curtius* (**18-14**), *Hofmann* (**18-13**), *Lossen* (**18-15**), and *Schmidt* (**18-16**) reactions.[10] In these reactions, the extent of retention varied from 95.8 to 99.6%. Retention of configuration in the migrating group has been shown many times since.[11] Another experiment demonstrating retention was the easy conversion of **8** to **9**.[11] Neither inversion nor racemization could take place at a bridgehead.

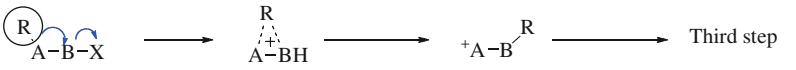
Using the simple example W-A-B, there is much evidence that retention of configuration usually occurs in W, and inversion never occurs.[12] However, this is not the state of affairs at A and B. In many reactions, of course, the structure of W—A—B is such that the product has only one steric possibility at A or B or both, and in most of these cases nothing can be learned. But in cases where the steric nature of A or B can be investigated, the results are mixed. It has been shown that either inversion or racemization can occur at A or B. One example is **10**, where the conversion proceeded with inversion (equivalent to inversion at B.[13] Inversion at A has been



shown in other cases.[14] However, in many other cases, racemization occurs at A or B or both.[15] It is not always necessary for the product to have two steric possibilities in order to investigate the stereochemistry at A or B. Thus, in most *Beckmann rearrangements* (**18-17**), only the group trans (usually called *anti*) to the hydroxyl group migrates, as illustrated by formation of **11**, which shows inversion at B.

This information tells us about the degree of concertedness of the three steps of the rearrangement. First, consider the migration terminus B in R—A—B—X. If racemization is found at B, it is probable that the first step takes place before the second and that a positively charged carbon (or other sextet atom) is present at B:

With respect to B this is an S_N1 type process. If inversion occurs at B, it is likely that the first two steps are concerted, that a carbocation is *not* an intermediate, and that the process is S_N2 like:

In this case, participation by R assists in removal of X in the same way that neighboring groups do (Sec. 10.C). Indeed, R *is* a neighboring group here. The only difference is that, in the case of the neighboring-group mechanism of nucleophilic substitution, R never becomes detached from A, while in a rearrangement the bond between R and A is broken.

In either case, the anchimeric assistance results in an increased rate of reaction. Of course, for such a process to take place, R must be in a favorable geometrical position (R and X antiperiplanar). Intermediate **12** may be a true intermediate, or there may only be a transition state, depending on what migrates. In certain cases of the S_N1 type process, it is possible for migration to take place with net retention of configuration at the migrating terminus because of conformational effects in the carbocation.[16]

A few conclusions may be summarized:

1. The S_N1 type process occurs mostly when B is a tertiary atom or has one aryl group and at least one other alkyl or aryl group. In other cases, the S_N2 type process is more likely. Inversion of configuration (indicating an S_N2 type process) has been shown for a neopentyl substrate by the use of the chiral neopentyl-1-*d* alcohol.[17] There is other evidence that neopentyl systems undergo rearrangement by a carbocation (S_N1 type) mechanism.[18]
2. The question as to whether **12** is an intermediate or a transition state has been much debated. When R is aryl or vinyl, then **12** is probably an intermediate and the migrating group lends anchimeric assistance[19] (see Sec. 10.C.i, category 3-preceding category 4 for resonance stabilization of this intermediate, when R is aryl). When R is alkyl, **12** is a protonated cyclopropane (edge- or corner protonated; see Sec. 15.B.iv). There is much evidence that in simple migrations of a methyl group, the bulk of the products formed do not arise from protonated cyclopropane *intermediates*. Evidence for this statement has already been given (Sec. 10.C.i, category 4c). Further evidence was obtained from experiments involving labeling.

Rearrangement of the neopentyl cation labeled with deuterium in the 1 position (**13**) gave only *tert*-pentyl products with the label in the 3 position (derived from **15**), though if **14** were an intermediate, the cyclopropane ring could just as well cleave the other way to give *tert*-pentyl derivatives labeled in the 4 position (derived from **16**).[20] Another experiment that led to the same conclusion was the generation, in several ways, of $Me_3C^{13}CH_2^+$. The only *tert*-pentyl products isolated were labeled in C-3, that is, $Me_2C^+—^{13}CH_2CH_3$ derivatives; no derivatives of $Me_2C^+—CH_2{}^{13}CH_3$ were found.[21]

Although the bulk of the products are not formed from protonated cyclopropane intermediates, there is considerable evidence that at least in 1-propyl systems, a small part of the product can in fact arise from such intermediates.[22] Among this evidence is the isolation of 10–15% cyclopropanes (mentioned in Sec. 10.C.i, category 4c). Additional evidence comes from propyl cations generated by diazotization of labeled amines ($CH_3CH_2CD_2^+$, $CH_3CD_2CH_2^+$, $CH_3CH_2{}^{14}CH_2^+$), where isotopic distribution in the products indicated that a small amount (∼5%) of the product had to be formed from protonated cyclopropane intermediates, for example,[23]

$$CH_3CH_2CD_2NH_2 \xrightarrow{HONO} -1\%\, C_2H_4D{-}CHD{-}OH$$

$$CH_3CD_2CH_2NH_2 \xrightarrow{HONO} -1\%\, C_2H_4D{-}CHD{-}OH$$

$$CH_3CH_2{}^{14}CH_2NH_2 \xrightarrow{HONO} -2\%\, {}^{14}CH_3CH_2CH_2OH + -2\%\, CH_3{}^{14}CH_2OH$$

Even more scrambling was found in trifluoroacetolysis of 1-propyl-1-^{14}C-mercuric perchlorate.[24] However, protonated cyclopropane intermediates accounted for <1% of the products from diazotization of labeled isobutylamine[25] and from formolysis of labeled 1-propyl tosylate.[26]

17 **18** **19**

It is likely that protonated cyclopropane transition states or intermediates are also responsible for certain non-1,2 rearrangements. For example, in superacid solution, the ions **17** and **19** are in equilibrium. It is not possible for these to interconvert solely by 1,2-alkyl or hydride shifts unless primary carbocations, which are highly unlikely, are intermediates. However, the reaction can be explained[27] by postulating that (in the forward reaction) it is the 1,2-bond of the intermediate or transition state **18** that opens up rather than the 2,3-bond, which is the one that would open if the reaction were a normal 1,2-shift of a methyl group. In this case, opening of the 1,2-bond produces a tertiary cation, while opening of the 2,3-bond would give a secondary cation. (In the reaction **19** → **17**, it is of course the 1,3-bond that opens).

3. There has been much discussion of H as the migrating group. There is no conclusive evidence that **10** in this case is or is not a true intermediate, although both positions have been argued (see Sec. 10.C.i, category 4c).

The stereochemistry at the migration origin A is less often involved, since in most cases it does not end up as a tetrahedral atom; but when there is inversion here, there is an S_N2 type process at the beginning of the migration. This may or may not be accompanied by an S_N2 process at the migration terminus B:

In some cases, it has been found that, when H is the migrating species, the configuration at A may be *retained*.[28]

There is evidence that the configuration of the molecule may be important even where the leaving group is gone long before migration takes place. For example, the 1-adamantyl cation (**20**) does not equilibrate intramolecularly, even at temperatures up to 130 °C,[29] though open-chain (e.g., **6**-**6′**) and cyclic tertiary carbocations undergo such equilibration at 0 °C or below. On the basis of this and other evidence, it has been concluded that for a 1,2-shift of hydrogen or methyl to proceed as smoothly as possible, the vacant *p* orbital of the carbon bearing the positive charge and the sp^3 orbital carrying the migrating group must be coplanar,[29] which is not possible for **20**.

18.A.iii. Migratory Aptitudes[30]

In many reactions, there is no question about which group migrates. For example, in the *Hofmann*, *Curtius*, and similar reactions there is only one possible migrating group in each molecule, and one can measure migratory aptitudes only by comparing the relative rearrangement rates of different compounds. In other instances, there are two or more potential migrating groups, but which migrates is settled by the geometry of the molecule. The *Beckmann rearrangement* (Reaction **18-17**) provides an example. As seen in the formation of **11**, only the group trans to the OH migrates. In compounds whose geometry is not restricted in this manner, there still may be eclipsing effects (see Sec. 17.C), so that the choice of migrating group is largely determined by which group is in the right place in the most stable conformation of the molecule.[31] However, in some reactions, especially the W*agner–Meerwein* (**18-1**) and the *pinacol* (**18-2**) rearrangements, the molecule may contain several groups that, geometrically at least, have approximately equal chances

[31] See Cram, D.J. in Newman, M.S. *Steric Effects in Organic Chemistry, Wiley, NY,* ***1956***, pp. 270–276. For an interesting example, see Nickon, A.; Weglein, R.C. *J. Am. Chem. Soc.* ***1975****, 97,* 1271.

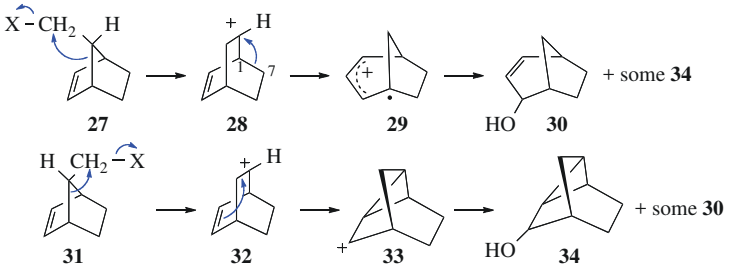
of migrating, and these reactions have often been used for the direct study of relative migratory aptitudes. In the *pinacol rearrangement*, there is the additional question of which OH group leaves and which does not, since a group can migrate only if the OH group on *the other* carbon is lost.

We deal with the second question first. To study this question, the best type of substrate to use is one of the form $R_2C(OH)—C(OH)R'_2$, since the only thing that determines migratory aptitude is which OH group comes off. Once the OH group is gone, the migrating group is determined. As might be expected, the OH that leaves is the one whose loss gives rise to the more stable carbocation. Thus 1,1-diphenylethanediol (**21**) gives diphenylacetaldehyde (**22**), not phenylacetophenone (**23**). Obviously, it does not matter in this case whether phenyl has a greater inherent migratory aptitude than hydrogen or not. Only the hydrogen can migrate because **24** is not formed. Remember that carbocation stability is enhanced by groups in the order aryl > alkyl > hydrogen, and this normally determines which side loses the OH group. However, exceptions are known, and which group is lost may depend on the reaction conditions (e.g., see the reaction of **59**).

In order to answer the question about inherent migratory aptitudes, the obvious type of substrate to use (in the pinacol rearrangement) is R′RC(OH)—COH)RR′, since the same carbocation is formed no matter which OH leaves, and it would seem that a direct comparison of the migratory tendencies of R and R′ is possible. On closer inspection, however, it is clear that several factors are operating. Apart from the question of possible conformational effects, already mentioned, there is also the fact that whether the group R or R′ migrates is determined not only by the relative inherent migrating abilities of R and R′, but also by whether the group that does *not* migrate is better at stabilizing the positive charge that will now be found at the migration origin.[32] Thus, migration of R gives rise to the cation $R'C^+(OH)CR_2R_2'$, while migration of R′ gives the cation $R^+C(OH)CRR_2'$ and these cations have different stabilities. It is possible that in a given case R might be found to migrate less than R′, not because it actually has a lower inherent migrating tendency, but because it is much

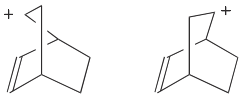
better at stabilizing the positive charge. In addition to this factor, the migrating ability of a group is also related to its capacity to render anchimeric assistance to the departure of the

[32] See McCall, M.J.; Townsend, J.M.; Bonner, W.A. *J. Am. Chem. Soc.* ***1975****, 97,* 2743; Brownbridge, P.; Hodgson, P.K.G.; Shepherd, R.; Warren, S. *J. Chem. Soc. Perkin Trans. 1* ***1976***, 2024.



nucleofuge. An example of this effect is the decomposition of tosylate (**25**) where only the phenyl group migrates, while in acid treatment of the corresponding alkene (**26**), there is competitive migration of both methyl and phenyl (in these reactions ^{14}C labeling is necessary to determine which group has migrated).[33] Both **25** and **26** give the same carbocation; the differing results must be caused by the fact that in **25** the phenyl group can assist the leaving group, while no such process is possible for **26**. This example clearly illustrates the difference between migration to a relatively free terminus and one that proceeds with the migrating group lending anchimeric assistance.[34]

Therefore, it is not surprising that clear-cut answers as to relative migrating tendencies are not available. More often than not migratory aptitudes are in the order aryl > alkyl, but exceptions are known, and the position of hydrogen in this series is often unpredictable. In some cases, migration of hydrogen is preferred to aryl migration; in other cases, migration of alkyl is preferred to that of hydrogen. Mixtures are often found, and the isomer that predominates often depends on conditions. For example, the comparison between methyl and ethyl has been made many times in various systems, and in some cases methyl migration and in others ethyl migration has been found to predominate.[35] However, it can be said that among aryl migrating groups, electron-donating substituents in the para and meta positions increase the migratory aptitudes, while the same substituents in the ortho positions decrease them. Electron-withdrawing groups decrease migrating ability in all positions. The following are a few of the relative migratory aptitudes determined for aryl groups:[36] *p*-anisyl, 500; *p*-tolyl, 15.7; *m*-tolyl, 1.95; phenyl, 1.00; *p*-chlorophenyl, 0.7; *o*-anisyl, 0.3. For the *o*-anisyl group, the poor migrating ability probably has a steric cause, while for the others there is a fair correlation with activation or deactivation of electrophilic aromatic substitution, which is what the process is with respect to the benzene ring. It has been reported that at least in certain systems acyl groups have a greater migratory aptitude than alkyl groups.[37]



18.A.iv. Memory Effects[38]

Solvolysis of the endo bicyclic compound (**27**, X = ONs, see Sec. 10.G.iii, or Br) gave mostly the bicyclic allylic alcohol (**30**), along with a smaller amount of the tricyclic alcohol (**34**), while solvolysis of the exo isomers, (**31**), gave mostly **34**, with smaller amounts of **30**.[39] Note that endo and exo here refers to the position of the XCH_2 group over the C=C unit or opposite the C=C unit, respectively. The two isomers gave entirely different ratios of products, although the carbocation initially formed seems to be the same for each (marked **28** and **32** for convenience). With **28**, a second rearrangement (a shift of the 1,7 bond) follows to give **29**, while with **32**

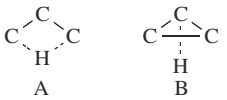
[38] For a review, see Berson, J.A. *Angew. Chem. Int. Ed.* ***1968****, 7,* 779.
[39] Berson, J.A.; Poonian, M.S.; Libbey, W.J. *J. Am. Chem. Soc.* ***1969****, 91*, 5567; Berson, J.A.; Donald, D.S.; Libbey, W.J. *J. Am. Chem. Soc.* ***1969****, 91,* 5580; Berson, J.A.; Wege, D.; Clarke, G.M.; Bergman, R.G. *J. Am. Chem. Soc.* ***1969****, 91*, 5594, 5601.

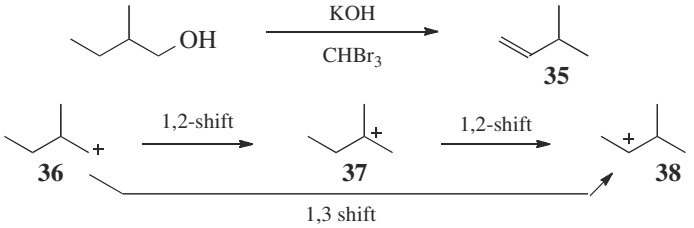
an intramolecular addition of the positive carbon to the double bond gives **33**. It seems as if **28** and **32** "remember" how they were formed before they go on to give the second step. Such effects are called *memory effects* and other such cases are known.[40] The causes of these effects are not well understood, although there has been much discussion. One possible cause is differential solvation of the apparently identical ions **28** and **32**. Other possibilities are (1) that the ions have geometrical structures that are twisted in opposite senses (e.g., a twisted **32** might have its positive



carbon closer to the double bond than a twisted **28**); (*2*) that ion pairing is responsible[41]; and (3) that nonclassical carbocations are involved.[42] One possibility that has been ruled out is that steps **27** → **28** → **29** and **31** → **32** → **33** are concerted, so that **28/32** never exist at all. This possibility has been excluded by several kinds of evidence, including the fact that **27** gives not only **30**, but also some **34**; and **31** gives some **30** along with **34**. This means that some of the **28** and **32** ions interconvert, a phenomenon known as *leakage*.

18.B. LONGER NUCLEOPHILIC REARRANGEMENTS

The question as to whether a group can migrate with its electron pair from A to C in W—A—B—C or over longer distances has been much debated. Although claims have been made that alkyl groups can migrate in this way, the evidence is that such migration is extremely rare, if it occurs at all. One experiment that demonstrated this was the generation of the 3,3-dimethyl-1-butyl cation ($Me_3CCH_2CH_2^+$). If 1,3-methyl migrations are possible, this cation would appear to be a favorable substrate, since such a migration would convert a primary cation into the tertiary 2-methyl-2-pentyl cation ($Me_2C^+CH_2CH_2CH_3$), while the only possible 1,2 migration (of hydride) would give only a secondary cation. However, no products arising from the 2-methyl-2-pentyl cation were found, the only rearranged products being those formed by the 1,2-hydride migration.[43] 1,3-Migration of bromine has been reported.[44]



[40] See Collins, C.J. *Acc. Chem. Res.* ***1971****, 4,* 315; Collins, J.A.; Glover, I.T.; Eckart, M.D.; Raaen, V.F.; Benjamin, B.M.; Benjaminov, B.S. *J. Am. Chem. Soc.* ***1972****, 94*, 899; Svensson, T. *Chem. Scr.* ***1974****, 6,* 22.

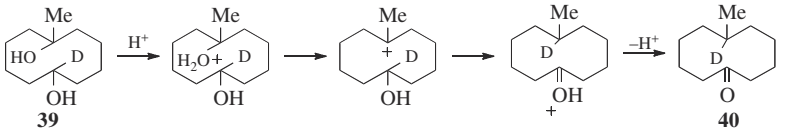
[43] Skell, P.S.; Reichenbacher, P.H. *J. Am. Chem. Soc.* ***1968****, 90,* 2309.
[44] Reineke, C.E.; McCarthy, Jr., J.R. *J. Am. Chem. Soc.* ***1970****, 92,* 6376; Smolina, T.A.; Gopius, E.D.; Gruzdneva, V.N.; Reutov, O.A. *Doklad. Chem.* ***1973****, 209,* 280.

Most of the debate over the possibility of 1,3-migrations has concerned not methyl or bromine but 1,3-hydride shifts.[45] Many instances have been found of *apparent* 1,3-hydride shifts, but the question is whether they are truly direct hydride shifts or whether they occur by another mechanism. There are at least two ways in

A B



which indirect 1,3-hydride shifts can take place: (1) by successive 1,2-shifts or (2) through the intervention of protonated cyclopropanes (see Sec. 18.A.ii, category 2). A direct 1,3-shift would have transition state **A**, while the transition state for a 1,3-shift involving a protonated cyclopropane intermediate would resemble **B**. The evidence is that most reported 1,3-hydride shifts are actually the result of successive 1,2-migrations,[46] but in some cases small amounts of products cannot be accounted for in this way. The reaction of 2-methyl-1-butanol with KOH and bromoform gave a mixture of alkenes, nearly all of which could have arisen from simple elimination or 1,2-shifts of hydride or alkyl. However, 1.2% of the product was **35**.[47] Hypothetically, **35** could have arisen from a 1,3 shift (direct or through a protonated cyclopropane) or from two successive 1,2-shifts:

However, the same reaction applied to 2-methyl-2-butanol gave no **35**, which demonstrated that **38** was not formed from **37**. The conclusion made was that **38** was formed directly from **36**. This experiment does not answer the question as to whether **38** was formed by a direct shift or through a protonated cyclopropane, but from other evidence[48] it appears that 1,3-hydride shifts that do not result from successive 1,2-migrations usually take place through protonated cyclopropane intermediates, which (as seen in Sec. 18.A.ii, category 2) account for only a small percentage of the product in any case. However, there is evidence that direct 1,3-hydride shifts by way of **A** (see above) may take place in superacid solutions.[49] Although direct nucleophilic rearrangements over distances >1,2 are rare (or perhaps nonexistent) when the migrating atom or group must move along a chain, this is not so for a shift across a ring of 8–11 members. Many such transannular rearrangements are known[50] (see Sec. 4.Q.ii): the mechanism for the

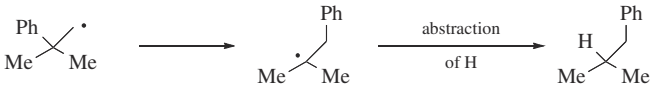
conversion of **39** to **40** is shown.[51]



Note that the *methyl* group does not migrate in this system. *It is generally true that alkyl groups do not undergo transannular migration*.[52] In most cases, it is the hydride that undergoes this type of migration, though a small amount of phenyl migration has also been shown.[53]

18.C. FREE RADICAL REARRANGEMENTS[54]

1,2-Free radical rearrangements are much less common than the nucleophilic type previously considered, for the reasons mentioned in the introductory Section 18.A. Where they do occur, the general pattern is similar. There must first be generation of a free radical, and then the actual migration in which the migrating group moves with one electron:

Finally, the new free radical will undergo a further reaction to generate a neutral molecule. The order of radical stability leads to a prediction that here too, as with carbocation rearrangements, migrations should be in the order primary → secondary → tertiary, and that the logical place to look for them should be in neopentyl and neophyl systems. The most common way of generating free radicals for the purpose of detection of rearrangements is by decarbonylation of aldehydes (Reaction **14-32**). In this manner, it was found that neophyl radicals *do* undergo rearrangement.[55] Thus, $PhCMe_2CH_2CHO$ treated with di-*tert*-butyl peroxide gave about equal amounts of the normal product $PhCMe_2CH_3$ and the product arising from migration of phenyl[56]:

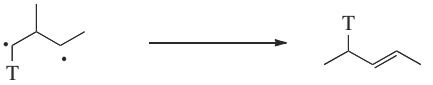
Many other cases of free radical migration of aryl groups have been found.[57] Intramolecular radical rearrangements are known.[58] The C-4 radicals of α-and β-thujone undergo two distinct rearrangement reactions, and it has been proposed that these could serve as simultaneous but independent radical clocks.[59]

A 1,2-shift has been observed in radicals bearing an OCOR group at the β-carbon where the oxygen group migrates as shown in the interconversion of **41** and **42**. This has been proven by ^{18}O isotopic labeling experiments[60] and other mechanistic explorations.[61] A similar rearrangement was observed with phosphatoxy alkyl radicals (e.g., as **43**.[62] A 1,2-shift of hydrogen atoms has been observed in aryl radicals.[63]

Note that the extent of migration is much less than with corresponding carbocations: Thus in the example given, there was only ∼50% migration, whereas the carbocation would have given much more. Also noteworthy is that there was no migration of the methyl group. In general, it may be said that free radical migration of alkyl groups does not occur at ordinary temperatures. *Many attempts have been made to detect such migration on the traditional neopentyl and bornyl types of substrates. However, alkyl migration is not observed, even in substrates where the corresponding carbocations undergo facile rearrangement*.[64] Another type of migration that is very common for carbocations, but not observed for free radicals, is 1,2-migration of hydrogen. We confine ourselves to a few examples of the lack of migration of alkyl groups and hydrogen:



1. 3,3-Dimethylpentanal ($EtCMe_2CH_2CHO$) gave no rearranged products on decarbonylation.[65]
2. Addition of RSH to norbornene gave only *exo*-norbornyl sulfides, though **44** is an intermediate, and the corresponding carbocation cannot be formed without rearrangement.[66]

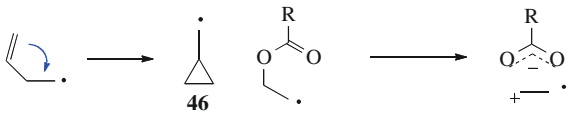
3. The cubylcarbinyl radical did not rearrange to the 1-homocubyl radical, though doing so would result in a considerable decrease in strain.[67]
4. It was shown[68] that no rearrangement of isobutyl radical to *tert*-butyl radical, which would involve the formation of a more stable radical by a hydrogen shift, took place during the chlorination of isobutane.

However, 1,2-migration of alkyl groups has been shown to occur in certain *diradicals*.[69] For example, the following rearrangement has been established by tritium labeling.[70]

In this case, the fact that migration of the methyl group leads directly to a compound in which all electrons are paired undoubtedly contributes to the driving force of the reaction.

The fact that aryl groups migrate, but alkyl groups and hydrogen generally do not, leads to the proposition that **45**, in which the odd electron is not found in the three-membered ring, may be an intermediate. There has been much controversy on this point, but the bulk of the evidence indicates that **45** is a transition state, not an intermediate.[71] Among the evidence is the failure to observe **45** either by ESR[72] or CIDNP.[73] Both of these techniques can detect free radicals with extremely short lifetimes (Sec. 5.C.i).[74]



45

In addition, aryl, vinylic[75] and acetoxy groups[76] also migrate. Vinylic groups migrate via a cyclopropylcarbinyl radical intermediate (**46**),[77] while the migration of acetoxy groups may involve the charge-separated structure shown.[78] Thermal isomerization of 1-(3-butenyl)cyclopropane at 415 °C leads to bicyclo[2.2.1]heptane.[79] Migration has been

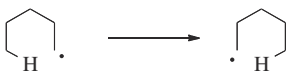
observed for chloro (and to a much lesser extent bromo) groups.

46

For example, in the reaction of $Cl_3CCH{=}CH_2$ with bromine under the influence of peroxides, the products were 47% $Cl_3CCHBrCH_2Br$ (the normal addition product) and 53% $BrCCl_2CHClCH_2Br$, which arose by rearrangement:



In this particular case, the driving force for the rearrangement is the particular stability of dichloroalkyl free radicals.[80] It has been shown that the 1,2-migration of Cl readily occurs if the migration origin is tertiary and the migration terminus is primary.[81] Migration of Cl and Br could take place by a transition state in which the odd electron is accommodated in a vacant *d* orbital of the halogen.

Migratory aptitudes have been measured for the phenyl and vinyl groups, and for three other groups, using the system $RCMe_2CH_2^{\bullet} \rightarrow Me_2OC^{\bullet}CH_2R$. These were found to be in the order $R = H_2C{=}CH_2 > Me_3CC{=}O > Ph > Me_3CC{\equiv}C > CN$.[82]

In summary, 1,2 free radical migrations are much less prevalent than the analogous carbocation processes, and are important only for aryl, vinylic, acetoxy, and halogen migrating groups. The direction of migration is normally toward the more stable radical, but "wrong-way" rearrangements are also known.[83]

Despite the fact that hydrogen atoms do not migrate 1,2, longer free radical migrations of hydrogen are known.[84] The most common are 1,5-shifts, but 1,6 and longer shifts have also been found (see Reaction **18-29**). The possibility of 1,3-hydrogen shifts has been much investigated, but it is not certain if any actually occur. If they do they are rare, presumably because the most favorable geometry for $C\cdots H\cdots C$ in the transition state is linear and this geometry cannot be achieved in a 1,3-shift. 1,4-Shifts are definitely known, but are still not very common. These long shifts are best regarded as internal abstractions of hydrogen (for Reactions, see **14-6** and **18-40**):

Transannular shifts of hydrogen atoms have also been observed.[85]

18.D. CARBENE REARRANGEMENTS[86]

Carbenes can rearrange to alkenes in many cases.[87] A 1,2-hydrogen shift leads to an alkene, and this is often competitive with insertion reactions.[88] Benzylchlorocarbene (**47**) rearranges via a 1,2-hydrogen shift to give the alkene.[89] Similarly, carbene **48** rearranges to alkene **49**, and replacement of H on the α-carbon with D showed a deuterium isotope effect of ∼5.[90] Vinylidene carbene ($H_2C{=}C{:}$) rearranges to acetylene.[91] Rearrangement of alkylidene carbene (**50**) has been calculated to give the highly unstable cyclopentyne (**51**), which cannot be isolated, but can give a [2 + 2] cycloaddition product (Reaction **15-63**) when generated in the presence of a simple alkene.[92] The spiro carbenes undergo rearrangement reactions.[93]

47 **48** **49** **50** **51**

18.E. ELECTROPHILIC REARRANGEMENTS[94]

Rearrangements in which a group migrates without its electrons are rarer than the two kinds previously considered, but the general principles are the same. A carbanion (or other negative ion) is created first, and the actual rearrangement step involves migration of a group without its electrons:

The product of the rearrangement may be stable or may react further, depending on its nature (see also, Reaction **18-2**). An *ab initio* study predicts that a [1,2]-alkyl shift in alkyne anions should be facile.[95]

18.F. REACTIONS

The reactions in this chapter are classified into three main groups and 1,2-shifts are considered first. Within this group, reactions are classified according to (1) the identity of the substrate atoms A and B and (2) the nature of the migrating group W. The cyclic

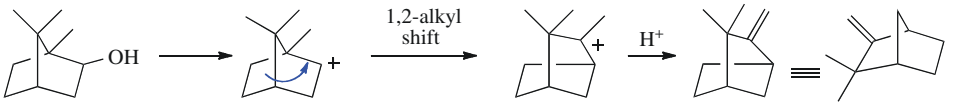
rearrangements are in the second group. The third group consists of rearrangements that cannot be fitted into either of the first two categories.



Reactions in which the migration terminus is on an aromatic ring have been treated under aromatic substitution. These are Reactions **11-27**–**11-32**, **11-36**, **13-30**-**13-32**, and, partially, **11-33**, **11-38**, and **11-39**. Double-bond shifts have also been treated in other chapters, although they may be considered rearrangements (Sec. 8.A and Reactions **12-**4, and **12-2**). Other reactions that may be regarded as rearrangements are the *Pummerer* (**19-83**) and *Willgerodt* (**19-84**) reactions.

18.F.i. 1,2-Rearrangements

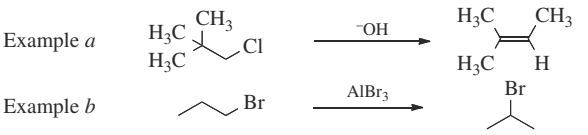
A. Carbon-to-Carbon Migrations of R, H, and Ar

18-1 Wagner–Meerwein and Related Reactions

1/Hydro,1/hydroxy-(2/→1/alkyl)- *migro-* elimination, and so on

Isoborneol **52** **53** Camphene

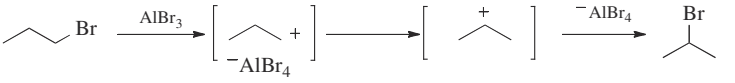
Wagner-Meerwein rearrangements were first discovered in reactions of bicyclic terpenes, and most of the early development of this reaction was with these compounds.[96] An example is the conversion of isoborneol to camphene. It fundamentally involves a 1,2-alkyl shift of an intermediate carbocation, (e.g., **52** → **53**). When alcohols are treated with acids, simple substitution (e.g., Reaction **10-48**) or elimination (Reaction **17-1**) usually accounts for most or all of the products. But in many cases, especially where two or three alkyl or aryl groups are on the β carbon, some or all of the product is rearranged. These rearrangements have been called *Wagner–Meerwein rearrangements*, although this term is nowadays reserved for relatively specific transformations (e.g., isoborneol to camphene and related reactions). As pointed out previously, the carbocation that is a direct product of the rearrangement must stabilize itself, and most often it does this by the loss of a hydrogen β to it, so the rearrangement product is usually an alkene.[97] If there is a choice of protons, *Zaitsev's rule* (Sec. 17.A.i, category 3) governs the direction, as expected. Sometimes a different positive group is lost instead of a proton. Less often, the new carbocation reacts with a nucleophile instead of losing a proton. The nucleophile may be the water that is the original leaving group, in which case the product is a rearranged alcohol; or it may be some other species present (solvent, added nucleophile, etc.).



Rearrangement is usually predominant in neopentyl and neophyl types of substrates, and with these types normal nucleophilic substitution is difficult (normal elimination is of course impossible). Under S_N2 conditions, substitution is extremely slow[98]; and under S_N1 conditions, carbocations are formed that rapidly rearrange. However, free radical

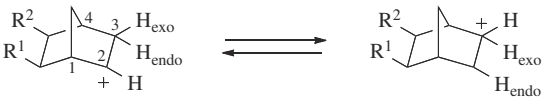
[96] See Hogeveen, H.; van Kruchten, E.M.G.A. *Top. Curr. Chem.* ***1979****, 80*, 89; Arbuzov, B.A.; Isaeva, Z.G. *Russ. Chem. Rev.* ***1976****, 45,* 673; Banthorpe, D.V.; Whittaker, D. *Q. Rev. Chem. Soc.* ***1966****, 20*, 373.

[97] See Kaupp, G. *Top. Curr. Chem.* ***1988****, 146,* 57.



[98] See, however, Lewis, R.G.; Gustafson, D.H.; Erman, W.F. *Tetrahedron Lett.* ***1967***, 401; Paquette, L.A.; Philips, J.C. *Tetrahedron Lett.* ***1967***, 4645; Anderson, P.H.; Stephenson, B.; Mosher, H.S. *J. Am. Chem. Soc.* ***1974***, *96*, 3171.

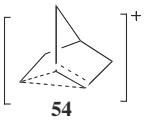
substitution, unaccompanied by rearrangement, can be carried out on neopentyl systems, although, as seen previously (Sec. 18.C), neophyl systems undergo rearrangement as well as substitution.



Examples of carbocation rearrangements are found in simpler systems (e.g., neopentyl chloride, example *a*) and even 1-bromopropane (example *b*). These examples illustrate the following points:

1. Hydride ion can migrate. In example *b*, it was hydride that shifted, not bromine:

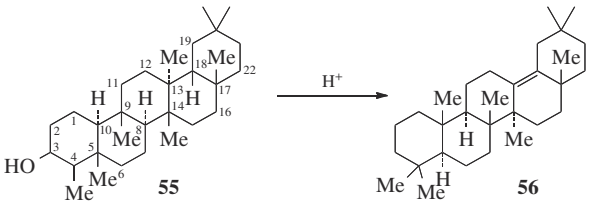
2. The leaving group does not have to be H_2O, but can be any departing species whose loss creates a carbocation, including N_2 from aliphatic diazonium ions[99] (see the section on leaving groups in nucleophilic substitution in Sec. 10.A.ii, category 1). Rearrangement may follow when the carbocation is created by addition of a proton or other positive species to a double bond.
3. Example *b* illustrates that the last step can be substitution instead of elimination.
4. Example *a* illustrates that the new double bond is formed in accord with *Zaitsev's rule*.



2-Norbornyl cations (see **52**), besides displaying the 1,2-shifts of a CH_2 group previously illustrated for the isoborneol → camphene conversion, are also prone to rapid hydride shifts from the 3 to the 2 position (known as 3,2-shifts). These 3,2-shifts usually take place from the exo side[100]; that is, the 3-exo hydrogen migrates to the 2-exo position.[101] This stereoselectivity is analogous to the behavior previously seen for norbornyl systems, namely, that nucleophiles attack norbornyl cations from the exo side (Sec. 10.C.i, category 4) and that addition to norbornenes is also usually from the exo direction (Sec. 15.B.iii).

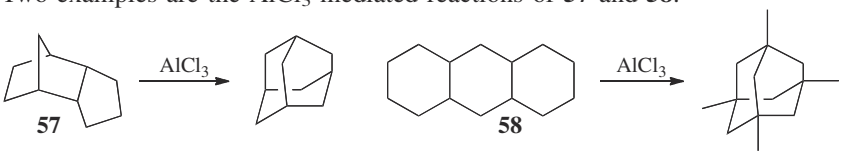
For rearrangements of alkyl carbocations, the direction of rearrangement is usually toward the most stable carbocation (or radical), which is tertiary > secondary > primary, but rearrangements in the other direction have also been found,[102] and the product is

[99] See, in Patai, S. *The Chemistry of the Amino Group*, Wiley, NY, ***1968***, the articles by White, E.H.; Woodcock, D.J. pp. 407–497 (473–483) and by Banthorpe, D.V. pp. 585–667 (pp. 586–612).
[100] See Berson, J.A.; Hammons, J.H.; McRowe, A.W.; Bergman, R.G.; Remanick, A.; Houston, D. *J. Am. Chem. Soc.* ***1967****, 89,* 2590.
[101] For an example of a 3,2-endo shift, see Wilder, Jr., P.; Hsieh, W. *J. Org. Chem.* ***1971****, 36*, 2552.
[102] See Cooper, C.N.; Jenner, P.J.; Perry, N.B.; Russell-King, J.; Storesund, H.J.; Whiting, M.C. *J. Chem. Soc. Perkin Trans. 2* ***1982***, 605.



sometimes a mixture corresponding to an equilibrium mixture of the possible carbocations. The *Wagner–Meerwein rearrangement* has been observed for a secondary to a secondary carbocation rearrangement, leading to some controversy. Winstein[103] described norbornyl cations in terms of the resonance structures represented by the nonclassical ion **54**.[104] This view was questioned, primarily by Brown,[105] who suggested that the facile rearrangements could be explained by a series of fast *1,3-Wagner–Meerwein shifts*.[106] There is considerable evidence, however, that *the norbornyl cation rearranges with σ participation*,[107] and there is strong NMr evidence for the nonclassical ion in superacids at low temperatures.[108]

54



As alluded to above, the term "*Wagner–Meerwein rearrangement*" is not precise. Some use it to refer to all the rearrangements in this section and in Reaction **18-2**. Others use it only when an alcohol is converted to a rearranged alkene. Many use the term only for rearrangements that involve a nonclassical carbocation intermediate. Terpene chemists call the migration of a methyl group the *Nametkin rearrangement*. The term *retropinacol rearrangement* is often applied to some or all of these. Fortunately, this disparity in nomenclature does not seem to cause much confusion. Catalytic asymmetric *Wagner–Meerwein shifts* have been observed.[109] An asymmetric, Pd catalyzed *Wagner–Meerwein shift* has been reported with allenic alcohols.[110]

Several of these rearrangements sometimes occur in one molecule, either simultaneously or in rapid succession. A spectacular example is found in the triterpene series. Friedelin is a triterpenoid ketone found in cork. Reduction gives 3β-friedelanol (**55**). When this compound is treated with acid, 13(18)-oleanene (**56**) is formed.[111] In this case, *seven* 1,2-shifts take place. Loss of H_2O from position 3 leaves a positive charge, and

Me

the following shifts occur: hydride from 4 to 3; methyl from 5 to 4; hydride from 10 to 5; methyl from 9 to 10; hydride from 8 to 9; methyl from 14 to 8; and methyl from 13 to 14. This leaves a positive charge at position 13, which is stabilized by loss of the proton at the 18 position to give **56**. All these shifts are stereospecific, the group always migrating on the side of the ring system on which it is located; that is, a group above the "plane" of the ring system (indicated by a solid line in **55**) moves above the plane, and a group below the plane (dashed line) moves below it. It is probable that the seven shifts are not all concerted, although some of them may be, for intermediate products can be isolated.[112] As an illustration of point 2 (see above), it may be mentioned that friedelene, derived from dehydration of **55**, also gives **56** on treatment with acid.[113]

Some alkanes undergo *Wagner–Meerwein rearrangements* if treated with Lewis acids and a small amount of initiator. An interesting application of this reaction is the conversion of tricyclic molecules to adamantane and its derivatives.[114] It has been found that *all* tricyclic alkanes containing 10 carbons are converted to adamantane by treatment with a Lewis acid, (e.g., $AlCl_3$). If the substrate contains $>$ 10 carbons, alkyl-substituted adamantanes are produced. The IUPAC name for these reactions is *Schleyer adamantization*. Two examples are the $AlCl_3$-mediated reactions of **57** and **58**.

57 **58**

If 14 or more carbons are present, the product may be diamantane or a substituted diamantane.[115] These reactions are successful because of the high thermodynamic stability of adamantane, diamantane, and similar diamond-like molecules. The most stable of a set of C_nH_m isomers (called the *stabilomer*) will be the end product if the reaction reaches equilibrium.[116] Best yields are obtained by the use of "sludge" catalysts[117] (i.e., a mixture of AlX_3 and *tert*-butyl bromide or *sec*-butyl bromide).[118] Though it is certain that these adamantane-forming reactions take place by nucleophilic 1,2 shifts, the exact pathways are not easy to unravel because of their complexity.[119] Treatment of adamantane-2-^{14}C with $AlCl_3$ results in total carbon scrambling on a statistical basis.[120]

As already indicated, the mechanism of the *Wagner–Meerwein rearrangement* is usually nucleophilic. Free radical rearrangements are also known (see Section 18.A), though virtually only with aryl migration. However, carbanion mechanisms (electrophilic)

have also been found.[94] Thus Ph_3CCH_2Cl treated with sodium gave Ph_2CHCH_2Ph along with unrearranged products.[121] This is called the *Grovenstein-Zimmerman rearrangement*. The intermediate is $Ph_3CCH_2^-$, and the phenyl moves without its electron pair. Only aryl and vinylic,[122] and not alkyl, groups migrate by the electrophilic mechanism (see the introductory section preceding Sec. 18.A) and transition states or intermediates analogous to **41** and **42** are likely.[123]

18-2 The Pinacol Rearrangement

1/*O*-Hydro,3/hydroxy-(2/→3/alkyl)-*migro*-elimination

When 1.2-diols (*vic*-diols; glycols) are treated with acids,[124] they rearrange to give aldehydes or ketones, although elimination without rearrangement can also be accomplished. This reaction is called the *pinacol rearrangement*; the reaction gets its name from a prototype compound pinacol ($Me_2COHCOHMe_2$), which is rearranged to pinacolone (Me_3C-$COCH_3$).[125] In this type of reaction, reduction can compete with rearrangement.[126] The reaction has been accomplished many times, with alkyl, aryl, hydrogen, and even ethoxycarbonyl (CO_2Et)[127] as migrating groups. In most cases, each carbon has at least one alkyl or aryl group, and the reaction is most often carried out with tri- and tetrasubstituted glycols. As mentioned earlier, glycols in which the four R groups are not identical can give rise to more than one product, depending on which group migrates (see Sec. 18.A.iii for a discussion of migratory aptitudes). A noncatalytic reaction is possible in supercritical water.[128]

Stereodifferentiation is possible in this reaction.[129] When TMSOTf was used to initiate the reaction, it was shown to be highly regioselective.[130] Mixtures are often produced, and which group preferentially migrates may depend on the reaction conditions as well as on the nature

of the substrate. Thus the action of cold, concentrated sulfuric acid on **59** produces mainly the ketone **60** (methyl migration), while treatment of **59** with acetic acid containing a trace of sulfuric acid gives mostly **61** (phenyl migration).[131] If at least one R is hydrogen, aldehydes can be produced as well as ketones. Generally, aldehyde formation is favored by the use of mild conditions (lower temperatures, weaker acids), because under more drastic conditions the aldehydes may be converted to ketones (Reaction **18-4**). The reaction has been carried out in the solid state, by treating solid substrates with HCl gas or with a solid organic acid.[132]

62

The mechanism involves a simple 1,2-shift. The ion **62** (where all four R groups are Me) has been trapped by the addition of tetrahydrothiophene.[133] A migration takes place from the tertiary position because carbocations stabilized by an oxygen atom are even more stable than tertiary alkyl cations (Sec. 5.A.ii). In addition, the new carbocation can immediately stabilize itself by losing a proton.

It is obvious that other compounds in which a positive charge can be placed on a carbon α to one bearing an OH group can also give this rearrangement. This is true for β-amino alcohols, which rearrange on treatment with nitrous acid (this is called the *semipinacol rearrangement*), for iodohydrins, for which the reagent is mercuric oxide or silver nitrate, for β-hydroxyalkyl selenides [$R^1R^2C(OH)C(SeR^5)R^3R^4$],[134] and for allylic alcohols,[135] which can rearrange on treatment with a strong acid that protonates the double bond. A related rearrangement is the Et_2Zn mediated rearrangement of bromohydrins to give ketones.[136]

A similar rearrangement is given by epoxides, when treated with acidic reagents (e.g., BF_3–etherate or $MgBr_2$–etherate), 5M $LiClO_4$ in ether,[137] $InCl_3$,[138] $Bi(OTf)_3$,[139] or sometimes by heat alone.[140] Epoxides are converted to aldehydes or ketones on treatment with certain metallic catalysts[141] including treatment with iron complexes,[142] $IrCl_3$,[143] or

with $BiOClO_4$.[144] Base-induced rearrangement is also known, but the products are usually different.[145]

The *Meinwald rearrangement* converts epoxides to carbonyl compounds.[146] Several reagents mediate this transformation, including Cu compounds.[147] A closely related reaction of vinyl epoxides gives alkenyl ketones upon treatment with Ga compounds.[148] It has been shown that epoxides are intermediates in the pinacol rearrangements of certain glycols.[149] Among the evidence for the mechanism given is that $Me_2COHCOHMe_2$, $Me_2COHC(NH_2)Me_2$, and $Me_2COHCClMe_2$ gave the reaction at different rates (as expected), but yielded the *same mixture* of two products, pinacol and pinacolone, indicating a common intermediate.[150]

A good way to prepare β-diketones consists of heating α,β-epoxy ketones at 80–140 °C in toluene with small amounts of $(Ph_3P)_4Pd$ and dppe.[151] Epoxides are converted to 1,2-diketones with Bi, DMSO, O_2 and a catalytic amounts of $Cu(OTf)_2$ at 100 °C.[152] α,β-Epoxy ketones are also converted to 1,2-diketones with a Ru catalyst[153] or an Fe catalyst.[154] Epoxides with an α-hydroxyalkyl substituent give a pinacol rearrangement product in the presence of a $ZnBr_2$[155] or $Tb(OTf)_3$[156] catalyst to give a γ-hydroxy ketone.

Oxaziridines are converted to ring-expanded lactams under photochemical conditions.[157] *N*-Tosyl aziridines with an α-hydroxyalkyl substituent give a pinacol rearrangement product in the presence of Lewis acids (e.g., SmI_2), in this case a keto-*N*-tosyl amide.[158]

β-Hydroxy ketones can be prepared by treating the silyl ethers (**63**) of α,β-epoxy alcohols with $TiCl_4$.[159]

18-3 Expansion and Contraction of Rings

Demyanov ring contraction; Demyanov ring expansion

When a positive charge is formed on an alicyclic carbon, migration of an alkyl group can take place to give ring contraction, producing a ring that is one carbon smaller than the original, as in the interconversion of the cyclobutyl cation and the cyclopropylcarbinyl cation (**64**). Note that this change involves conversion of a

64

secondary to a primary carbocation. In a similar manner, when a positive charge is placed on a carbon α to an alicyclic ring, ring expansion can take place.[160] The new carbocation, and the old one, can then give products by combination with a nucleophile (e.g., the alcohols shown above), or by elimination, so that this reaction is a special case of **18-1**. Often, both rearranged and unrearranged products are formed, so that, for example, cyclobutylamine and cyclopropylmethylamine give similar mixtures of the two alcohols shown above on treatment with nitrous acid (a small amount of 3-buten-1-ol is also produced). When the carbocation is formed by diazotization of an amine, the reaction is called the *Demyanov rearrangement*,[161] but of course similar products are formed when the carbocation is generated in other ways. The expansion reaction has been performed on rings of C_3–C_8,[162] but yields are best with the smaller rings, where relief of small-angle strain provides a driving force for the reaction. Strain is apparently much less of a factor in the cyclobutyl–cyclopropylmethyl interconversion (for a discussion of this interconversion, see Sec. 10.C.i). The influence of substituents on this rearrangement has been examined.[163] Note that a hybrid of a [1,2]-sigmatropic hydrogen shift (also See **18-29**) and a two-electron-electrocyclic ring opening has been discovered for cyclopropylcarbinyl cations that was labeled as a "hiscotropic" rearrangement."[164] The contraction reaction has been applied to four-membered rings and to rings of C_6–C_8, but contraction of a cyclopentyl cation to a cyclobutylmethyl system is generally not feasible because of the additional strain involved.

A related rearrangement involves cyclopropyl propargylic alcohols, which gives an alkylidene cyclobutanone in the presence of Ag and Au catalysts,[165] or Ru and In catalysts.[166] Cyclopropylcarbinyl rearrangements are catalyzed by ionic liquids under

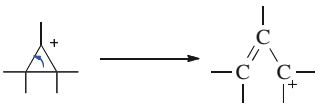
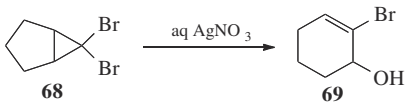
solvent-free conditions.[167] Methylenecyclopropanes rearrange to cyclobutenes in the presence of 1 atm of CO and Pt catalyst[168] or a Pd catalyst, mediated by a Cu catalyst.[169] Arylvinylidenecyclopropanes rearrange to bicyclic systems in the presence of a Lewis acid.[170]



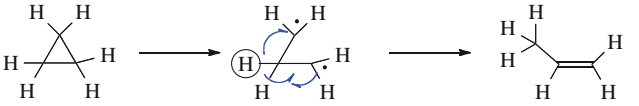
65

Ring expansions of certain hydroxyamines (e.g., **65**) are analogous to the semipinacol rearrangement (Reaction **18-2**). This reaction is called the *Tiffeneau–Demyanov ring expansion*. These have been performed on rings of C_4–C_8 and the yields are better than for the simple *Demyanov ring expansion*. A similar reaction has been used to expand rings of from five to eight members.[171] In this case, a cyclic bromohydrin of the form **66** is treated with a *Grignard reagent*, which, acting as a base, removes the OH proton to give the alkoxide **67**. When **67** is heated to reflux, ring enlargement occurs. The reaction has been done with **66** in which at least one R group is phenyl or methyl,[172] but fails when both R groups are hydrogen.[173]



66 **67**

A positive charge generated on a three-membered ring gives "contraction" to an allylic cation, as shown.[174]



As seen in Section 10.G.i, category 7, this is the reason nucleophilic substitutions are not feasible at a cyclopropyl substrate. The reaction is often used to convert cyclopropyl halides and tosylates to allylic products, especially for the purpose of ring expansion, an example being the conversion of **68** to **69**.[175] The stereochemistry of these cyclopropyl cleavages is governed by the principle of orbital symmetry conservation (for a discussion, see Reaction **18-27**, the *Möbius–Hückel method*).

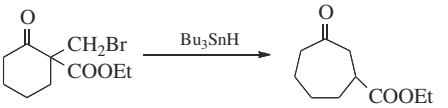
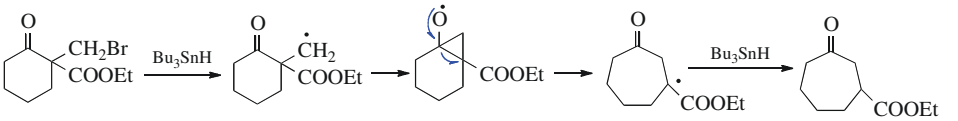
Three-membered rings can also be cleaved to unsaturated products in at least two other ways. (1) Upon pyrolysis, cyclopropanes can undergo "contraction" to propenes.[176] In the simplest case, cyclopropane gives propene when heated to 400–500 °C. The mechanism is generally regarded[177] as involving a diradical



intermediate[178] (recall that free radical 1,2-migration is possible for diradicals, Sec. 18.C). (2) The generation of a carbene or carbenoid carbon in a three-membered ring can lead to allenes, and allenes are often prepared in



this way.[179] Flash vacuum pyrolysis of 1-chlorocyclopropene thermally rearranges to chloroallene.[180] One way to generate such a species is treatment of a 1,1-dihalocyclopropane with an alkyllithium compound (Reaction **12-39**).[181] In contrast, the generation of a carbene or carbenoid at a cyclopropylmethyl carbon gives ring expansion.[182]

Some free radical ring enlargements are also known, an example being[183]:

This reaction has been used to make rings of 6, 7, 8, and 13 members. A possible mechanism is

This reaction has been extended to the expansion of rings by three or four carbons, by the use of a substrate containing $(CH_2)_nX$ ($n = 3$ or 4) instead of CH_2Br.[184] By this means, 5-, 6-, and 7-membered rings were enlarged to 18–11-membered rings. A β-keto ester (e.g., 2-carboxyethyl cyclohexanone) is converted to 3-carboxyethyl cylcoheptanone when treated with $CF_3CO_2ZnCH_2I$.[185]

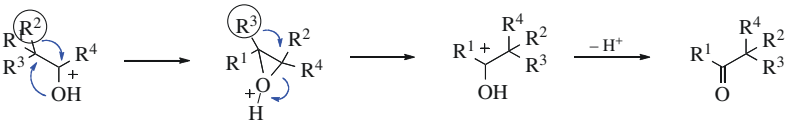
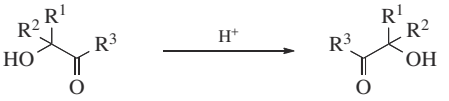
18-4 Acid-Catalyzed Rearrangements of Aldehydes and Ketones

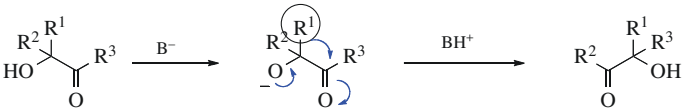


1/Alkyl,2/alkyl-interchange, and so on

Rearrangements of this type, where a group α to a carbonyl "changes places" with a group attached to the carbonyl carbon, occur when migratory aptitudes are favorable.[186] The R^2, R^3, and R^4 groups may be alkyl or hydrogen. Certain aldehydes have been converted to ketones, and ketones to other ketones (though more drastic conditions are required for the latter), but no rearrangement of a ketone to an aldehyde ($R^1 = H$) has so far been reported. There are two mechanisms,[187] each beginning with protonation of the oxygen and each involving two migrations. In one pathway, the migrations are in opposite directions[188]:



In the other pathway, the migrations are in the same direction. The actual mechanism of this pathway is not certain, but an epoxide (protonated) intermediate[189] is one possibility[190]:



If the reaction is carried out with ketone labeled in the C=O group with ^{14}C, the first pathway predicts that the product will contain all the ^{14}C in the C=O carbon, while in the second pathway the label will be in the α carbon (demonstrating migration of oxygen). The results of such experiments[191] have shown that in some cases only the C=O carbon was

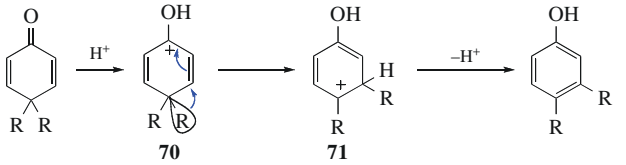
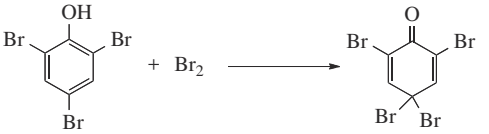
[189] Zook, H.D.; Smith, W.E.; Greene, J.L. *J. Am. Chem. Soc.* ***1957****, 79,* 4436.
[190] Some such pathway is necessary to account for the migration of oxygen that is found. It may involve a protonated epoxide, a 1,2-diol, or simply a 1,2-shift of an OH group.
[191] See Fry, A.; Oka, M. *J. Am. Chem. Soc.* ***1979****, 101,* 6353.

labeled, in other cases only the α carbon, while in still others both carbons bore the label, indicating that in these cases both pathways were in operation. With α-hydroxy aldehydes and ketones, the process may stop after only one migration (this is called the α-*ketol rearrangement*).



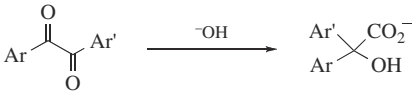
The α-ketol rearrangement can also be brought about by base catalysis, but only if the alcohol is tertiary, since if R^1 or R^2 = hydrogen, enolization of the substrate is more favored than rearrangement.



18-5 The Dienone–Phenol Rearrangement

2/*C*→5/*O*-Hydro,1/*C*→2/*C*-alkyl-bis-migration

70 **71**



Cyclohexadienone derivatives that have two alkyl groups in the 4 position undergo, on acid treatment,[192] 1,2-migration of one of these groups from **70** to give the phenol. Note that a photochemical version of this reaction has been observed.[193] The driving force in the overall reaction (the *dienone–phenol rearrangement*) is of course creation of an aromatic system.[194] Note that **70** and **71** are arenium ions (Sec. 5.A.ii), the same as those generated by attack of a phenol on an electrophile.[195] Sometimes, in the reaction of a phenol with an electrophile, a kind of reverse rearrangement (called the *phenol–dienone rearrangement)* takes place, though without an actual migration.[196] An example is

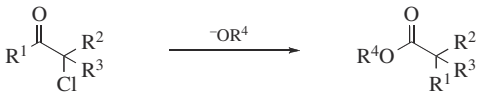
18-6 The Benzil–Benzilic Acid Rearrangement

1/*O*-Hydro,3/oxido-(1/→2/aryl)-*migro*-addition

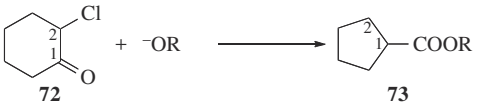
When treated with base, α-diketones rearrange to give the salts of α-hydroxy acids, a reaction known as the *benzil–benzilic acid rearrangement* (benzil is PhCOCOPh; benzilic acid is Ph_2COHCO_2H).[197] A Rh catalyzed version of this reaction has also been reported.[198] Though the reaction is usually illustrated with aryl groups, it can also be applied to aliphatic diketones[199] and to α-keto aldehydes. The use of an alkoxide instead of hydroxide gives the corresponding ester directly,[200] although alkoxide ions that are readily oxidized (e.g., OEt^- or $OCHMe_2^-$) are not useful here, since they reduce the benzil to a benzoin. The mechanism is similar to the rearrangements in Reaction **18-1**–**18-4**, but there is a difference: The migrating group does not move to a carbocation. The first step is attack of the base at the carbonyl group, the same as the first step of the tetrahedral mechanism of nucleophilic substitution (Sec. 16.A.i) and of many additions to the C=O bond (Chapter 16):



The mechanism has been intensely studied,[188] and there is much evidence for it.[201] The reaction is irreversible.

OS **I**, 89.

18-7 The Favorskii Rearrangement



2/Alkoxy-de-chloro(2/→1/alkyl)-*migro*-substitution

The reaction of α-halo ketones (chloro, bromo, or iodo) with alkoxide ions[202] to give rearranged esters is called the *Favorskii rearrangement*.[203] The use of hydroxide ions or amines as bases leads to the free carboxylic acid (salt) or amide, respectively,

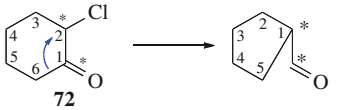
instead of the ester. Cyclic α-halo ketones give ring contraction, as in the conversion of **72** to **73**.

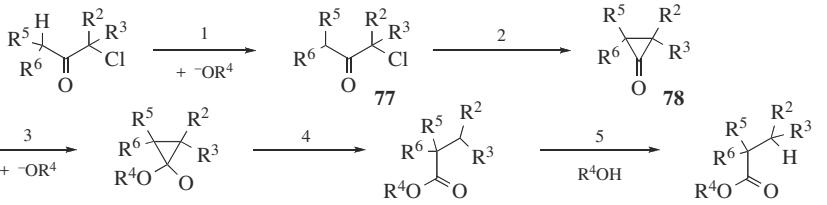


72 **73**

The reaction has also been carried out on α-hydroxy ketones[204] and on α,β-epoxy ketones, which give β-hydroxy acids.[205] The fact that an epoxide gives a reaction analogous to a halide indicates that the oxygen and halogen are leaving groups in a nucleophilic substitution step.

74 **75** **76**

Investigation of the mechanism[206] of the *Favorskii rearrangement* has led to proposals for at least five different mechanisms. However, the finding[207] that **74** and **75** *both* give **76** (this behavior is typical) shows that any mechanism where the halogen leaves and R^1 takes its place is invalid, since in such a case **74** would be expected to give **76** (with $PhCH_2$ migrating), but **75** should give PhCHMeCOOH (with CH_3 migrating). That is, in the case of **75**, it was PhCH that migrated and not methyl. Another important result was determined by radioactive labeling. Chloroketone (**72**), in which C-1 and C-2 were equally labeled with ^{14}C, was converted to **73**. The product was found to contain 50% of the label on the carbonyl carbon, 25% on C-1, and 25% on C-2.[208] Now the carbonyl carbon, which originally carried half of the radioactivity, still had this much, so the rearrangement did not directly affect *it*. However, if the C-6 carbon had migrated to C-2, the other half of the radioactivity would be only on C-1 of the product:



72

On the other hand, if the migration had gone the other way (if the C-2 carbon had migrated to C-6), then this half of the radioactivity would be found solely on C-2 of the product. The fact that C-1 and C-2 were equally labeled showed that *both migrations occurred*, with equal probability. Since C-2 and C-6 of **72** are not equivalent, this means that there must be a symmetrical intermediate.[209] The type of intermediate that best fits the circumstances is a cyclopropanone,[210] and the mechanism (for the general case) is formulated (replacing R^1

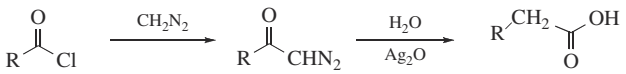
[209] A preliminary migration of the chlorine from C-2 to C-6 was ruled out by the fact that recovered **72** had the same isotopic distribution as the starting **72**.
[210] See Wasserman, H.H.; Clark, G.M.; Turley, P.C. *Top. Curr. Chem.* ***1974****, 47,* 73; Turro, N.J. *Acc. Chem. Res.* ***1969****, 2*, 25.

of our former symbolism with CHR^5R^6, since it is obvious that for this mechanism an α hydrogen is required on the non-halogenated side of the carbonyl):

The intermediate corresponding to **78**, in the case of **72**, is a symmetrical compound, and the three-membered ring can be opened with equal probability on either side of the carbonyl, accounting for the results with ^{14}C. In the general case, **78** is not symmetrical and should open on the side that gives the more stable carbanion.[211] This accounts for the fact that **74** and **75** give the same product. The intermediate in both cases is **77**, which always opens to give the carbanion stabilized by resonance. The cyclopropanone intermediate (**78**) has been isolated in the case where $R^2 = R^5 =$ *t*-Bu and $R^3 = R^6 = H$,[212] and it has also been trapped.[213] Also, cyclopropanones synthesized by other methods have been shown to give Favorskii products on treatment with NaOMe or other bases.[214]



The mechanism discussed is in accord with all the facts when the halo ketone contains an α hydrogen on the other side of the carbonyl group. However, ketones that do not have an α hydrogen also rearrange to give the same type of product in what is usually called the *quasi-Favorskii rearrangement*. The *quasi-Favorskii rearrangement* cannot take place by the cyclopropanone mechanism. The mechanism that is generally accepted (called the *semibenzilic mechanism*[215]) is a base-catalyzed pinacol rearrangement-type mechanism similar to that of **18-6**. This mechanism requires inversion at the migration terminus and this has been found.[216] It has been shown that even where there *is* an appropriately situated α hydrogen, the semibenzilic mechanism may still operate.[217]

An interesting analogue of the *Favorskii rearrangement* treats a ketone, (e.g., 4-*tert*-butylcyclohexanone), without an α-halogen with $Tl(NO_3)_3$ to give 3-*tert*-butylcyclopentane-1-carboxylic acid.[218]

In the *Arndt–Eistert synthesis*, an acyl halide is converted to a carboxylic acid with one additional carbon.[219] The first step of this process is Reaction **16-89**. The actual rearrangement occurs in the second step after treatment of the diazo ketone with water and silver oxide or with silver benzoate and triethylamine. This rearrangement is called the *Wolff rearrangement*.[220] It is the best method of increasing a carbon chain by one from a *carboxylic acid* (see Reaction **10-75** and **16-30**). If an alcohol (R′OH) is used instead of water, the ester (RCH_2CO_2R') is isolated.[221] Similarly, treatment with ammonia gives the amide. Other catalysts are sometimes used (colloidal Pt, Cu, etc.), but occasionally the diazo ketone is simply heated or photolyzed in the presence of water, an alcohol, or ammonia, with no catalyst at all using ultrasound.[222] The photolysis method[223] often gives better results than the Ag catalysis method. Of course, diazo ketones prepared in any other way also give the rearrangement.[224] The reaction is of wide scope. The R group may be alkyl or aryl and may contain many functional groups including unsaturation, but not including groups acidic enough to react with CH_2N_2 or diazo ketones (e.g., Reaction **10-5** and **10-19**). Sometimes the reaction is performed with other diazoalkanes (i.e., $R'CHN_2$) to give RCHR′COOH. The reaction has been used for ring contraction of cyclic diazo ketones[225] (e.g., **79**).[226]

79

An asymmetric variation converted ketones to esters using an azaferrocene catalyst.[227]

The mechanism is generally regarded as involving formation of a carbene.[228] It is the divalent carbon that has the open sextet and to which the migrating group brings its electron pair:

The actual product of the reaction is thus the ketene, which then reacts with water (**15-3**), an alcohol (**15-5**), or ammonia or an amine (**15-8**). Particularly stable ketenes[229]

(e.g., $Ph_2C{=}C{=}O$) have been isolated and others have been trapped in other ways (e.g., as β-lactams,[230] reaction **16-96**). The purpose of the catalyst is not well understood, though many suggestions have been made. This mechanism is strictly analogous to that of the *Curtius rearrangement* (Reaction **18-14**). Although the mechanism as shown above involves a free carbene and there is much evidence to support this,[231] it is also possible that at least in some cases the two steps are concerted and a free carbene is absent.

When the *Wolff rearrangement* is carried out photochemically, the mechanism is basically the same,[223] but another pathway can intervene. Some of the ketocarbene originally formed can undergo a carbene–carbene rearrangement, through an oxirene intermediate.[232] This was shown by ^{14}C labeling experiments, where

diazoketones labeled in the carbonyl group gave rise to ketenes that bore the label at both C=C carbons.[233] In general, the smallest degree of scrambling (and thus of the oxirene pathway) was found when R′ = H. An intermediate believed to be an oxirene has been detected by laser spectroscopy.[234] The oxirene pathway is not found in the thermal *Wolff rearrangement*. It is likely that an excited singlet state of the carbene is necessary for the oxirene pathway to intervene.[235] In the photochemical process, ketocarbene intermediates, in the triplet state, have been isolated in an Ar matrix at 10–15 K, where they have been identified by UV–visible, IR, and ESR spectra.[236] These intermediates went on to give the rearrangement via the normal pathway, with no evidence for oxirene intermediates.

The diazo ketone can exist in two conformations, called *s*-(*E*) and *s*-(*Z*). Studies have shown that *Wolff rearrangement* takes place preferentially from the *s*-(*Z*) conformation.[237]

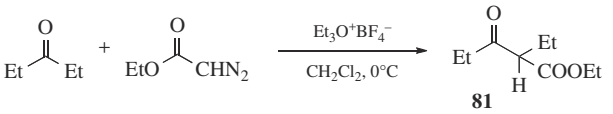
18-9 Homologation of Aldehydes and Ketones

Methylene-insertion

Aldehydes and ketones[238] can be converted to their homologues with diazomethane.[239] Several other reagents[240] are also effective, including Me_3SiI, and then silica gel.[241] With the diazomethane reaction, formation of an epoxide (**16-46**) is a side reaction. Superficially, this reaction appears to be similar to the insertion of carbenes into C—H bonds, (Reaction **12-21**, and IUPAC names it as an insertion), but the mechanism is quite different. However, it is a true rearrangement and no free carbene is involved. The first step is an addition to the C=O bond:



The betaine (**80**) can sometimes be isolated. As shown in Reaction **16-46**, intermediate **80** can also go to the epoxide. The evidence for this mechanism has been summarized in the review by Gutsche.[239] Note that this mechanism is essentially the same as in the apparent "insertions" of oxygen (Reaction **18-19**) and nitrogen (Reaction **18-16**) into ketones.

1,3-Diketones are converted to 1,4-diketones upon treatment with $CF_3CO_2ZnCH_2I$.[242] In a related reaction, alkenes insert into aldehydes in the presence of a Rh catalyst to give the corresponding ketone.[243]

Aldehydes give fairly good yields of methyl ketones; that is, hydrogen migrates in preference to alkyl. The most abundant side product is not the homologous aldehyde, but the epoxide. However, the yield of aldehyde at the expense of methyl ketone can be increased by the addition of methanol. If the aldehyde contains electron-withdrawing groups, the yield of epoxides is increased and the ketone is formed in smaller amounts, if at all. Ketones give poorer yields of homologous ketones. Epoxides are usually the predominant product here, especially when one or both R groups contain an electron-withdrawing group. The yield of ketones also decreases with increasing length of the chain. The use of a Lewis acid increases the yield of ketone.[244] Cyclic ketones,[245] three membered[246] and larger, behave particularly well and give good yields of ketones with the ring expanded by one.[247] Aliphatic diazo compounds ($RCHN_2$ and R_2CN_2) are sometimes used instead of

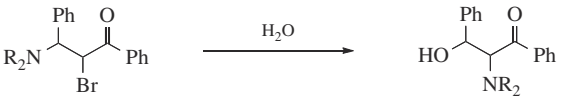
diazomethane, with the expected results.[248] Ethyl diazoacetate can be used analogously, in the presence of a Lewis acid or of triethyloxonium fluoroborate,[249] to give a β-keto ester, (e.g., **81**).

81

When unsymmetrical ketones were used in this reaction (with BF_3 as catalyst), the less highly substituted carbon preferentially migrated.[250] The reaction can be made regioselective by applying this method to the α-halo ketone, in which case only the other carbon migrates.[251] The ethyl diazoacetate procedure has also been applied to the acetals or ketals of α,β-unsaturated aldehydes and ketones.[252]

Bicyclic ketones can be expanded to form monocyclic ketones in the presence of certain reagents. Treatment of a bicyclo[4.1.0]hexan-4-one derivative with SmI_2 led to a cyclohexanone.[253] The SmI_2 also converts α-halomethyl cyclic ketones to the next larger ring ketone[254] and cyclic ketones to the next larger ring ketone in the presence of CH_2I_2.[255]



Another homologation reaction converts an aldehyde to its tosyl hydrazone, and subsequent reaction with an aldehyde and NaOEt/EtOH give a ketone.[256] The reaction of an aldehyde with vinyl acetate and $Ba(OH)_2$ gives the homologated conjugated aldehyde.[257]

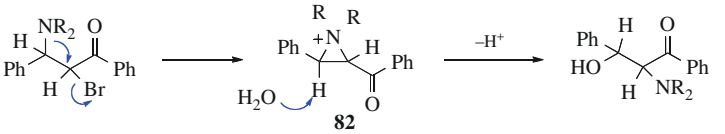
B. Carbon-to-Carbon Migrations of Other Groups

18-10 Migrations of Halogen, Hydroxyl, Amino, and so on



Hydroxy-de-bromo-*cine*-substitution, and so on

When a nucleophilic substitution is carried out on a substrate that has a neighboring group (Sec. 10.C) on the adjacent carbon, a cyclic intermediate can be generated that is opened on the opposite side, resulting in migration of the neighboring group. In the example shown above (NR_2 = morpholino),[258] the reaction took place via an aziridinium salt (**82**) to give an α-amino-β-hydroxy ketone. Sulfonate esters and halides can also

migrate in this reaction.[259]

α-Halo and α-acyloxy epoxides undergo ready rearrangement to α-halo and α-acyloxy ketones, respectively.[260] These substrates are prone to rearrange, and often do so upon standing without a catalyst, although an acid catalyst is necessary in some cases. The reaction is essentially the same as the rearrangement of epoxides shown in **18-2**, except that halogen or acyloxy is the migrating group (as shown above; however, it is also possible for one of the R groups (alkyl, aryl, or hydrogen) to migrate instead, and mixtures are sometimes obtained). In a related reaction, α-bromoaziridines undergo rearrangement to the isomerized α-bromoaziridine in the presence of $MgBr_2$.[261]

In the presence of a Cu catalyst, alkenyl epoxides (vinyl oxiranes) rearrange to a 2,5-dihydrofuran.[262] Alkenyl thiiranes are similarly converted to 2,5-dihydrothiophenes with a Cu catalyst.[263]

Allylic alcohols migrate to give a new allylic alcohol in the presence of a Re catalyst. An example is the conversion of **83** to **84**.[264] Variations using Rh[265] or Ir[266] catalysts are known, and methanesulfonic acid catalyzes the isomerization.[267] In the presence of a Ru catalyst, an allylic alcohol was isomerized to an aliphatic ketone.[268] There is a similar Au catalyzed isomerization of allylic acetates.[269]

83 **84**

The *Meyer–Schuster Rearrangement* is an acid-catalyzed rearrangement of a propargyl alcohol to a conjugated carbonyl compound.[270] Rearrangement was also catalyzed by a cationic Rh–bisphosphane complex.[271] An Au catalyzed rearrangement of ethoxyalkynyl carbinols gave α,β-unsaturated esters.[272] The base-induced isomerization of a propargylic

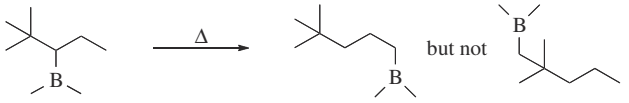
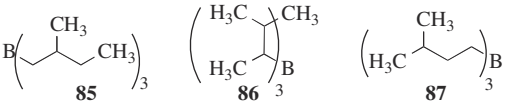
alcohol gave a conjugated ketone,[273] and a combination of Mo—Au led to rapid 1,3-rearrangement of propargyl alcohols.[274] An Au—Ag catalyzed reaction with propargyl esters gave a 2-O-pivaloyl conjugated aldehyde.[275] A similar reaction with a Pt catalyst converted a 1-ethoxy propargylic ester to a 2-carboethoxy conjugated ketone.[276] An Au catalyzed isomerization of allenyl carbinol esters is also known.[277]

18-11 Migration of Boron



Hydro,dialkylboro-interchange, and so on



Boranes are prepared by the reaction of BH_3 (B_2H_6) or an alkylborane with an alkene (**15-16**). When a nonterminal borane is heated at temperatures ranging from 100 to 200 °C, the boron moves toward the end of the chain.[278] The reaction is catalyzed by small amounts of borane or other species containing B—H bonds. The boron can move past a branch, for example,

but not past a double branch, for example,

The reaction is an equilibrium: **85**, **86**, and **87** each gave a mixture containing ~40% **85**, 1% **86**, and 59% **87**. The migration can go quite a long distance, including a migration of 11 positions.[279] If the boron is on a cycloalkyl ring, it can move around the ring; if any alkyl chain is also on the ring, the boron may move from the ring to the chain, ending up at the end of the chain.[280] The reaction is useful for the migration of double bonds in a controlled way (see **12-2**). The mechanism may involve a π complex, at least partially.[281]

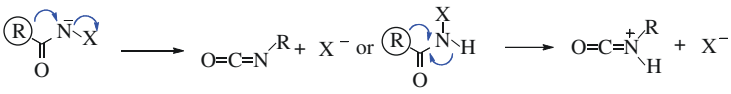
18-12 The Neber Rearrangement

Neber oxime tosylate-amino ketone rearrangement

α-Amino ketones can be prepared by treatment of ketoxime tosylates with a base (e.g., ethoxide or pyridine).[282] This reaction is called the *Neber rearrangement*. The R group is usually aryl, although the reaction has been carried out with R = alkyl or hydrogen. The R′ group may be alkyl or aryl, but not hydrogen. The *Beckmann rearrangement* (Reaction **18-17**) and the abnormal *Beckmann reaction* (elimination to the nitrile, Reaction **17-30**) may be side reactions, although these generally occur in acid media. A similar rearrangement is given by *N,N*-dichloroamines of the type $RCH_2CH(NCl_2)R'$, where the product is also $RCH(NH_2)COR'$.[283] The mechanism of the Neber rearrangement involves an azirine intermediate (**88**).[284] The best evidence for this mechanism is that the azirine intermediate has been isolated.[285,] In contrast to the *Beckmann rearrangement*, this one is sterically indiscriminate:[286] Both a syn and an anti ketoxime give the same product. The mechanism, as shown above, consists of three steps. However, it is possible that the first two steps are concerted, and it is also possible that what is shown as the second step is actually two steps: loss of OTs to give a nitrene, and formation of the azirine. In the case of the dichloroamines, HCl is first lost to give $RCH_2C(=NCl)R'$, which then behaves analogously.[287] *N*-Chloroimines prepared in other ways also give the reaction.[288] Indoles have been prepared via a *Neber rearrangement*.[289]



OS **V**, 909; **VII**, 149.

C. Carbon-to-Nitrogen Migrations of R and Ar

The reactions in this group are nucleophilic migrations from a carbon to a nitrogen atom. In each case, the nitrogen atom either has six electrons in its outer shell (and thus invites the migration of a group carrying an electron pair) or else loses a nucleofuge concurrently with the migration (Sec. 18.A.i). Reactions **18-13**–**18-16** are used to prepare amines from acid derivatives. Reactions **18-16** and **18-17** are used to prepare amines from ketones. The mechanisms of Reaction **18-13**–**18-16** (with carboxylic acids) are very similar and follow

one of two patterns:

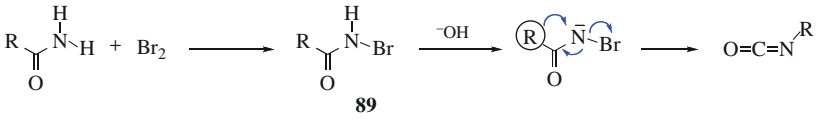
Some of the evidence[290] is (1) configuration is retained in R (Sec. 18.A.ii); (2) the kinetics are first order; (3) intramolecular rearrangement is shown by labeling; and (4) no rearrangement occurs *within* the migrating group, for example, a neopentyl group on the carbon of the starting material is still a neopentyl group on the nitrogen of the product.

In many cases, it is not certain whether the nucleofuge X is lost first, creating an intermediate nitrene[291] or nitrenium ion, or whether migration and loss of the nucleofuge are simultaneous, as shown above.[292] It is likely that both possibilities can exist, depending on the substrate and reaction conditions.

18-13 The Hofmann Rearrangement

Bishydrogen-(2/→1/*N*-alkyl)-*migro*-detachment (formation of isocyanate)

In the *Hofmann rearrangement*, an unsubstituted amide is treated with sodium hypobromite (or sodium hydroxide and bromine, which is essentially the same thing) to give an isocyanate, but this compound is seldom isolated[293] since it is usually hydrolyzed under the reaction conditions. The final isolated product is a primary amine that has one carbon fewer than the starting amide.[294] The R group may be alkyl or aryl, but if it is an alkyl group of more than about six or seven carbons, low yields are obtained unless Br_2 and NaOMe are used instead of Br_2 and NaOH.[295] Another modification uses NBS/NaOMe.[296] Under these conditions, the product of addition to the isocyanate is the carbamate (RNHCOOMe, Reaction **16-8**), which is easily isolated or can be hydrolyzed to the amine.[297] A mixture of NBS and DBU (see Reaction **17-13**) in methanol gives the carbamate,[298] as does electrolysis in methanol.[299]



Side reactions when NaOH is the base are formation of ureas (RNHCONHR) and acylureas (RCONHCONHR) by addition, respectively, of RNH_2 and $RCONH_2$ to RNCO (**16-20**). If acylureas are desired, they can be made the main products by using only one-half of the usual quantities of Br_2 and NaOH. Another side product, but only from primary R, is the nitrile derived from oxidation of RNH_2 (Reaction **19-5**).

Imides react to give amino acids, (e.g., phthalimide gives *o*-aminobenzoic acid). α-Hydroxy and α-halo amides give aldehydes and ketones by way of the unstable

α-hydroxy- or α-haloamines. However, a side product with an α-halo amide is a *gem*-dihalide. Ureas analogously give hydrazines.

The mechanism follows the pattern outlined in the discussion preceding Reaction **18-13**.

The first step is an example of Reaction **12-52** and intermediate *N*-halo amides (**89**) have been isolated. Compound **89** is acidic because of the presence of two electron-withdrawing groups (acyl and halo) on the nitrogen, and in the second step, **89** loses a proton to the base. It is possible that the third step is actually two steps: loss of bromide to form a nitrene, followed by the actual migration, but most of the available evidence favors the concerted reaction.[300] A similar reaction can be effected by the treatment of amides with lead tetraacetate.[301] Among other reagents that convert $RCONH_2$ to RNH_2 (R = alkyl, but not aryl) are phenyliodosyl bis(trifluoroacetate) [$PhI(OCOCF_3)_2$][302] and hydroxy(tosyloxy) iodobenzene [PhI(OH)OTs].[303]

A variation of the *Hofmann rearrangement* treated a β-hydroxy primary amide with $PhI(O_2CCF_3)_3$ in aq acetonitrile, giving an isocyanate via –CON-I, which reacts with the hydroxyl group intramolecularly to give a cyclic carbamate.[304] Note that carbamates are converted to isocyanates by heating with Montmorillonite K-10.[305]

OS **II**, 19, 44, 462; **IV**, 45; **VIII**, 26, 132.

18-14 The Curtius Rearrangement

Dinitrogen-(2/→1/*N*-alkyl)-*migro*-detachment

$$RCON_3 \xrightarrow{\Delta} R{-}N{=}C{=}O$$

The *Curtius rearrangement* involves heating acyl azides to yield isocyanates.[306] The reaction gives good yields of isocyanates, since no water is present to hydrolyze them to the amine. Of course, they can be subsequently hydrolyzed, and indeed the reaction *can* be carried out in water or alcohol, in which case the products are amines, carbamates, or acylureas, as in **18-13**.[307] This is a very general reaction and can be applied to almost any carboxylic acid: aliphatic, aromatic, alicyclic, heterocyclic, unsaturated, and containing many functional groups. Acyl azides can be prepared as in Reaction **10-43** or by treatment

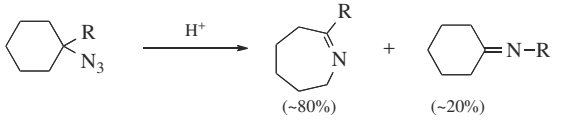
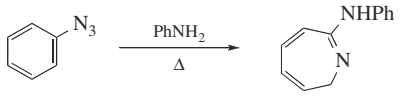
of acylhydrazines (hydrazides) with nitrous acid (analogous to Reaction **12-49**). The Curtius rearrangement is catalyzed by Lewis acids or protic acids, but these are usually not necessary for good results.



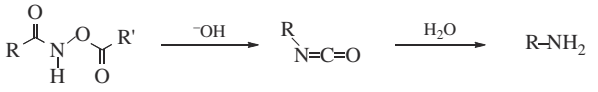
The mechanism is similar to that in Reaction **18-13** to give an isocyanate. Also note the exact analogy between this Reaction and **18-8**. However, in this case, there is no evidence for a free nitrene and it is probable that the conversion is concerted.[308]



Alkyl azides can be similarly pyrolyzed to give imines, in an analogous reaction[309]:

$$R_3CN_3 \xrightarrow{\Delta} R_2C{=}NR$$

The R groups may be alkyl, aryl, or hydrogen, although if hydrogen migrates, the product is the unstable $R_2C{=}NH$. The mechanism is essentially the same as that of the *Curtius rearrangement*. However, in pyrolysis of tertiary alkyl azides, there is evidence that free alkyl nitrenes are intermediates.[310] The reaction can also be carried out with acid catalysis, in which case lower temperatures can be used, although the acid may hydrolyze the imine (**16-2**). Cycloalkyl azides give ring expansion as shown.[311]



Aryl azides also give ring expansion on heating, for example,[312]

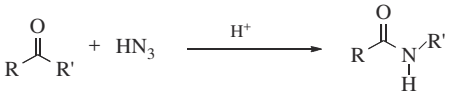
The *O*-acyl derivatives of hydroxamic acids[313] give isocyanates when treated with bases or sometimes even just on heating, in a reaction known as the *Lossen rearrangement*.[314] The mechanism is similar to that of Reaction **18-13** and **18-14**:

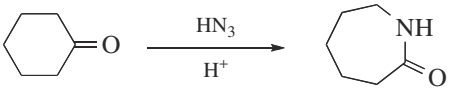
In a similar reaction, aromatic acyl halides are converted to amines in one laboratory step by treatment with hydroxylamine-*O*-sulfonic acid.[315]



A chiral *Lossen rearrangement* is known.[316]

18-16 The Schmidt Reaction

There are actually three reactions called by the name *Schmidt reaction*, involving the addition of hydrazoic acid to carboxylic acids, aldehydes and ketones, and alcohols and alkenes.[317] The most common is the reaction with carboxylic acids, illustrated above.[318] Sulfuric acid is a common catalyst, but Lewis acids have also been used. Good results are obtained for aliphatic R, especially for long chains. When R is aryl, the yields are variable, being best for sterically hindered compounds like mesitoic acid. This method has the advantage over Reaction **18-13** and **18-14** in that there is just one laboratory step from the acid to the amine, but conditions are more drastic.[319] Under the acid conditions employed, the isocyanate is virtually never isolated.



The reaction between a ketone and hydrazoic acid is a method for "insertion" of NH between the carbonyl group and one R group, converting a ketone into an amide.[320]

Either or both of the R groups may be aryl. In general, dialkyl ketones and cyclic ketones react more rapidly than alkyl aryl ketones, and these more rapidly than diaryl ketones. The latter require sulfuric acid and do not react in concentrated HCl, which is strong enough for

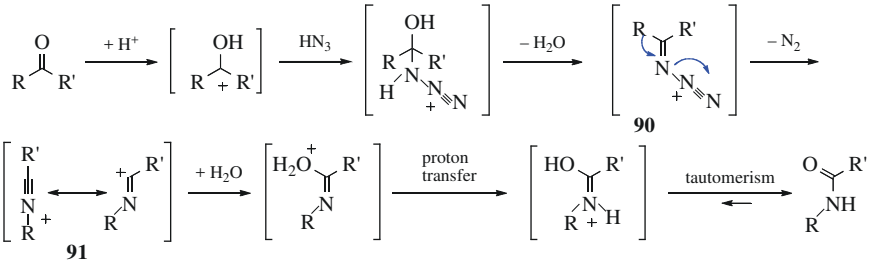
dialkyl ketones. Dialkyl and cyclic ketones react sufficiently faster than diaryl or aryl alkyl ketones or carboxylic acids or alcohols so that these functions may be present in the same molecule without interference. Cyclic ketones give lactams[321]: With alkyl aryl ketones, it is the aryl group that generally migrates to the nitrogen, except when the alkyl group is bulky.[322]

The reaction has been applied to a few aldehydes, but rarely. With aldehydes the product is usually the nitrile (Reaction **16-16**). Even with ketones, conversion to the nitrile is often a side reaction, especially with the type of ketone that gives **17-30**. A useful variation of the Schmidt reaction treats a cyclic ketone with an alkyl azide (RN_3)[323] in the presence of $TiCl_4$, generating a lactam.[324] An intramolecular *Schmidt reaction* gives bicyclic amines.[325] Another variation treats a silyl enol ether of a cyclic ketone with $TMSN_3$ and photolyzes the product with UV light to give a lactam.[326] An α–azido cyclic ketone rearrangement to lactams under radical conditions (Bu_3SnH/AIBN).[327]

Alcohols and alkenes react with HN_3 to give alkyl azides,[328] which in the course of reaction rearrange in the same way as discussed in Reaction **18-14**.[309] The *Mitsunobu Reaction* (**10-17**) can be used to convert alcohols to alkyl azides, and an alternative reagent for azides [$(PhO)_2PON_3$], for use in the *Mitsunobu* is now available.[329] In the presence of an Au catalyst, an acetylenic azide was converted to a pyrrole derivative.[330] An intramolecular *Schmidt reaction* gives bicyclic lactams in the presence of $MeAlCl_2$.[331]



There is evidence that the mechanism with carboxylic acids[320] is similar to that of Reaction **18-14**, except that it is the protonated azide that undergoes the rearrangement[332]:

The first step is the same as that of the $A_{AC}1$ mechanism (Reaction **16-59**, which explains why good results are obtained with hindered substrates. The mechanism with ketones

18-17 The Beckmann Rearrangement

Beckmann oxime–amide rearrangement

When oximes are treated with PCl_5 or a number of other reagents, they rearrange to substituted amides in a reaction called the *Beckmann rearrangement*.[335] Reagents used include concentrated H_2SO_4 acid, formic acid, liquid SO_2, silica gel,[336] $RuCl_3$,[337] $Y(OTf)_3$,[338] I_2,[339] $HgCl_2$,[340] triphosphazene,[341] bromodimethylsulfonium bromide–$ZnCl_2$,[342] neat with $FeCl_3$,[343] cyanuric acid,[344] and polyphosphoric acid.[345] Simply heating the oxime of benzophenone neat leads to *N*-phenyl benzamide.[346] The reaction has been

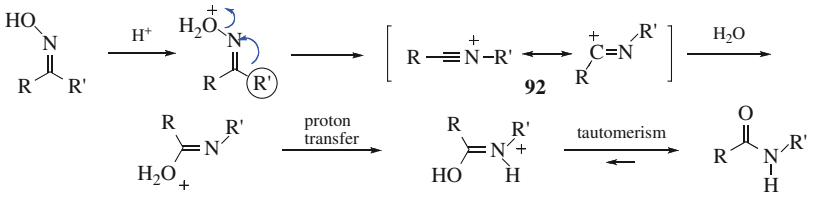
done in supercritical water[347] and in ionic liquids.[348] A polymer-bound Beckman rearrangement has been reported.[349] Microwave assisted *Beckmann rearrangements* are known.[350] Note that the reaction of an imine with $BF_3{\cdot}OEt_2$ and *m*-chloroperoxybenzoic acid leads to a formamide.[351]

The oximes of cyclic ketones give ring enlargement and form the lactam,[352] as in the formation of caprolactam (see Reaction **18-16**) from the oxime of cyclohexanone. Solvent-free reactions are known.[353] Cyclic ketones can be converted directly to lactams in one laboratory step by treatment with NH_2OSO_2OH and formic acid (Reaction **16-14** takes place first, then the *Beckmann rearrangement*).[354]



Of the groups attached to the carbon of the C=N unit, the one that migrates in the *Beckman rearrangement* is generally the one anti to the hydroxyl, and this is often used as a method of determining the configuration of the oxime. However, it is not unequivocal. It is known that with some oximes the syn group migrates and that with others, especially where R and R′ are both alkyl, mixtures of the two possible amides are obtained. However, this behavior does not necessarily mean that the syn group actually undergoes migration. In most cases, the oxime undergoes isomerization under the reaction conditions *before* migration takes place.[355] The scope of the reaction is quite broad and R and R′ may be alkyl, aryl, or hydrogen. However, hydrogen very seldom migrates, so the reaction is not generally a means of converting aldoximes to unsubstituted amides ($RCONH_2$). This latter conversion can be accomplished, however, by treatment of the aldoxime with nickel acetate under neutral conditions[356] or by heating the aldoxime for 60 h at 100 °C after it has been adsorbed onto silica gel.[357] As in the case of the *Schmidt rearrangement* (Reaction **18-16**), when the oxime is derived from an alkyl aryl ketone, it is generally the aryl group that preferentially migrates.[358]

Not only do oximes undergo the *Beckmann rearrangement*, but so also do esters of oximes with many acids, organic and inorganic. A side reaction with many substrates is the formation of nitriles (the "abnormal" *Beckmann rearrangement*, Reaction **17-30**). The *O*-carbonates of imines (e.g., $Ph_2C{=}N{-}OCO_2Et$) react with $BF_3{\cdot}OEt_2$ to give the corresponding amide in this case *N*-phenyl benzamide.[359]

In the first step of the mechanism, the OH group is converted by the reagent to a better leaving group, for example, proton acids convert it to OH_2^+. After that, the mechanism[360] follows a course analogous to that for the *Schmidt reaction* of ketones (**18-16**) from the

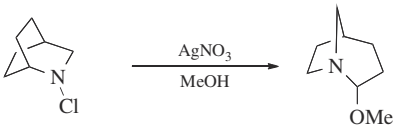
formation of nitrilium ion (**92**) on[361]: Alternative modes of reaction are possible. For example, when PCl_5 is used to induce the reaction, a N-O-PCl_4 species is formed, which generates **92**. Intermediates of the form **92** have been detected by NMR and UV spectroscopy.[362] The rearrangement has also been found to take place by a different mechanism, involving formation of a nitrile by fragmentation, and then addition by a *Ritter Reaction* (**16-91**).[363] *Beckmann rearrangements* have also been carried out photochemically.[364] A computational study compared converted versus stepwise mechanisms for the *Beckmann rearrangement*, and found that proton relay between the substrate and the solvent molecules controls the reaction, and migration and N—O bond scission occur simultaneously.[365]



If the rearrangement of oxime sulfonates is induced by organoaluminum reagents,[366] the nitrilium ion intermediate (**92**) is captured by the nucleophile originally attached to the Al. By this means an oxime can be converted to an imine, an imino thioether (R—N=C—SR), or an imino nitrile (R—N=C—CN).[367] In the last case, the nucleophile comes from added trimethylsilyl cyanide. In the presence of LiI, 2-benzyloxypyridine is converted to *N*-benzyl-2-pyridone.[368]

In a related reaction, treatment of spirocyclic oxaziridines with MnCl(tpp) (tpp = triphenylphosphine, ligand)[369] or photolysis[370] leads to a lactam.

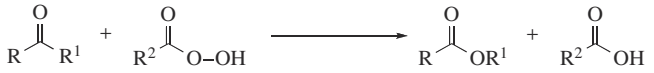
N-chloro-2-azabicyclo[2.2.2]octane, above), undergo rearrangement when solvolyzed in the presence of silver nitrate.[371] This reaction is similar to the *Wagner–Meerwein rearrangement* (**18-1**) and is initiated by the silver-catalyzed departure of the chloride ion.[372] Similar reactions have been used for ring expansions and contractions, analogous to those discussed for Reaction **18-3**.[373] An example is the conversion of 1-(*N*-chloroamino)cyclopropanols to β-lactams.[374] Methyl prolinate was converted to the 2-piperidone upon treatment with SmI_2 and pivalic acid–THF.[375]

The name *Stieglitz rearrangement* is generally applied to the rearrangements of trityl *N*-haloamines and



hydroxylamines. These reactions are similar to the rearrangements of alkyl azides (**18-14**), and the name *Stieglitz rearrangement* is also given to the rearrangement of trityl azides. Another similar reaction is the rearrangement undergone by tritylamines when treated with lead tetraacetate ($Ar_3CNH_2 \rightarrow Ar_2C{=}NAr$.[376]

D. Carbon-to-Oxygen Migrations of R and Ar

18-19 The Baeyer–Villiger Rearrangement[377]

Oxy-insertion

The treatment of ketones with peroxyacids (e.g., peroxybenzoic or peroxyacetic acid or with other peroxy compounds in the presence of acid catalysts, gives carboxylic esters by migration of an alkyl group oxygen[378] and the carboxylic acid parent of the peroxyacid as a byproduct. In other words, there is a C → O rearrangement, and the reaction is called the *Baeyer–Villiger rearrangement*.[379] A particularly good reagent is peroxytrifluoroacetic

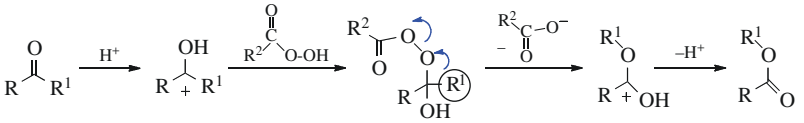
acid. Reactions with this reagent are rapid and clean, giving high yields of product, although it is often necessary to add a buffer (e.g., Na_2HPO_4), to prevent transesterification of the product with trifluoroacetic acid that is also formed during the reaction. The reaction is often applied to cyclic ketones to give lactones.[380] Hydrogen peroxide has been used to convert cyclic ketones to lactones using a catalytic amount of $MeReO_3$[381] or a diselenide catalyst.[382] Heterogeneous catalysts are used for the *Baeyer–Villiger reaction*.[383] Transition metal catalysts have been used with peroxyacids to facilitate the oxidation.[384] Polymer-supported peroxy acids have been used,[385] and solvent-free *Bayer–Villiger reactions* are known.[386] Potassium peroxomonosulfate supported on acidic silica gel has been used.[387]



Enantioselective synthesis[388] of chiral lactones from achiral ketones has been achieved by the use of enzymes[389] and other asymmetric reactions are known.[390] Chiral Pd complexes give chiral lactones from cyclic ketones with high enantioselectively.[391] Other chiral catalysts include those based on Al.[392] *Baeyer–Villiger oxidation* of chiral substrates with *m*-chloroperoxybenzoic acid (mcpba) also leads to chiral lactones.[393]

For acyclic compounds, R′ must usually be secondary, tertiary, or vinylic, although primary R′ has been rearranged with peroxytrifluoroacetic acid,[394] with $I_2—H_2O_2$,[395] $BF_3—H_2O_2$,[396] and with $K_2S_2O_8—H_2SO_4$.[397] For unsymmetrical ketones, the approximate order of migration is tertiary alkyl > secondary alkyl, aryl > primary alkyl > methyl. Since the methyl group has a low migrating ability, the reaction provides a means of cleaving a methyl ketone (R′COMe) to produce an alcohol or phenol (R′OH, by hydrolysis of the ester R′OCOMe). The migrating ability of aryl groups is increased by electron-donating and decreased by electron-withdrawing substituents.[398] There is a preference of *anti*- over *gauche* migration.[399]

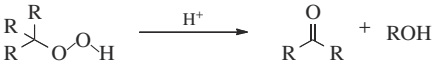
Enolizable β-diketones do not react. α-Diketones can be converted to anhydrides.[400] With aldehydes, migration of hydrogen gives the carboxylic acid, and this is a way of accomplishing Reaction **19-23**. Migration of the other group would give formates, but this seldom happens, though aryl aldehydes have been converted to formates with H_2O_2 and a selenium compound[401] (see also, the *Dakin Reaction* in **19-11**).



The mechanism[402] is similar to those of the analogous reactions with hydrazoic acid (**18-16** with ketones) and diazomethane (**18-8**):

One important piece of evidence for this mechanism was that benzophenone–^{18}O gave ester entirely labeled in the carbonyl oxygen, with none in the alkoxyl oxygen.[403] Carbon-14 isotope-effect studies on acetophenones have shown that migration of aryl groups takes place in the rate-determining step,[404] demonstrating that migration of Ar is concerted with departure of $OCOR^2$.[405] It is hardly likely that migration would be the slow step if the leaving group departed first to give an ion with a positive charge on an oxygen atom, which would be a highly unstable species.

18-20 Rearrangement of Hydroperoxides

C-Alkyl-*O*-hydroxy-elimination

Hydroperoxides (R = alkyl, aryl, or hydrogen) can be cleaved by proton or Lewis acids in a reaction whose principal step is a rearrangement.[406] The reaction has also been applied to peroxy esters ($R_3COOCOR'$), but less often. When aryl and alkyl groups are both present, migration of aryl dominates. It is not necessary actually to prepare and isolate hydroperoxides. The reaction takes place when the alcohols are treated with H_2O_2 and acids. Migration of an alkyl group of a primary hydroperoxide provides a means for converting an alcohol to its next lower homolo ($RCH_2OOH \rightarrow CH_2{=}O + ROH$).

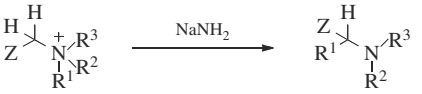
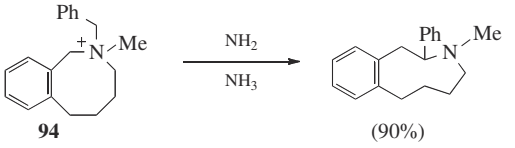
The mechanism is as follows[407]:



The last step is hydrolysis of the unstable hemiacetal. Alkoxycarbocation intermediates (**93**, R = alkyl) have been isolated in superacid solution[408] at low temperatures, and their structures proved by NMr.[409] The protonated hydroperoxides could not be observed in these solutions, evidently reacting immediately on formation.

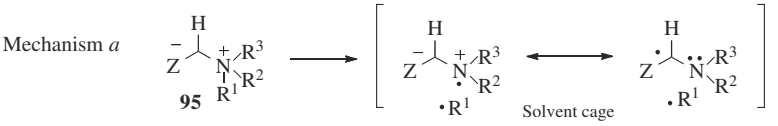
OS **V**, 818.



E. Nitrogen-to-Carbon, Oxygen-to-Carbon, and Sulfur-to-Carbon Migration

18-21 The Stevens Rearrangement

Hydron-(2/*N*→1/alkyl)-*migro*-detachment



In the *Stevens rearrangement*,[410] a quaternary ammonium salt containing an electron-withdrawing group Z on one of the carbons attached to the nitrogen is treated with a strong base (e.g., NaOR or $NaNH_2$) to give a rearranged tertiary amine. The Z group may be RCO, ROOC, or phenyl.[411] The most common migrating groups are allylic, benzylic, benzhydryl, 3-phenylpropargyl, and phenacyl, though even methyl migrates to a sufficiently negative center. Migration of aryl is rare, but has been reported.[412] When an allylic group migrates, it may or may not involve an allylic rearrangement within the migrating group (see Reaction **18-35**), depending on the substrate and reaction conditions. The reaction has been used for ring enlargement,[413] illustrated by the rearrangement of **94**.

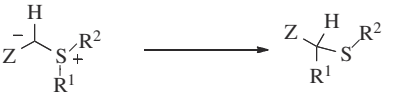
The mechanism has been the subject of much study.[414] The rearrangement is intramolecular, as shown by cross-over experiments, by ^{14}C labeling,[415] and by the fact that retention of configuration is found at R^1.[416] The first step is loss of the acidic proton to give the ylid (**95**), which has been isolated.[417] The finding[418] that CIDNP is observed[419] in many instances shows that in these cases the product is formed directly from a free-radical precursor. The following radical pair mechanism was proposed[420]:

The radicals do not drift apart because the solvent cage holds them together. According to this mechanism, the radicals must recombine rapidly in order to account for the fact that R^1 does not racemize. Other evidence in favor of mechanism *a* is that in some cases small amounts of coupling products (R^1–R^1) have been isolated,[421] which would be expected if some $\bullet R^1$ leaked from the solvent cage. However, not all the evidence is easily compatible with mechanism *a*.[422] It is possible that another mechanism (*b*), similar to mechanism *a*, but



involving ion pairs in a solvent cage instead of radical pairs, operates in some cases. A third possible mechanism would be a concerted 1,2-shift,[423] but the orbital symmetry principle requires that this take place with inversion at R^1.[424] (see Reaction **18-30** and [1,5]-migration). *Since the actual migration takes place with retention, it cannot, according to this argument, proceed by a concerted mechanism.* However, in the case where the migrating group is allylic, a concerted mechanism can also operate (Reaction **18-35**). An interesting finding compatible with all three mechanisms is that optically active allylbenzylmethylphenylammonium iodide (asymmetric nitrogen, see Sec. 4.C, category 3) gave an optically active product[425]:

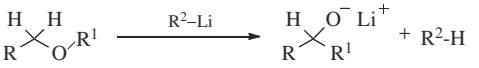
The *Sommelet–Hauser rearrangement* competes when Z is an aryl group (see Reaction **13-31**). *Hofmann elimination* competes when one of the R groups contains a β hydrogen atom (Reaction **17-7** and **17-8**).

Sulfur ylids containing a Z group give an analogous rearrangement (see the reaction), sometimes referred to as a *Stevens rearrangement*.[426] In this case too, there is much evidence (including CIDNP) that a radical-pair cage mechanism is operating,[427] except that when the migrating group is allylic, the mechanism may be different (see Reaction **18-35**).



Another reaction with a similar mechanism[428] is the *Meisenheimer rearrangement*,[429] in which certain tertiary amine oxides rearrange on heating to give substituted hydroxylamines (see reaction).[430] The migrating group R^1 is almost always allylic or benzilic.[431] Both R^2 and R^3 may be alkyl or aryl, but if one of the R groups contains a β hydrogen, *Cope elimination* (Reaction **17-9**) often competes. In a related reaction, when 2-methylpyridine *N*-oxides are treated with trifluoroacetic anhydride, the *Boekelheide reaction* occurs to give 2-hydroxymethylpyridines.[432]

Certain tertiary benzylic amines, when treated with BuLi, undergo a rearrangement analogous to the *Wittig rearrangement* (Reaction **18-22**, e.g., $PhCH_2NPh_2 \rightarrow Ph_2CHNHPh$).[433] Only aryl groups migrate in this reaction.

Isocyanides, when heated in the gas phase or in nonpolar solvents, undergo a 1,2-intramolecular rearrangement to nitriles (RNC → RCN).[434] In polar solvents, the mechanism is different.[435]

The rearrangement of ethers upon treatment with alkyllithium reagents is called the *Wittig rearrangement* (not to be confused with the *Wittig Reaction*, **16-44**) and is similar to **18-21**.[411] However, a stronger base is required (e.g., phenyllithium or sodium amide). The R and R′ groups may be alkyl,[437] aryl, or vinylic.[438] Also, one of the hydrogen atoms may be replaced by an alkyl or aryl group, in which case the product is the salt of a tertiary alcohol. Migratory aptitudes here are allylic, benzylic > ethyl > methyl > phenyl.[439] The stereospecificity of the *1,2-Wittig rearrangement* has been discussed.[440] The following radical-pair mechanism[441] (similar to mechanism *a* of Reaction **18-21**) is likely, after removal of the proton by the base. One of the

the radical pair is a ketyl. Evidence for this mechanism includes (1) the rearrangement is largely intramolecular; (2) migratory aptitudes are in the order of free-radical stabilities, not of carbanion stabilities[442] (which rules out an ion-pair mechanism similar to mechanism *b* of Reaction **18-21**); (3) aldehydes are obtained as side products[443]; (4) partial racemization of R′ has been observed[444] (the remainder of the product retained its configuration); (5) cross-over products have been detected[445]; and (6) when ketyl radicals and R• radicals from different precursors were brought together, similar products resulted.[446] However, there is evidence that at least in some cases the radical-pair mechanism accounts for only a portion of the product, and some kind of concerted mechanism can also take place.[447] Most of the above investigations were carried out with systems where R′ is alkyl, but a radical-pair mechanism has also been suggested for the case where R′ is aryl.[448] When R′ is allylic a concerted mechanism can operate (Reaction **18-35**).

When R is vinylic it is possible, by using a combination of an alkyllithium and *t*-BuOK, to get migration to the γ carbon (as well as to the α carbon), producing an enolate that, on hydrolysis, gives an aldehyde[449]:

$$CH_2{=}CH{-}CH_2{-}OR' \longrightarrow R'CH_2{-}CH{=}CH{-}OLi \longrightarrow R'CH_2CH_2CHO$$

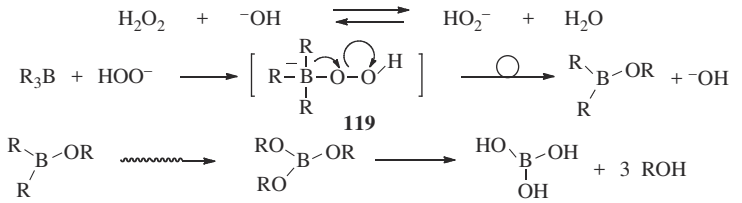
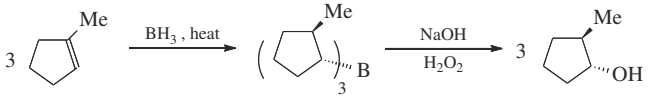
An *aza-Wittig rearrangement* is also known.[450] Other [2,3]-rearrangements are discussed in Reaction **18-35.**

There are no OS references, but see OS **VIII**, 501, for a related reaction.



F. Boron-to-Carbon Migrations[451]

For another reaction involving boron-to-carbon migration, see **10-73**.



18-23 Conversion of Boranes to Alcohols

$$R_3B \xrightarrow[NaOH]{H_2O_2} R\text{-}OH + B(OH)_3$$

Oxidation of trialkylboranes (see Reaction **15-16**) uses NaOH and H_2O_2, which react to give the hydroperoxide anion, (HOO^-). Reaction of the organoborane with basic H_2O_2 (via HOO^-) leads to an ate-complex, and subsequent B → O rearrangement of an alkyl group on boron to a peroxy oxygen, with expulsion of hydroxide, leads to a borate, and then an alcohol after hydrolysis. The proposed mechanism[452] is shown in which a trialkylborane is converted to 3 molar equivalents of the alcohol, along with boric acid.

Using the hydroboration reaction in **15-16**, this procedure converts alkenes to an *anti-Markovnikov* borane, and oxidation leads to the *anti-Markovnikov alcohol*. An example is the conversion of methylcyclopentene to *trans*-2-methylcyclopentanol.[453] Formation of the organoborane proceeds via a cis-addition of B—H, placing the boron trans to the methyl group, and stereoselective oxidation and B → O rearrangement leads to retention of configuration in the alcohol, as shown.

Trialkylboranes can be prepared from alkenes by Reaction **15-16**, and they react with carbon monoxide[454] at 100–125 °C in the presence of ethylene glycol to give the 2-bora-1,3-dioxolanes (**96**), which are easily oxidized (Reaction **12-27**) to tertiary alcohols.[455] The R groups may be primary, secondary, or tertiary, and may be the same or different.[456] Yields are high and the reaction is quite useful, especially for the preparation of sterically hindered alcohols (e.g., tricyclohexylcarbinol, **97** and tri-2-norbornylcarbinol, **98**), which are difficult to prepare by Reaction **16-24**. Heterocycles in which boron is a ring atom react similarly (except that high CO pressures are required), and cyclic alcohols can be obtained from these substrates.[457] The preparation of such heterocyclic boranes was discussed at Reaction **15-16**. The overall conversion of a diene or triene to a cyclic alcohol has been described by H.C. Brown as "stitching" with boron and "riveting" with carbon.

The mechanism has been shown to be intramolecular by the failure to find cross-over products when mixtures of boranes are used.[458] The following scheme, involving three boron-to-carbon migrations, to **99** and then to **100** has been suggested.

The purpose of the ethylene glycol is to intercept the boronic anhydride (**100**), which otherwise forms polymers that are difficult to oxidize. As will be seen in Reaction **18-23** and **18-24**, it is possible to stop the reaction after only one or two migrations have taken place.

$$\text{Method 1} \quad R_3B + CHCl_2OMe \xrightarrow[\text{2. } H_2O_2-NaOH]{\text{1. } LiOCEt_3-THF} R_3COH$$

$$\text{Method 2} \quad R_3B + {}^-CN \xrightarrow{THF} \underset{\mathbf{101}}{R_3B{-}CN} \xrightarrow[\text{2. } NaOH-H_2O_2]{\text{1. excess } (CF_3CO)_2O} R_3COH$$

There are two other methods for achieving the conversion $R_3B \rightarrow R_3COH$, which often give better results: (1) treatment with α,α-dichloromethyl methyl ether and the base lithium triethylcarboxide[459] (2) treatment with a suspension of sodium cyanide in THF

[459] Brown, H.C.; Carlson, B.A. *J. Org. Chem.* ***1973***, *38*, 2422; Brown, H.C.; Katz, J.; Carlson, B.A. *J. Org. Chem.* ***1973***, *38*, 3968.

followed by reaction of the resulting trialkylcyanoborate (**101**) with an excess (>2 equiv) of trifluoroacetic anhydride.[460] All the above migrations take place with retention of configuration at the migrating carbon.[461]

Several other methods for the conversion of boranes to tertiary alcohols are also known.[462]

If the reaction between trialkylboranes and carbon monoxide (**18-23**) is carried out in the presence of water followed by addition of NaOH, the product is a secondary alcohol. If H_2O_2 is added along with the NaOH, the corresponding ketone is obtained instead.[463] Various functional groups (e.g., OAc, COOR, CN) may be present in R without being affected,[464] although if they are in the α or β position relative to the boron atom, difficulties

$$\underset{\textbf{101}}{R_3B^{-}\!-\!CN} \xrightarrow[2.\ H_2O_2\text{-}OH^-]{1.\ (CF_3CO)_2O} RCOR$$

may be encountered. The use of an equimolar amount of trifluoroacetic anhydride leads to the ketone rather than the tertiary alcohol.[465] By this procedure thexylboranes ($RR'R^2B$, where R^2 = thexyl) can be converted to unsymmetrical ketones (RCOR′).[466] Variations of this methodology have been used to prepare optically active alcohols.[467] For another conversion of trialkylboranes to ketones see Reaction **18-26**.[468]

OS **VII**, 427. Also see, OS **VI**, 137.

18-24 Conversion of Boranes to Primary Alcohols, Aldehydes, or Carboxylic Acids

$$R_3B + CO \xrightarrow[2.\ H_2O_2-OH]{1.\ LiBH_4} RCH_2OH$$

$$R_3B + CO \xrightarrow[2.\ H_2O_2-NaH_2PO_4-Na_2PHO_4]{1.\ LiAlH(OMe)_3} RCHO$$

When the reaction between a trialkylborane and carbon monoxide (**18-23**) is carried out in the presence of a reducing agent (e.g., lithium borohydride or potassium triisopropoxyborohydride), the reduction agent intercepts the intermediate (**99**), so that only one boron→carbon migration takes place, and the product is hydrolyzed to a primary alcohol or oxidized to an aldehyde.[469] This procedure wastes two of the three R groups, but this problem can be avoided by the use of B-alkyl-9-BBN derivatives (see Reaction **15-16**).

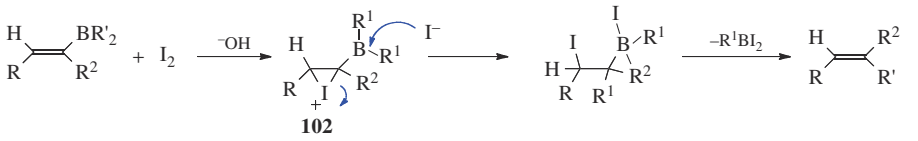
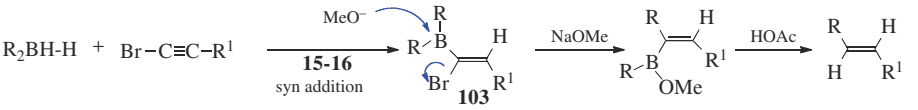
Since only the 9-alkyl group migrates, this method permits the conversion in high yield of an alkene to a primary alcohol or aldehyde containing one more carbon.[470] When B-alkyl-9-BBN derivatives are treated with CO and lithium tri-*tert*-butoxyaluminum hydride,[471] other functional groups (e.g., CN and ester) can be present in the alkyl group without being reduced.[472] Boranes can be directly converted to carboxylic acids by reaction with the dianion of phenoxyacetic acid.[473]

Boronic esters [$RB(OR')_2$] react with methoxy(phenylthio)methyllithium [LiCH(OMe)SPh] to give salts, which, after treatment with $HgCl_2$, and then H_2O_2, yield aldehydes.[474] This synthesis has been made enantioselective, with high ee values (>99%), by the use of an optically pure boronic ester,[475] for example:



18-25 Conversion of Vinylic Boranes to Alkenes



The reaction between trialkylboranes and iodine to give alkyl iodides was mentioned at **12-31**. When the substrate contains a vinylic group, the reaction takes a different course,[476] with one of the R′ groups migrating to the carbon, to give alkenes.[477] The reaction is stereospecific in two senses: (1) if the groups R and R″ are cis in the starting compound, they will be trans in the product; (2) there is retention of configuration within the migrating group R′.[478] Since vinylic boranes can be prepared from alkynes (Reaction **15-16**), this is a method for the addition of R′ and H to a triple bond. If $R^2 = H$, the product is a (*Z*)-alkene. The mechanism is believed to involve an iodonium intermediate, (e.g., **102**) and attack by iodide on boron. When R′ is vinylic, the product is a conjugated diene.[479]

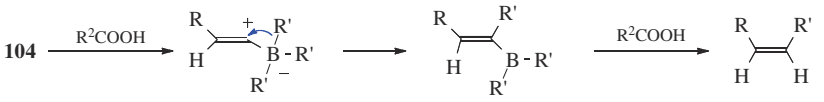
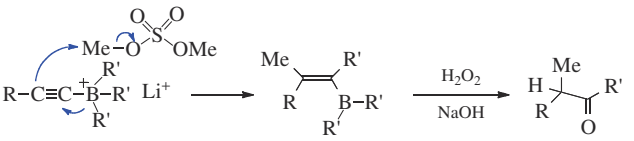
In another procedure, the addition of a dialkylborane to a 1-haloalkyne produces an α-halo vinylic borane (**103**).[480] Treatment of **103** with NaOMe gives the rearrangement shown, and protonolysis of the product produces the (*E*)-alkene.[478] If R is a vinylic group, the product is a 1,3-diene.[481] If one of the groups is thexyl, the other migrates.[482] A combination of both of the procedures described above results in the preparation of trisubstituted alkenes.[483]



18-26 Formation of Alkynes, Alkenes, and Ketones from Boranes and Acetylides



A hydrogen directly attached to a triple-bond carbon can be replaced in high yield by an alkyl or an aryl group, by treatment of the lithium acetylide with a trialkyl- or triarylborane, followed by reaction of the lithium alkynyltrialkylborate (**104**) with iodine.[484] The R′ group may be primary or secondary alkyl as well as aryl, so the reaction has a broader scope than the older Reaction **10-74**.[485] The R group may be alkyl, aryl, or hydrogen, although in the last-mentioned case satisfactory yields are obtained only if lithium acetylide-ethylenediamine is used as the starting compound.[486] Optically active alkynes can be prepared by using optically active thexylborinates (RR^2BOR', R^2 = thexyl, where R is chiral) and $LiC{\equiv}CSiMe_3$.[487] The reaction can be adapted to the preparation of alkenes[488] by treatment of **104** with an electrophile (e.g., propanoic acid[489] or tributyltin chloride).[490] The reaction with Bu_3SnCl produces the (*Z*)-alkene stereoselectively.

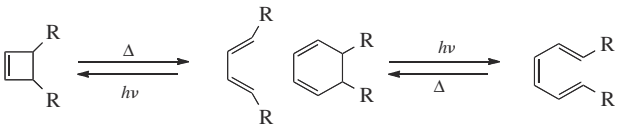
Treatment of **104** with electrophiles (e.g., methyl sulfate, allyl bromide, or triethyloxonium borofluoride), followed by oxidation of the resulting vinylic borane, gives a ketone (illustrated for methyl sulfate)[491]:



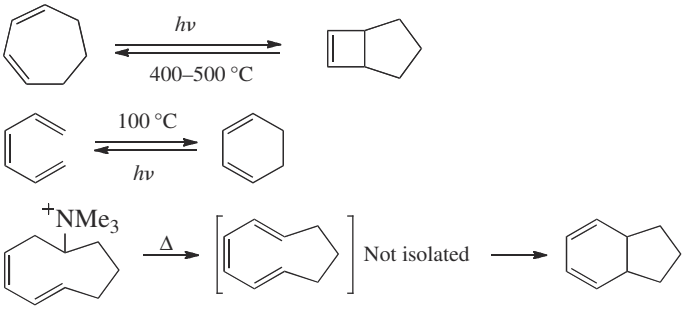
Note that there are reactions that involve N → O rearrangements, including those mediated by silicon.[492]

18.F.ii. Non-1,2 Rearrangements

A. Electrocyclic Rearrangements

18-27 Electrocyclic Rearrangements of Cyclobutenes and 1,3-Cyclohexadienes

(4) *seco*-1/4/Detachment; (4) *cyclo*-1/4/Attachment
(6) *seco*-1,6/Detachment; (6) *cyclo*-1/6/Attachment



Cyclobutenes and 1,3-dienes can be interconverted by treatment with UV light or with heat.[493] These are 4π-electrocyclizations. The thermal reaction is generally not reversible (although exceptions[494] are known), and many cyclobutenes have been converted to 1,3-dienes by heating at temperatures between 100 and 200 °C.[495] Benzocyclobutenes also undergo electrocyclic ring opening,[496] as do benzocyclobutanones.[497] The photochemical conversion can in principle be carried out in either direction, but most often 1,3-dienes are converted to cyclobutenes rather than the reverse, because the dienes are stronger absorbers of light at the wavelengths used.[498] In a similar reaction, 1,3-cyclohexadienes interconvert with 1,3,5-trienes, but in this case the ring-closing process is generally favored thermally and the ring-opening process photochemically, but exceptions are known in both

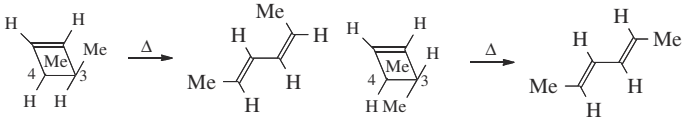
directions.[499] Substituent effects can lead to acceleration of the electrocyclization process.[500] *Torquoselectivity* in cyclobutene ring-opening reaction has been examined.[501]

Examples of these types of reactions include:



Ref. 502

An interesting example of 1,3-cyclohexadiene→1,3,5-triene interconversion is the reaction of norcaradienes to give cycloheptatrienes.[503] This is a 6π-electrocyclization, and it has been catalyzed by Lewis acids.[504] Norcaradienes give this reaction so readily (because they are *cis*-1,2-divinylcyclopropanes, see Reaction **18-32**) that they cannot generally be isolated, though some exceptions are known[505] (see also, **15-64**).

Norcaradiene

These reactions, called *electrocyclic rearrangements*,[506] take place by pericyclic mechanisms. The evidence comes from stereochemical studies, which show a remarkable stereospecificity whose direction depends on whether the reaction is induced by heat or light. For example, it was found for the thermal reaction that *cis*-3,4-dimethylcyclobutene gave only *cis*,*trans*-2,4-hexadiene, while the trans isomer gave only the *trans*–*trans*-diene[507]:

This is evidence for a four-membered cyclic transition state and arises from conrotatory motion about the C-3–C-4 bond.[508] It is called conrotatory because both movements are clockwise (or both counterclockwise). Because both rotate in the same direction, the cis isomer gives the *cis–trans*-diene.[509] The other possibility (*disrotatory* motion) would have one moving clockwise while the other moves counterclockwise; the cis isomer would have given the *cis–cis*-diene (shown) or the *trans–trans*-diene. If the motion had been disrotatory, this would still have been evidence for a cyclic mechanism. If the mechanism were a diradical or some other kind of noncyclic process, it is likely that no stereospecificity of either kind would have been observed. The reverse

reaction is also conrotatory. In contrast, the photochemical cyclobutene: 1,3-diene interconversion is *disrotatory* in either direction.[510] On the other hand, the cyclohexadiene: 1,3,5-triene interconversion shows precisely the opposite behavior. The thermal process is *disrotatory*, while the photochemical process is *conrotatory* (in either direction). These startling results are a consequence of the symmetry rules mentioned in Section **15-60**, the FOM.[511] As in the case of cycloaddition reactions, we will use the FOM and *Möbius–Hückel* approaches.[512]

The Frontier Orbital Method (FOM)[513]

As applied to these reactions, the FOM may be expressed: *A σ bond will open in such a way that the resulting p orbitals will have the symmetry of the highest occupied π orbital of the product*. In the case of cyclobutenes, the HOMO of the product in the thermal reaction is the χ_2 orbital (Fig. 18.1). Therefore, in a thermal process, the cyclobutene must open so that on one side the positive lobe lies above the plane, and on the other side below it. Thus the substituents are forced into conrotatory motion (Fig. 18.2). On the other hand, in the photochemical process, the HOMO of the product is now the χ_3 orbital (Fig. 18.1), and in order for the *p* orbitals to achieve this symmetry (the two plus lobes on the same side of the plane), the substituents are forced into disrotatory motion.

This reaction may be considered from the opposite direction (ring closing). For this direction, the rule is that *those lobes of orbitals that overlap (in the HOMO) must be of the same sign*. For thermal cyclization of butadienes, this requires conrotatory motion

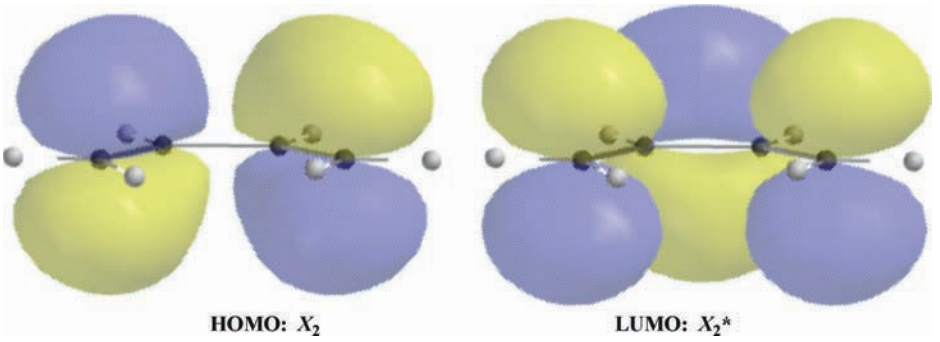

FIG. 18.1. Symmetries of the X_2 and X_3^* orbitals of a conjugated diene

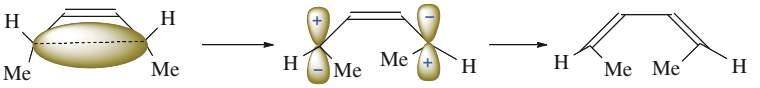

FIG. 18.2. Thermal opening of 1,2-diethylcyclobutene. The two hydrogens and two methyls are forced into conrotatory motion so that the resulting *p*-orbitals have the symmetry of the HOMO of the diene.

(Fig. 18.3). In the photochemical process, the HOMO is the χ_3 orbital, so that disrotatory motion is required for lobes of the same sign to overlap.

The Möbius–Hückel Method

As seen in Reaction **15-60**, the *Möbius–Hückel Method*, a basis set of *p* orbitals is chosen and inspected for sign inversions in the transition state. Figure 18.4 shows a basis set for a 1,3-diene. It is seen that disrotatory ring closing (Fig. 18.4*a*) results in overlap of plus lobes only, while in conrotatory closing (Fig. 18.4*b*) there is one overlap of a plus with a minus lobe. In the first case, there are zero sign inversions, while in the second there is one sign inversion. With zero (or an even number of) sign inversions, the disrotatory transition state is a *Hückel system,* and so is allowed thermally only if the total number of electrons is $4n + 2$ (Sec. **15-60**, the *Möbius–Hückel Method*). Since the total here is 4, the disrotatory process is not allowed. On the other hand, the conrotatory process, with one sign inversion, is a *Möbius*

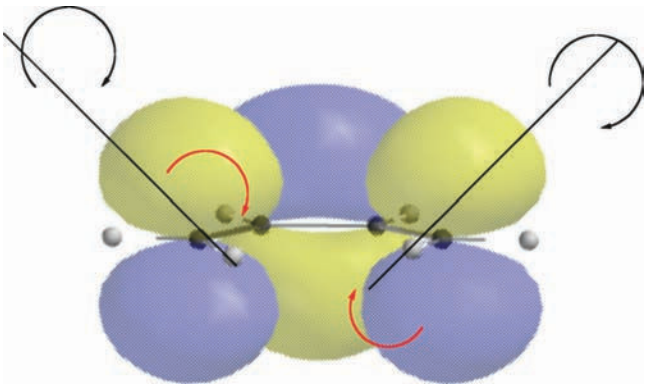

FIG. 18.3. Thermal ring closing of a 1,3-diene. Conrotatory motion is required for two + lobes to overlap.

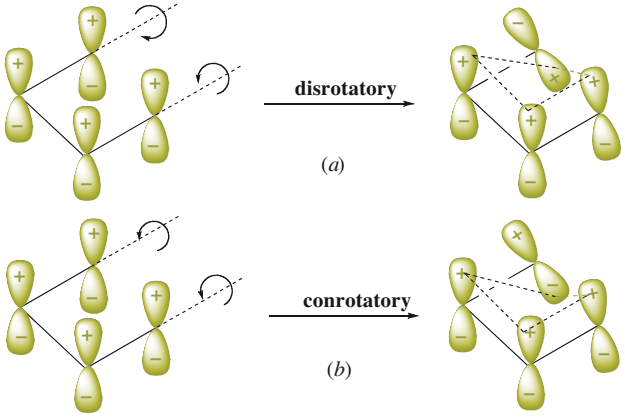

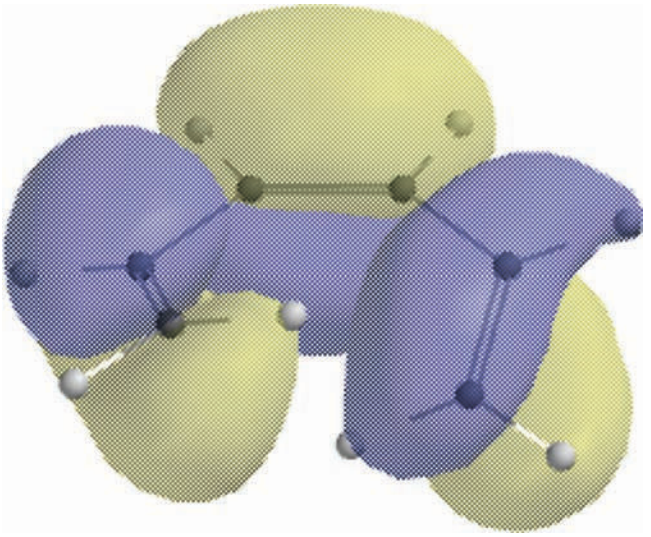

FIG. 18.4. The 1,3-diene–cyclobutene interconversion. The orbitals shown are *not* molecular orbitals, but a basis set of *p* atomic orbitals. (*a*) Disrotatory ring closure gives zero sign inversion. (*b*) Conrotatory ring closure gives one sign inversion. We could have chosen to show any other basis set (another basis set would have two plus lobes above the plane and two below, etc.). This would change the number of sign inversion, but the disrotatory mode would still have an even number of sign inversions, and the conrotatory mode an odd number, whichever basis set was chosen.

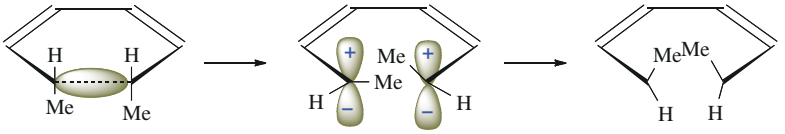
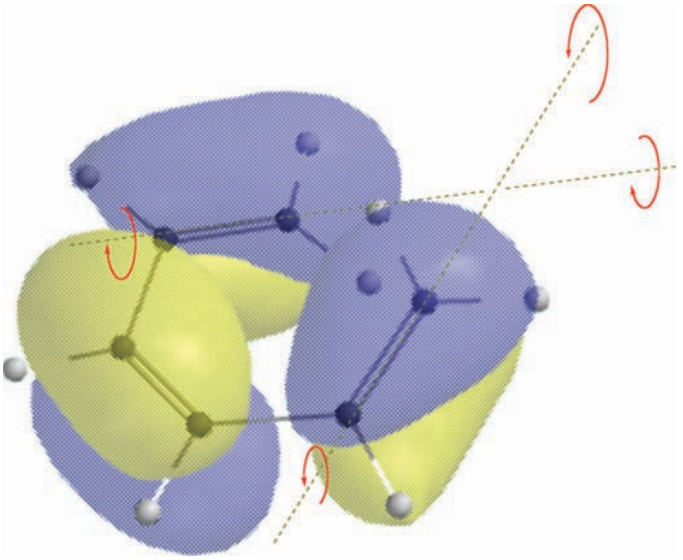


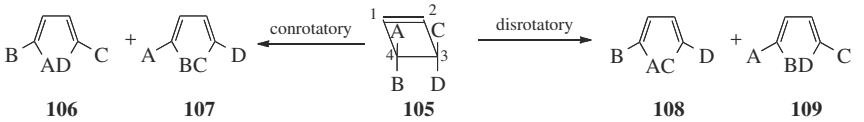
system, which is thermally allowed if the total number is 4*n*. The conrotatory process is therefore allowed thermally. For the photochemical reactions, the rules are reversed: A reaction with 4*n* electrons requires a *Hückel* system, so only the disrotatory process is allowed.

Both the FOM and the *Möbius–Hückel* methods can also be applied to the cyclohexadiene: 1,3,5-triene reaction[514]; in either case the predicted result is that for the thermal process, only the disrotatory pathway is allowed, and for the photochemical process, only the conrotatory. For example, for 1,3,5-hexatriene, the symmetry of the HOMO is



[514] For a discussion of the transition structures and energy, see Zora, M. *J. Org. Chem.* ***2004****, 69*, 1940.

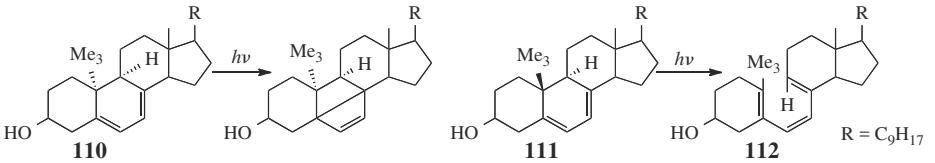
In the thermal cleavage of cyclohexadienes, then, the positive lobes must lie on the same side of the plane, requiring disrotatory motion:



Disrotatory motion is also necessary for the reverse reaction, in order that the orbitals that overlap may be of the same sign:

All these directions are reversed for photochemical processes, because in each case a higher orbital, with inverted symmetry, is occupied.

In the *Möbius–Hückel* approach, diagrams similar to Fig. 18.4 can be drawn for this case. Here too, the disrotatory pathway is a *Hückel* system and the conrotatory pathway a *Möbius* system, but since six electrons are now involved, the thermal reaction follows the Hückel pathway and the photochemical reaction the *Möbius* pathway.

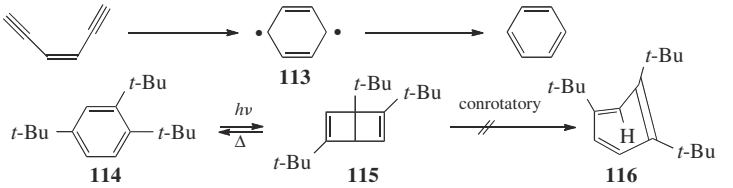


In the most general case, four possible products can arise from a given cyclobutene or cyclohexadiene: two from the conrotatory and two from the disrotatory pathway. For example, conrotatory ring opening of **105** gives either **106** or **107**, while disrotatory opening gives either **108** or **109**. The orbital-symmetry rules indicate when a given reaction will operate by the conrotatory and when by the disrotatory mode, but not which of the two possible conrotatory or disrotatory pathways will be followed. Often, however, it is possible to make such

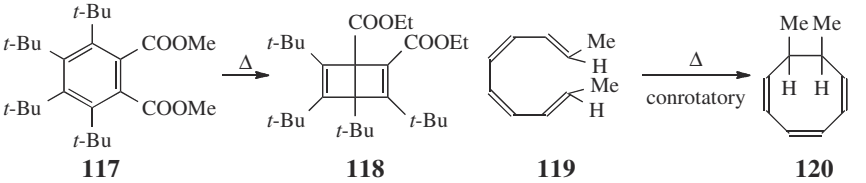
106 **107** **105** **108** **109**

predictions on steric grounds. For example, in the opening of **105** by the disrotatory pathway, **108** arises when groups A and C swing in toward each other (clockwise motion around C-4,

counterclockwise around C-3), while **109** is formed when groups B and D swing in and A and C swing out (clockwise motion around C-3, counterclockwise around C-4). This observation leads to a prediction that when A and C are larger than B and D, the predominant or exclusive product will be **109** rather than **108**. Predictions of this kind have largely been borne out.[515] There is evidence, however, that steric effects[516] are not the only factor, and that electronic effects also play a role, and their role may be even greater.[517] An electron-donating group stabilizes the transition state when it rotates *outward*, because it mixes with the LUMO; if it rotates *inward*, it mixes with the HOMO, destabilizing the transition state.[518] The compound 3-formylcyclobutene provided a test. Steric factors would cause the CHO (an electron-withdrawing group) to rotate outward; electronic effects would cause it to rotate inward. The experiment showed inward rotation.[519]



Cyclohexadienes are of course 1,3-dienes, and in certain cases it is possible to convert them to cyclobutenes instead of to 1,3,5-trienes.[520] An interesting example is found in the pyrocalciferols. Photolysis of the syn isomer (**110**) (or of the other syn isomer, not shown) leads to the corresponding cyclobutene,[521] while photolysis of the anti isomers (one of them is **111**) gives the ring-opened 1,3,5-triene (**112**). This difference in behavior is at first sight remarkable, but is easily explained by the orbital-symmetry rules. Photochemical ring opening to a 1,3,5-triene must be conrotatory. If **110** were to react by this pathway, the product would be the triene **112**, but this compound would have to contain a *trans*-cyclohexene ring (either the methyl group or the hydrogen would have to be directed inside the ring). On the other hand, photochemical conversion to a cyclobutene must be disrotatory, but if **111** were to give this reaction, the product would have to have a trans-fused ring junction. Compounds with such ring junctions are known (Sec. 4.K.iii), but are very strained. Stable *trans*-cyclohexenes are unknown (Sec. 4.Q.iii). Thus, **110** and **111** give the products they do owing to a combination of orbital-symmetry rules and steric influences.



A related process is the *Bergmann cyclization*,[522] where an ene–diyne cyclizes to a biradical (**103**) and then aromatizes as shown. Simply heating the en–diyne will usually lead to aromatization via this pathway.[523] Quinones can be formed via *Bergman*

cyclization[524] and there are other synthetic applications.[525] The role of vinyl substitution has been examined.[526] An *aza-Bergman cyclization* is known.[527]

The 1,3-diene-cyclobutene interconversion can even be applied to benzene rings. For example,[528] photolysis of 1,2,4-tri-*tert*-butylbenzene (**114**) gives 1,2,5-tri-*tert*-butyl [2.2.0]hexadiene (**115**, a *Dewar benzene)*.[529] The reaction owes its success to the fact that once **115** is formed, it cannot, under the conditions used, revert to **114** by either a thermal or a photochemical route. The orbital-symmetry rules prohibit thermal conversion of **115** to **114** by a pericyclic mechanism, because thermal conversion of a cyclobutene to a 1,3-diene must be conrotatory, and conrotatory reaction of **115** would result in a 1,3,5-cyclohexatriene containing one trans double bond (**116**), which is of course too strained to exist. Compound **115** cannot revert to **114** by a photochemical pathway either, because light of the frequency used to excite **114** would not be absorbed by **115**. This is another example of a molecule that owes its stability to the orbital-symmetry rules (see Reaction **15-63**). Pyrolysis of **115** does give **114**, probably by a diradical mechanism.[530] In the case of **117** and **118**, the *Dewar benzene* is actually more stable than the benzene. Compound **117** rearranges to **118** in 90% yield at 120 °C.[531] In this case, thermolysis of the benzene gives the *Dewar benzene* (rather than the reverse), because of the strain of four adjacent *tert*-butyl groups on the ring.

A number of electrocyclic reactions have been carried out with systems of other sizes, [(e.g., conversion of the 1,3,5,7-octatetraene (**119**) to the cyclooctatriene (**120**)].[532] The

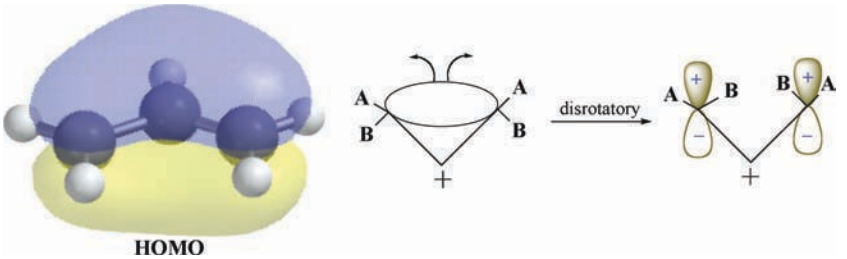
stereochemistry of these reactions can be predicted in a similar manner. The results of such predictions can be summarized according to whether the number of electrons involved in the cyclic process is of the form $4n$ or $4n+2$ (where n is any integer including zero).

	Thermal Reaction	Photochemical Reaction
$4n$	Conrotatory	Disrotatory
$4n+2$	Disrotatory	Conrotatory

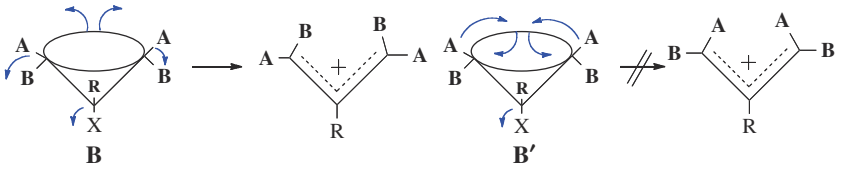
Although the orbital-symmetry rules predict the stereochemical results in almost all cases, it is necessary to recall (Reaction **15-60**, the *Möbius–Hückel* Method) that they only say what is allowed and what is forbidden, but t*he fact that a reaction is allowed does not necessarily mean that the reaction takes plac*e, and if an allowed reaction does take place, it does not *necessarily* follow that a concerted pathway is involved, since other pathways of lower energy may be available.[533] Furthermore, a "forbidden" reaction might still be made to go, if a method of achieving its high activation energy can be found. This was, in fact, done for the cyclobutene–butadiene interconversion (*cis*-3,4-dichlorocyclobutene gave the forbidden *cis*,*cis*- and *trans*,*trans*-1,4-dichloro-1,3-butadienes, as well as the allowed cis, trans isomer) by the use of IR laser light.[534] This is a thermal reaction. The laser light excites the molecule to a higher vibrational level (Sec. 7.A.i), but not to a higher electronic state.

As is the case for $[2+2]$-cycloaddition reactions (**15-63**), certain forbidden electrocyclic reactions can be made to take place by the use of metallic catalysts.[535] An example is the silver ion-catalyzed conversion of tricyclo[4.2.0.$0^{2,5}$]octa-3,7-diene to cyclooctatetraene[536]:



Barrelene anion

This conversion is very slow thermally (i.e., without the catalyst) because the reaction must take place by a disrotatory pathway, which is disallowed thermally.[537] In another example, the major thermal product from the barrelene anion is a rearranged allyl anion that is formed by disrotatory cleavage of the cyclopropyl ring, a formally *Woodward–Hoffmann*-forbidden process.[538]



The ring opening of cyclopropyl cations (Sec. 10.G.i, category 7 and Reaction **18-3**) is an electrocyclic reaction and is governed by the orbital symmetry rules.[539] For this case, the

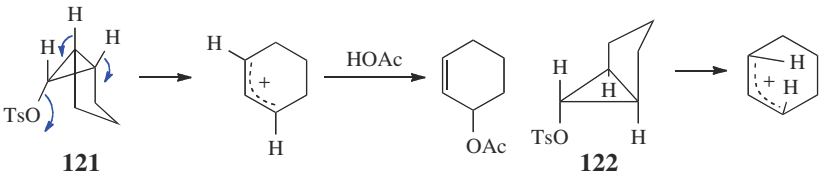
rule is invoked that the σ bond opens in such a way that the resulting *p* orbitals have the symmetry of the highest occupied orbital of the product, in this case,



an allylic cation. Recall that an allylic system has three molecular orbitals (Sec. 2.C, category 3). For the cation, with only two electrons, the highest occupied orbital is the one of lowest energy (**HOMO**). Thus, the cyclopropyl cation must undergo a disrotatory ring opening in order to maintain the symmetry. Note that, in contrast, ring opening of the cyclopropyl *anion* must be conrotatory,[540] since in this case it is the next orbital of the allylic system that is the highest occupied, and this has the opposite symmetry.[541] However, it is difficult to generate a free cyclopropyl cation (Sec. 10.G.i, category 7), and it is likely that in most cases, cleavage of the σ bond is concerted with departure of the leaving group in the original cyclopropyl substrate. This, of course, means that the σ bond provides anchimeric assistance to the removal of the leaving group (an S_N2 type process), and we would expect that such assistance should come from the back side. This has an important effect on the direction of ring opening. The orbital-symmetry rules require that the ring opening is disrotatory, but as seen above, there are two disrotatory pathways and the rules do not indicate which is preferred. But the fact that the σ orbital provides assistance from the backside means that the two substituents that are trans to the leaving group must move *outward*, not inward.[542] Thus, the disrotatory pathway that is followed is the one shown in **B**, not the one shown in **B′**, because the former puts the electrons of the σ bond on the side opposite

that of the leaving group.[543] Strong confirmation of this picture[544] comes from acetolysis of *endo*- (**121**) and *exo*-bicyclo[3,1,0]hexyl-6-tosylate (**112**). The groups trans to the tosylate must move outward. For **121,** this means that the two hydrogen atoms can go outside the

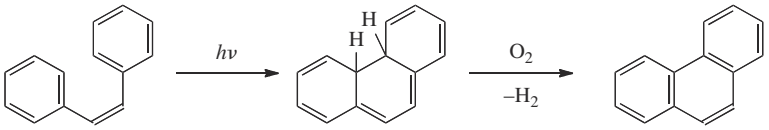
[543] It has been suggested that the pathway shown in **C** is possible in certain cases: Hausser, J.W.; Grubber, M.J. *J. Org. Chem.* ***1972****, 37*, 2648; Hausser, J.W.; Uchic, J.T. *J. Org. Chem.* ***1972****, 37,* 4087.
[544] Also see Reese, C.B.; Shaw, A. *J. Am. Chem. Soc.* ***1970****, 92,* 2566; Dolbier, Jr., W.R.; Phanstiel, O. *Tetrahedron Lett.* ***1988****, 29,* 53, and references cited therein.

framework of the six-membered ring, but for **122** they



are forced to go inside. Consequently, it is not surprising that the rate ratio for solvolysis of **121/122** was found to be $>2.5 \times 10^6$ and that at 150 °C, **122** did not solvolyze at all.[545] This evidence is kinetic. Unlike the cases of the cyclobutene (1,3-diene and cyclohexadiene) 1,3,5-triene interconversions, the direct product here is a cation, which is not stable but reacts with a nucleophile and loses some of its steric integrity in the process, so that much of the evidence has been of the kinetic type rather than from studies of product stereochemistry. However, it has been shown by investigations in superacids (Sec. 5.A.ii), where it is possible to keep the cations intact and to study their structures by NMR, that in all cases studied the cation that is predicted by these rules is in fact formed.[546]

18-28 Conversion of One Aromatic Compound to Another

(6) *cyclo*-de-hydrogen-coupling (Overall transformation)

Stilbenes can be converted to phenanthrenes by irradiation with UV light[547] in the presence of an oxidizing agent, (e.g., dissolved molecular oxygen, $FeCl_3$, or iodine).[548] The reaction is a photochemically allowed conrotatory[549] conversion of a 1,3,5-hexatriene to a cyclohexadiene, followed by removal of two hydrogen atoms by the oxidizing agent. The intermediate dihydrophenanthrene has been isolated.[550] The actual reacting species must be the *cis*-stilbene, but *trans*-stilbenes can often be used, because they are isomerized to the cis isomers under the reaction conditions. The reaction can be extended to the preparation of many fused aromatic systems, for example[551]:

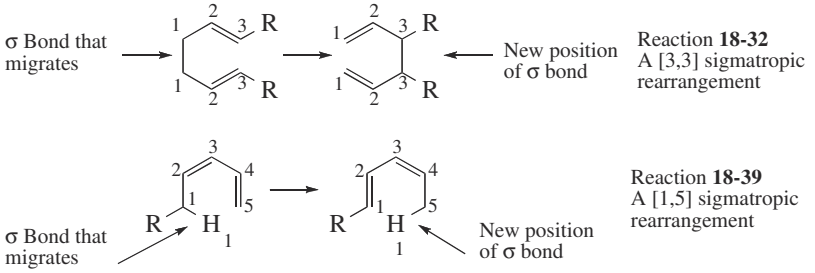
though not all such systems give a reaction.[552] The use of substrates containing heteroatoms (e.g., PhN=NPh) allows the formation of heterocyclic ring systems.

Isomerization of biphenylene to benzo[*a*]pentalene[553] is a well-known benzene ring contraction rearrangement,[554] driven by relief of strain in the four-membered ring. Related to this process is the flash vacuum pyrolysis (FVP) of the alternant polycyclic aromatic hydrocarbon benzo[*b*]biphenylene at 1100 °C, which gives fluoranthene, a nonalternant polycyclic aromatic hydrocarbon, as the major product at 1100 °C in the gas phase.[555] The mechanism used explain that this isomerization involves equilibrating diradicals of 2-phenylnaphthalene, which rearrange by the net migration of a phenyl group to give equilibrating diradicals of 1-phenylnaphthalene, one isomer of which then cyclizes to fluoranthene.

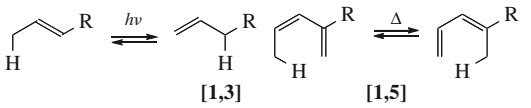


Another transformation of one aromatic compound to another is the *Stone–Wales rearrangement* of pyracyclene (**123**),[556] which is a bond-switching reaction. The rearrangement of bifluorenylidene (**124**) to dibenzo[*g,p*]chrysene (**125**) occurs at temperatures as low as 400 °C and is accelerated in the presence of decomposing iodomethane, a convenient source of methyl radicals.[557] This result suggested a radical rearrangement. This rearrangement is believed to occur by a radical-promoted mechanism consisting of a sequence of homoallyl-cyclopropylcarbinyl rearrangement steps.[558]

123 **124** **125**

B. Sigmatropic Rearrangements

A sigmatropic rearrangement is defined[559] as migration, in an uncatalyzed intramolecular process, of a σ bond, adjacent to one or more π systems, to a new position in a molecule, with the π systems becoming reorganized in the process. Examples are



The *order* of a sigmatropic rearrangement is expressed by two numbers set in brackets: [*i,j*]. These numbers can be determined by counting the atoms over which each end of the

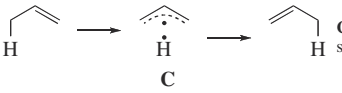
σ bond has moved. Each of the original termini is given the number 1. Thus in the first example above, each terminus of the σ bond has migrated from C-1 to C-3, so the order is [3,3]. In the second example, the carbon terminus has moved from C-1 to C-5, but the hydrogen terminus has not moved at all, so the order is [1,5].

18-29 [1,j]-Sigmatropic Migrations of Hydrogen

1/→3/Hydrogen-migration; 1/→5/Hydrogen-migration



Many examples of thermal or photochemical rearrangements in which a hydrogen atom migrates from one end of a system of π bonds to the other have been reported,[560] although the reaction is subject to geometrical constraints. Isotope effects play a role in sigmatropic rearrangements, and there is evidence for a kinetic silicon isotope effect.[561] Pericyclic mechanisms are involved,[562] and the hydrogen must, in the transition state, be in contact with both ends of the chain at the same time. This means that for [1,5] and longer rearrangements, the molecule must be able to adopt the cisoid conformation. Furthermore, there are two geometrical pathways by which any sigmatropic rearrangement can take place, illustrated for the case of a [1,5]-sigmatropic rearrangement,[563] starting with a substrate of the form **126**, where the migration origin is an asymmetric carbon atom and U ≠ V. In one of the two pathways, the hydrogen moves along the top or bottom face of the π system. This is called *suprafacial migration*. In the other pathway, the hydrogen moves *across* the π system, from top to bottom, or vice versa. This is *antarafacial* migration. Altogether, a single isomer like **126** (different rotamers) can give four products. In a suprafacial migration, H can move across the top of the π system (as drawn above) to give the (*R*,*Z*)-isomer, or it can rotate 180° and move across the bottom of the π system to give the (*S*,*E*)- isomer.[564] The antarafacial migration can similarly lead to two diastereomers, in this case the (*S*,*Z*)- and (*R*,*E*)-isomers.

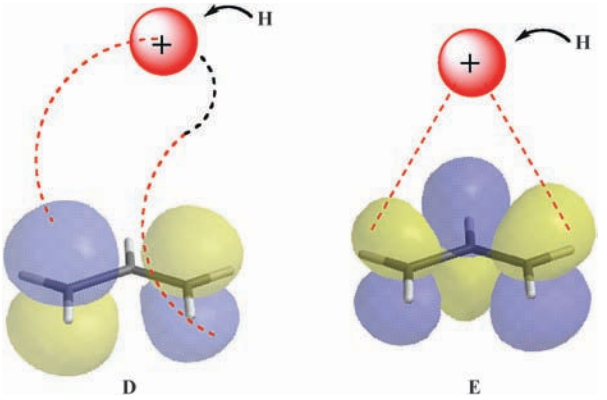
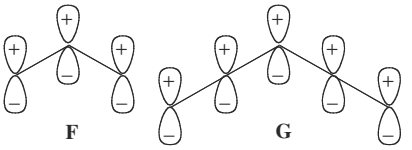
[562] Moss, S.; King, B.T.; de Meijere, A.; Kozhushkov, S.I.; Eaton, P.E.; Michl, J. *Org. Lett.* ***2001****, 3*, 2375.
[563] Note that a [1,5]-sigmatropic rearrangement of hydrogen is also an internal ene synthesis (Reaction **15-20**).
[564] The designations U, V, Y, and Z are arbitrary, so which isomer is(*R*,*Z*) and which is (*S*,*E*) is arbitrary.



In any given sigmatropic rearrangement, only one of the two pathways is allowed by the orbital-symmetry rules; the other is forbidden. To analyze this situation, first use a modified frontier orbital approach.[565] Imagine that in the transition state **C**, the migrating H atom breaks away from the rest of the system, which is treated as if it were a free radical.

C

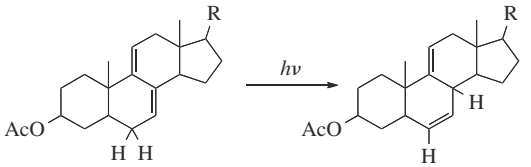


C is an imaginary transition state for a [1,3]-sigmatropic rearrangement

Note that this is not what actually takes place; it is *imagined* in order to analyze the process. In a [1,3]-sigmatropic rearrangement, the imaginary transition state consists of a hydrogen atom and an allyl radical. The latter species (Sec. 2.C, category 3) has three π orbitals, but the only one that is of concern, the HOMO, which, in a thermal rearrangement is **D**. The electron of the hydrogen atom is of course in a 1*s* orbital, which has only one lobe. The rule governing sigmatropic migration of hydrogen is *the H must move from a plus to a plus or from a minus to a minus lobe, of the HOMO; it cannot move to a lobe of opposite sign.*[566] The only way this can happen in a thermal [1,3]-sigmatropic rearrangement is by an antarafacial migration. Consequently, the rule predicts that antarafacial thermal [1,3]-sigmatropic rearrangements are allowed, but the suprafacial pathway is forbidden. However, in a photochemical reaction, promotion of an electron means that **E** is now the HOMO; the suprafacial pathway is now allowed and the antarafacial pathway is forbidden.

D **E**

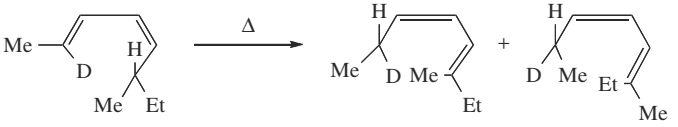
A similar analysis of [1,5]-sigmatropic rearrangements shows that in this case the thermal reaction must be suprafacial and the photochemical process antarafacial. For the general case, with odd-numbered *j*, [1,*j*]-suprafacial migrations are allowed thermally when *j* is of the form $4n + 1$, and photochemically when *j* has the form $4n - 1$; the opposite is true for antarafacial migrations.



F **G**

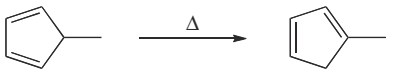
[565] See Woodward, R.B.; Hoffmann, R. *The Conservation of Orbital Symmetry*, Academic Press, NY, ***1970***, pp. 114–140.

[566] This follows from the principle that bonds are formed only by overlap of orbitals of the same sign. Since this is a concerted reaction, the hydrogen orbital in the transition state must overlap simultaneously with one lobe from the migration origin and one from the terminus. It is obvious that both of these lobes must have the same sign.



As expected, the *Möbius–Hückel* method leads to the same predictions. Here, examine the basis set of orbitals shown in **F** and **G** for [1,3]- and [1,5]-rearrangements, respectively. A [1,3]-shift involves four electrons, so an allowed thermal pericyclic reaction must be a *Möbius* system (**15-60**, the *Möbius–Hückel* Method) with one or an odd number of sign inversions. As can be seen in **F**, only an antarafacial migration can achieve this. A [1,5]-shift, with six electrons, is allowed thermally only when it is a *Hückel* system with zero or an even number of sign inversions; hence it requires a suprafacial migration.[567]

The actual reported results bear out this analysis. Thus a thermal [1,3]-migration is allowed to take place only antarafacially, but such a transition state would be extremely strained, and thermal [1,3]-sigmatropic migrations of hydrogen are unknown.[568] On the other hand, the photochemical pathway allows suprafacial [1,3]-shifts, and a few such reactions are known, an example being the photochemical rearrangement of **127** to **128**.[569] Substituents influence the efficacy of the [1,3]-hydrogen shift.[570]



127 **128**

The situation is reversed for [1,5]-hydrogen shifts. In this case, the thermal rearrangements, being suprafacial, are quite common, while photochemical rearrangements are rare.[571] Two examples of the thermal reaction are

Ref. 572

Ref. 573

Note that the first example bears out the stereochemical prediction made earlier. Only the two isomers shown were formed. In the second example, migration can continue around the ring. Migrations of this kind are called *circumambulatory rearrangements*,[574] and such migrations

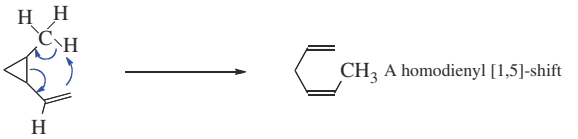
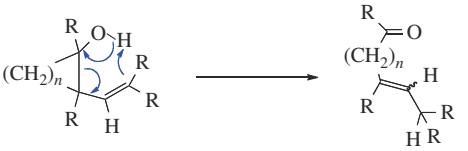
are known for cyclopentadiene,[575] pyrrole, and phosphole derivatives.[576] Geminal bond participation has been observed in pentadienes,[577] the effects of phenyl substituents have been studied,[578] and the kinetics and activation parameters of [1,5]-hydrogen shifts have been examined.[579] The [1,5]-hydrogen shifts are also known with vinyl aziridines.[580] A Ru catalyzed cycloisomerization of en-1-ynes leads to cyclic dienes.[581]



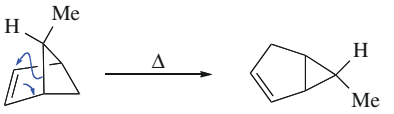
The rare [1,4]-hydrogen transfer has been observed in radical cyclizations.[582] With respect to [1,7]-hydrogen shifts, the rules predict the thermal reaction to be antarafacial.[583] Unlike the case of [1,3]-shifts, the transition state is not too greatly strained, and an example of such rearrangements is the formation of **129** and **130**.[584] Photochemical [1,7]-shifts are suprafacial and, not surprisingly, many of these have been observed.[585]

129 **130**



The orbital symmetry rules also help to explain the unexpected stability of certain compounds (see Reaction **15-63**, preceding Reaction **15-64** and **18-27**, the *Möbius–Hückel* Method). Thus, **130** could, by a thermal [1,3]-sigmatropic rearrangement, easily convert to toluene, which of course is far more stable because it has an aromatic sextet. Yet **130** has been prepared and is stable at dry ice temperature and in dilute solutions.[586]

Analogues of sigmatropic rearrangements in which a cyclopropane ring replaces one of the double bonds are also known, for example,[587]



The reverse reaction has also been reported.[588] 2-Vinylcycloalkanols[589] undergo an analogous reaction, as do cyclopropyl ketones (see **18-33**, preceding **18-34** for this reaction).

18-30 [1,j]-Sigmatropic Migrations of Carbon

[1,3] migration of alkyl

Ref. 590

[1,5] migration of phenyl

Ref. 591

Sigmatropic migrations of alkyl or aryl groups[592] are less common than the corresponding hydrogen migrations.[593] When they do take place, there is an important difference. Unlike a hydrogen atom, whose electron is in a 1*s* orbital with only one lobe, a carbon free radical has its odd electron in a *p* orbital that has *two lobes of opposite sign*. Therefore, if the imaginary transition states for this case are drawn (see above), a thermal suprafacial [1,5]-process (Fig. 18.5) is observed, and symmetry can be conserved only if the migrating carbon moves in such a way that the lobe that was originally attached to the π system remains attached to the π system.

This can happen only if configuration is *retained within the migrating group*. On the other hand, thermal suprafacial [1,3]-migration (Fig. 18.6) *can* take place if the migrating carbon switches lobes. If the migrating carbon was originally bonded by its minus lobe, it must now use its plus lobe to form the new C—C bond. Thus, configuration in the migrating group will be *inverted*. From these considerations, suprafacial [1,*j*]-sigmatropic rearrangements in which carbon is the migrating group should always be allowed, both thermally and photochemically, but thermal [1,3]-migrations[594] will proceed with inversion and thermal [1,5]-migrations with retention of configuration within the migrating group. More generally, suprafacial [1, *j*]-migrations of carbon in systems where $j = 4n - 1$ proceed with inversion thermally and retention photochemically, while systems where $j = 4n + 1$ show the opposite behavior. Where antarafacial migrations take place, all these predictions are of course reversed.

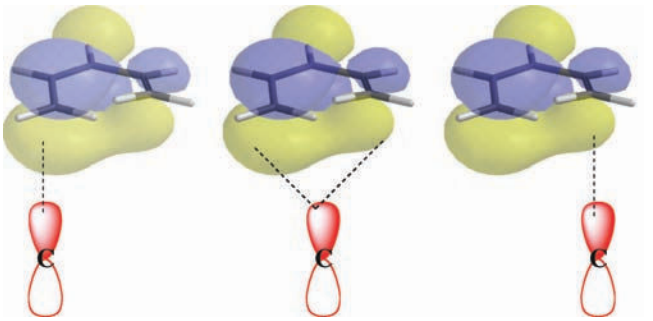

FIG. 18.5. Hypothetical orbital movement for a thermal [1,5]-sigmatropic migration of carbon. To move from one negative lobe, the migrating carbon uses only its own negative lobe, retaining its configuration.

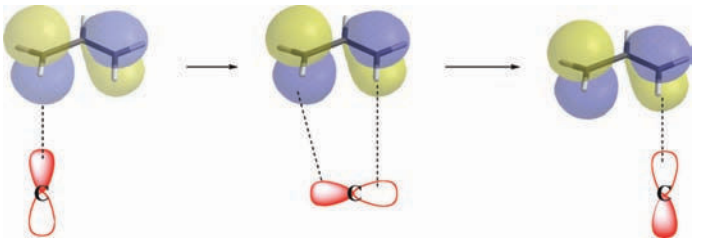

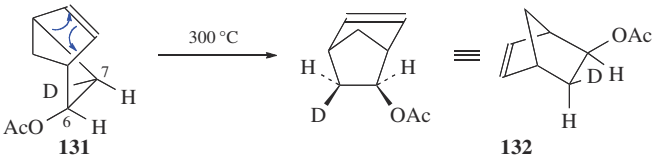

FIG. 18.6. Hypothetical orbital movement for a thermal [1,3]-sigmatropic migration of carbon. The migrating carbon moves a negative to a positive lobe, requiring it to switch its own bonding lobe from negative to positive, inverting its configuration.

The first laboratory test of these predictions was the pyrolysis of deuterated *endo*-bicyclo[3.2.0]hept-2-en-6-yl acetate (**131**), which gave the *exo*-deuterio-*exo*-norbornyl acetate (**132**).[595] Thus, as predicted by the orbital symmetry rules, this thermal suprafacial [1,3]-sigmatropic reaction took place with complete inversion at C-7. Similar results have been obtained in a number of other cases.[596] However, similar studies of the pyrolysis of the parent hydrocarbon of **131**, labeled with D at C-6 and C-7, showed that while most of the product was formed with inversion at C-7, a significant fraction (11–29%) was formed with retention.[597] Other cases of lack of complete inversion are also known.[598] A diradical mechanism has been invoked to explain such cases.[599] There is strong evidence for a radical mechanism for some [1,3]-sigmatropic rearrangements.[600]

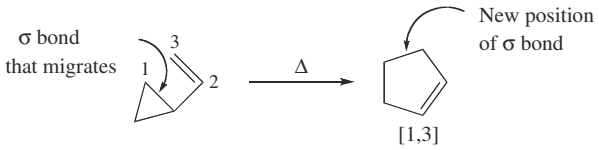
Photochemical suprafacial [1,3]-migrations of carbon have been shown to proceed with retention, as predicted.[601]

131 **132**

Although allylic vinylic ethers generally undergo [3,3]-sigmatropic rearrangements (Reaction **18-33**), they can be made to give the [1,3] kind, to give aldehydes, for example,



by treatment with $LiClO_4$ in diethyl ether.[602] In this case, the C—O bond undergoes a 1,3-migration from the O to the end vinylic carbon. When the vinylic ether is of the type $ROCR'{=}CH_2$, ketones (RCH_2COR') are formed. There is evidence that this [1,3]-sigmatropic rearrangement is not concerted, but involves dissociation of the substrate into ions.[602]

Thermal suprafacial [1,5]-migrations of carbon have been found to take place with retention,[603] but also with inversion.[604] A diradical mechanism has been suggested for the latter case.[604]

Simple nucleophilic, electrophilic, and free radical 1,2-shifts can also be regarded as sigmatropic rearrangements (in this case, [1,2]-rearrangements). As previously discussed (see discussion in introductory section preceding 18.A) similar principles applied to such rearrangements show that nucleophilic 1,2-shifts are allowed, but the other two types are forbidden unless the migrating group has some means of delocalizing the extra electron or electron pair. The mechanism of the forbidden [3*s*,5*s*]-sigmatropic shift has been examined.[605]

18-31 Conversion of Vinylcyclopropanes to Cyclopentenes

The thermal expansion of a vinylcyclopropane to a cyclopentene ring[606] is a special case of a [1,3]-sigmatropic migration of carbon, although it can also be considered an internal

[$_{\pi}2 + _{\sigma}2$]-cycloaddition reaction (see **15-63**). It is known as a *vinylcyclopropane rearrangement*.[607] The reaction has been carried out on many vinylcyclopropanes bearing various substituents in the ring[608] or on the vinyl group and has been extended to 1,1-dicyclopropylethene[609] and (both thermally[610] and photochemically[611]) to vinylcyclopropenes. This

rearrangement can be catalyzed by Rh and Ag compounds, and has been used to form rings.[612] Two competing reactions are the homodienyl [1,5]-shift (if a suitable H is available, see **18-29**), and simple cleavage of the cyclopropane ring, leading in this case to a diene (see **18-3**).

Flash vacuum pyrolysis of the trimethylsilyl ether of cyclopropylcarbinyl alcohols gives ring expanded ketones.[613] Various heterocyclic analogues[614] are also known, as in the rearrangement of aziridinyl amides (**133**).[615] Cyclopropyl ketones can be treated with tosylamine and a Zr catalyst, which converts the imine formed *in situ* to a pyrroline.[616] *N*-Cyclopropylimines undergo rearrangement to cyclic imines (pyrrolines) under photochemical conditions.[617] *P*-Vinyl phosphiranes (the P analogue of cyclopropanes with P in the ring) under a similar rearrangement, and the mechanism has been studied.[618]

133

Vinylcyclobutanes can be converted to cyclohexenes,[619] but larger ring compounds do not generally give the reaction.[620] Tricyclo[4.1.0.0^{2,5}]heptanes rearrange to give nonconjugated cycloheptadienes.[621] The bicyclo[2.1.0]pentane derivatives undergo this reaction.

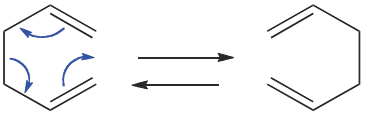
The reaction rate has also been greatly increased by the addition of a one-electron oxidant tris-(4-bromophenyl)aminium hexafluoroantimonate ($Ar_3N\bullet^+$ SbF_6^-, Ar = *p*-bromophenyl).[622] This reagent converts the substrate to a cation radical, which undergoes ring expansion much faster.[623]

The mechanisms of these ring expansions are not certain. Both concerted[624] and diradical[625] pathways have been proposed,[626] and it is possible that both pathways operate, in different systems.



For the conversion of a vinylcyclopropane to a cyclopentene in a different way, see OS **68**, 220.

18-32 The Cope Rearrangement

(3/4/)→(1/6/)-*sigma*-Migration

When 1,5-dienes are heated, a [3,3]-sigmatropic rearrangement known as the *Cope rearrangement* (not to be confused with the *Cope elimination* Reaction, **17-9**) occurs to generate an isomeric 1,5-diene.[627] When the diene is symmetrical about the 3,4-bond, the reaction gives a product identical with the starting material[628]:

Therefore, a *Cope rearrangement* can be detected only when the diene is not symmetrical about this bond. Any 1,5-diene gives the rearrangement; for example, 3-methyl-1,5-hexadiene heated to 300 °C gives 1,5-heptadiene.[629] However, the reaction takes place more easily (lower temperature required) when there is a group on the C-3 or C-4 with leads to the new double bond being substituted. The reaction is reversible[630] and produces an equilibrium mixture of the two 1,5-dienes, which is *richer in the thermodynamically*

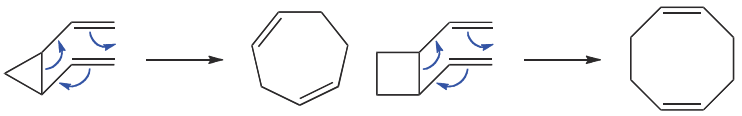
more stable isomer. However, the equilibrium can be shifted to the right for 3-hydroxy-1,5-dienes,[631] because the product tautomerizes to the ketone or aldehyde:

Oxy-Cope

This reaction of 3-hydroxy-1,5-dienes is called the *oxy-Cope rearrangement*,[632] and has proved highly useful in synthesis.[633] The *oxy-Cope rearrangement* is greatly accelerated (by factors of 10^{10}–10^{17}) if the alkoxide is used rather than the alcohol (the *anionic oxy-Cope rearrangement*),[634] where the direct product is the enolate ion, which is hydrolyzed to the ketone. A metal-free reaction using a phosphazene base has been reported.[635] The silyloxy-*Cope rearrangement* has proven to be quite useful.[636] An antibody-catalyzed *oxy-Cope reaction* is known,[637] and the mechanism and origins of catalysis for this reaction have been studied.[638] Sulfur substituents also lead to rate enhancement of the *oxy-Cope rearrangement*.[639] Note that *2-oxonia Cope rearrangements* have been implicated in *Prins cyclization* reactions (**16-54**).[640] A highly diastereoselective *oxonia-Cope rearrangement* proceeded using a chiral aldehyde with a chiral conjugated ester.[641]

Anionic-oxy-Cope



aza-Cope rearrangements are also known.[642] There is an enantioselective *aza-Cope rearrangement*.[643] There is also a 1,2-*oxaza-Cope rearrangement*. Involving esters and alkyl nitrites.[644] In *amino-Cope rearrangements*, the solvent plays a role in the regioselectivity of the reaction.[645] It has been suggested that this latter reaction does not proceed solely by a concerted [3.3]-sigmatropic rearrangement.[646]

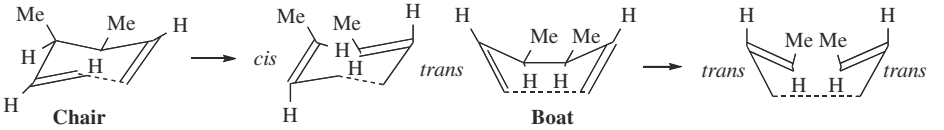
The 1,5-diene system may be inside a ring or part of an allenic system[647] (the example shown illustrates both of these situations).[648] However, the reaction does not take place when one of the double bonds is part of

an aromatic system (e.g., 4-phenyl-1-butene).[649] When the two double bonds are in vinylic groups attached to adjacent ring positions, the product is a ring four carbons larger. This has been applied to divinylcyclopropanes and divinylcyclobutanes, as shown.[650] Indeed, *cis*-1,2-divinylcyclopropanes give this rearrangement so rapidly

that they generally cannot be isolated at room temperature,[651] but exceptions are known.[652] Note that divinyloxiranes, divinylphosphiranes, and divinylthiiranes undergo similar rearrangements.[653] When heated, 1,5-diynes are converted to 3,4-dimethylenecyclobutenes (**134**).[654] A rate-determining *Cope rearrangement* is followed by a very rapid electrocyclic (**18-27**) reaction.



134

The interconversion of 1,3,5-trienes and cyclohexadienes (in Reaction **18-27**) is very similar to the *Cope rearrangement*, but in **18-27**, the 3,4-bond goes from a double to a single bond rather than from a single bond to no bond. Like [2 + 2]-cycloadditions (Reaction **15-63**), *Cope rearrangements* of simple 1,5-dienes can be catalyzed by certain transition metal compounds. For example, the addition of a Pd catalyst causes the reaction to take place at room temperature.[655]

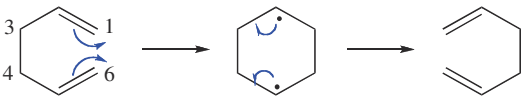
As indicated with the arrows, the mechanism of the uncatalyzed *Cope rearrangement* is a simple six-centered pericyclic process.[656] Since the mechanism is so simple, it has been possible to study some rather subtle points, among them the question of whether the six-membered transition state is in the boat or the chair form.[657] For the case of 3,4-dimethyl-1,5-hexadiene, it was demonstrated conclusively that the transition state is in the chair form. This was shown by the stereospecific nature of the reaction: The meso isomer gave the cis–trans product, while the (±) diastereomer gave the *trans–trans*-diene.[658] If the transition state is in the chair form (taking the meso isomer, e.g.), one methyl must be "axial" and the other "equatorial" and the product must be the

cis–trans-alkene. There are two possible boat forms for the transition state of the meso isomer. One leads to a trans–trans product; the other to a *cis–cis*-alkene. For the (±) pair, the predictions are just the opposite: There is just one boat form, and it leads to the *cis–trans*-alkene, while one chair form ("diaxial" methyls) leads to the cis–cis product and the other ("diequatorial" methyls) predicts the trans–trans product. Thus the nature of the products obtained demonstrates that the transition state is a chair and not a boat.[659] While 3,4-dimethyl-1,5-hexadiene is free to assume either the chair or boat (it prefers the chair), other compounds are not so free. Thus 1,2-divinylcyclopropane (see above) can react *only* in the boat form, demonstrating that such reactions are possible.[660]



Because of the nature of the transition state[661] in the pericyclic mechanism, optically active substrates with a stereogenic carbon at C-3 or C-4 transfer the chirality to the product (see Reaction **18-33** for an example in the mechanistically similar *Claisen rearrangement*).[662] There are many examples of asymmetric [3,3]-sigmatropic rearrangements.[663]

Not all *Cope rearrangements* proceed by the cyclic six-centered mechanism.[664] Thus *cis*-1,2-divinylcyclobutane (see above) rearranges smoothly to 1,5-cyclooctadiene, since the geometry is favorable. The trans isomer also gives this product, but the main product is 4-vinylcyclohexene (resulting from Reaction **18-31**). This reaction can be rationalized as proceeding by a diradical mechanism (see **135**),[665] although it is possible that at least part of the cyclooctadiene produced comes from a prior epimerization of the *trans*- to the *cis*-divinylcyclobutane followed by *Cope rearrangement* of the latter.[666]

It has been suggested that another type of diradical two-step mechanism may be preferred by some substrates.[667] Indeed, a nonconcerted *Cope rearrangement* has been reported.[668] In this pathway,[669] the 1,6-bond is formed before the 3,4-bond breaks:

This is related to the *Bergman cyclization* that was introduced in Reaction **18-27**.

It was pointed out earlier that a *Cope rearrangement* of the symmetrical 1,5-hexadiene gives 1,5-hexadiene. This is a *degenerate Cope rearrangement* (Sec. 18.A.ii). Bicyclo[5.1.0]octadiene (**136**) undergoes a similar rearrangement.[670] At room temperature, the NMR spectrum of this compound is in accord with the structure shown on the left. At 180 °C, it is converted by a *Cope reaction* to a compound equivalent to itself. The interesting thing is that at 180 °C the NMR spectrum shows that what exists is an equilibrium mixture of the two

136 **136**

structures. That is, at this temperature the molecule rapidly (faster than 10^3 times per second) changes back and forth between the two structures. This is called *valence tautomerism* and is quite distinct from resonance, even though only electrons shift[671] (see Sec. 2.N for other types of tautomerism). The positions of the nuclei are not the same in the two structures. Molecules like **136** that exhibit valence tautomerism (in this case, at

180 °C) are said to have *fluxional* structures. It may be recalled that *cis*-1,2-divinylcyclopropane does not exist at room temperature because it rapidly rearranges to 1,4-cycloheptadiene (see above), but in **136** the *cis*-divinylcyclopropane structure is frozen into the molecule in both structures. Several other compounds with this structural feature are also known. Of these, *bullvalene* (**137**) is especially interesting. The *Cope rearrangement* shown for **137** changes the position of the cyclopropane ring from 4,5,10 to 1,7,8. But the molecule could also have undergone rearrangements to put this ring at 1,2,8 or 1,2,7. Any of these could then undergo several *Cope*

137

rearrangements. In all, there are $\frac{10!}{3}$ or >1.2 million tautomeric forms, and the cyclopropane ring can be at any three carbons that are adjacent. Since each of these tautomers is equivalent to all the others, this has been called an infinitely degenerate *Cope rearrangement*. Bullvalene has been synthesized and its ^{1}H NMR spectrum was determined.[672] At −25 °C, there are two peaks with an area ratio of 6 : 4. This is in accord with a single nontautomeric structure. The six protons are the vinylic protons and the four protons are the allylic ones. But at 100 °C, the compound shows only one NMR peak, indicating that the compound rapidly interchanges its structure among 1.2 million equivalent forms.[673] The ^{13}C NMR spectrum of bullvalene also shows only one peak at 100 °C.[674]

138

139 **140**

Another compound for which degenerate *Cope rearrangements* result in equivalence for all the carbons is *hypostrophene* (**138**).[675] In the case of the compound *barbaralane* (**139**)[676] (bullvalene in which one CH=CH has been replaced by a CH_2), there are only 2 equiv tautomers.[677] However, NMR spectra indicate that even at room temperature a rapid interchange of both tautomers is present, although by about −100 °C this has slowed

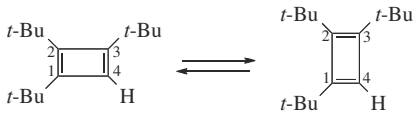
to the point where the spectrum is in accord with a single structure. In the case of *semibullvalene* (**140**) (barbaralane in which the CH_2 has been removed), not only is there a rapid interchange at room temperature, but even at −110 °C.[678] Compound **140** has the lowest energy barrier of any known compound capable of undergoing the *Cope rearrangement*.[679]



141 **142** Oxepin Benzene oxide

The molecules taking part in a valence tautomerization need not be equivalent. Thus, NMR spectra indicate that a true valence tautomerization exists at room temperature between the cycloheptatriene (**141**) and the norcaradiene (**142**).[680] In this case, one isomer (**142**) has the *cis*-1,2-divinylcyclopropane structure, while the other does not. In an analogous interconversion, benzene oxide[681] and oxepin exist in a tautomeric equilibrium at room temperature.[682]

Bullvalene and hypostrophene are members of a group of compounds all of whose formulas can be expressed by the symbol $(CH)_{10}$.[683] Many other members of this group are known. Similar groups of $(CH)_n$ compounds exist for other even-numbered values of "*n*".[685] For example, there are 20 possible $(CH)_8$[684] compounds,[685] and five possible $(CH)_6$ compounds,[686] all of which are known: benzene, prismane (Sec. 4.Q.i), Dewar benzene (see Reaction **18-27**, the *Möbius–Hückel Method*), bicyclopropenyl,[687] and benzvalene.[688]

An interesting example of valence tautomerism is the case of 1,2,3-tri-*tert*-butylcyclobutadiene (Sec. 2.K.ii). There are two isomers, both rectangular, and ^{13}C NMR spectra show that they exist in a dynamic equilibrium, even at −185 °C.[689]

18-33 The Claisen Rearrangement[690]

Allylic aryl ethers, when heated, rearrange to *o*-allylphenols in a reaction called the *Claisen rearrangement*.[691] If both ortho positions are filled, the allylic group migrates to the para position (this is often called the *para-Claisen rearrangement*).[692] There is no reaction when the para and both ortho positions are filled. Migration to the meta position has not been observed. In the ortho migration, the allylic group always undergoes an allylic shift. That is, as shown above, a substituent α to the oxygen is now γ to the ring (and vice versa). On the other hand, in the para migration there is never an allylic shift: The allylic group is found exactly as it was in the original ether. Compounds with propargylic groups (i.e., groups with a triple bond in the appropriate position) do not generally give the corresponding products.

The mechanism is a concerted pericyclic [3,3]-sigmatropic rearrangement[693] and accounts for all these facts. For the ortho rearrangement,

Evidence is the lack of a catalyst, the fact that the reaction is first order in the ether, the absence of cross-over products when mixtures are heated, and the presence of the allylic shift, which is required by this mechanism. The allylic shift for the ortho rearrangement (and the absence of one for the para) has been demonstrated by ^{14}C labeling, even when no substituents are present. Studies of the transition state geometry have shown that, like the *Cope rearrangement*, the *Claisen rearrangement* usually prefers a chair-like transition state.[694] A *retro-Claisen rearrangement* is known and its mechanism has been examined.[695]

When the ortho positions have no hydrogen, a second [3,3]-sigmatropic migration (a *Cope reaction*) follows:

and the migrating group is restored to its original structure. Intermediates of structure **143** have been trapped by means of a *Diels–Alder reaction* (**15-60**).[696] The rearrangement of aryl allyl ethers is facilitated by Ag–KI in hot acetic acid,[697] and by $AlMe_3$ in water.[698] A solid-phase reaction of polymer-bound substrate undergoes the *Claisen rearrangement* with microwave irradiation.[699]

Allylic ethers of enols (allylic vinylic ethers, **144**) also undergo the *Claisen rearrangement*[700]; in fact, it was discovered with these compounds first.[701] In these cases of course, the final tautomerization does not take place even when $R' = H$, since there is no aromaticity to restore, and ketones are more stable than enols.[702] Catalytic *Claisen rearrangements* of allyl vinyl ethers are well known.[703] The use of water as solvent accelerates the reaction.[704] Microwave induced reactions on silica gel[705] and in ionic liquids[706] are known The mechanism is similar to that with allylic aryl ethers.[707] In the presence of a chiral Cu complex, *Claisen rearrangements* proceed with good enantioselectivity.[708] *N*-Heterocyclic carbenes catalyzed an enantioselective *Claisen rearrangement*.[709] A chiral hydrogen-bond donor has been used for enantioselective *Claisen rearrangements*.[710] A chiral allylic ether gave an enantioselective *Claisen rearrangement* with an Ir catalyst.[711]

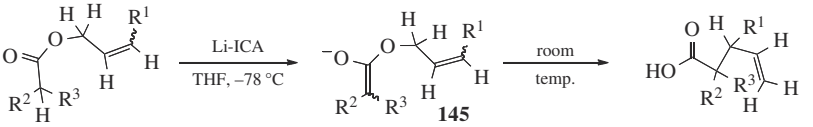
Since the *Claisen rearrangement* mechanism does not involve ions, it should not be greatly dependent on the presence or absence of substituent groups on the ring.[712] This is the case. Electron-donating groups increase the rate and electron-withdrawing groups decrease it, but the effect is small, with the *p*-amino compound reacting only ~10–20 times faster than the *p*-nitro compound.[713] However, solvent effects[714] are greater: Rates varied over a 300-fold range when the reaction was run in 17 different solvents.[715] An especially good solvent is trifluoroacetic acid, in which the reaction can be carried out at room temperature.[716] Most *Claisen rearrangements* are performed without a catalyst, but $AlCl_3$ or BF_3 are sometimes used.[717] In this case, it may become a *Friedel–Crafts reaction*, with the mechanism no longer cyclic,[718] and ortho, meta, and para products may be obtained.

Allyl allene ethers undergo a *Claisen rearrangement* when heated in DMF to give the expected diene with a conjugated aldehyde unit.[719] Butenolides with a β-allylic ether unit undergo *Claisen rearrangement–Conia reaction*[720] cascade to give an oxaspiroheptane with β-keto lactone comprising the five-membered ring.[721] Allylic esters of β-keto acids undergo a *Claisen rearrangement* in what is known as the *Carroll rearrangement*[722] (also called the *Kimel–Cope rearrangement*[723]), and the reaction can be catalyzed by a Ru complex.[724] An asymmetric *Carroll rearrangement* was catalyzed by a chiral Pd complex.[725]



Heating an allylic alcohol with *N,N*-dimethylacetamide dimethyl acetal yields a transient intermediate, and subsequent *Claisen rearrangement* gives an amide in a sequence that is known as the *Eschenmoser variant* or the *Eschenmoser–Claisen rearrangement*.[726] This reaction has also been called the *Meerwein–Eschenmoser Claisen rearrangement*.[727] An enantioselective version has been reported using a chiral Pd complex.[728]

The enolate anions (**145**) of allylic esters (formed by treatment of the esters with LICA) rearrange to γ,δ-unsaturated acids.[729] Alternatively, the silylketene acetal $[R^3R^2C{=}C(OSiR_3)OCH_2CH{=}CHR^1]$ may be used instead of **145**.[730] This rearrangement also proceeds at room temperature. By either procedure, the reaction is called the *Ireland–*

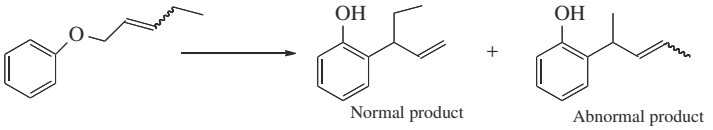
Claisen rearrangement.[731] Note the presence of the negative charge in **145**. As with the *oxy-Cope rearrangement* (in Reaction **18-34**), negative charges generally accelerate the *Claisen reaction*,[732] although the extent of the acceleration can depend on the identity of the positive counterion.[733] The reaction proceeds with good syn selectivity in many cases.[734] The *Ireland–Claisen rearrangement* has been made enantioselective by converting **145** to an enol borinate in which the boron is attached to a chiral group.[735] The *Ireland–Claisen rearrangement* can be done with amide derivatives also.[736]

As just mentioned, asymmetric *Claisen rearrangement* reactions are well known.[737] Chiral Lewis acids have been designed for this purpose.[738] In general, asymmetric [3,3]-sigmatropic rearrangements are well known.[739]

145



A number of analogues of the *Claisen rearrangement* are known, for example, rearrangement of $ArNHCH_2CH{=}CH_2$,[740] of *N*-allylic enamines $(R_2C{=}CRNRCR_2CR{=}CR_2)$[741] of allylic imino esters $[RC(OCH_2CH{=}CH_2){=}NR]$[742] (these have often been rearranged with transition metal catalysts[743]), and of $RCH{=}NRCHRCH_2CH{=}CH_2$. These rearrangements of nitrogen-containing compounds can be called *aza-Claisen rearrangements,*[744] but are sometimes called *aza-Cope rearrangements*,[745] as described in Reaction **18-32**. A Pd catalyzed *aza-Claisen* has been reported.[746] An important contribution to this variation is the rearrangement of

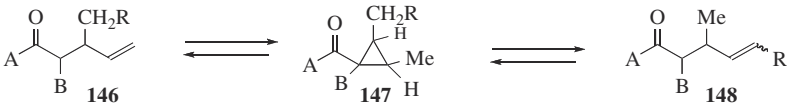
trichloroacetimidate derivatives of prochiral (*Z*)-2-alken-1-ols, usually with a Pd catalyst, to give chiral allylic esters.[747] There is a catalytic enantioselective *aza-Cope rearrangement*.[748] A so-called *amine-Claisen rearrangement* was reported for *N*-allyl indoles, when heated in the presence of $BF_3{\bullet}OEt_2$.[749] An *azo-Cope* rearrangement, $CH_2{=}CHCR_2'){CR_2}'N{=}NAr \rightarrow R_2'C{=}CHCH_2NArN{=}CR_2{}^2$, has been reported.[750] In a related reaction, allylic phorphorimidates undergo [3,3]-sigmatropic rearrangement.[751]

The conversion of allylic aryl thioethers, ($ArSCH_2CH{=}CH_2$) to *o*-allylic thiophenols is not feasible, because the latter are not stable,[752] but react to give bicyclic compounds.[753] However, many allylic vinylic sulfides do give the rearrangement (the *thio-Claisen rearrangement*).[754] Allylic vinylic sulfones (e.g., $H_2C{=}CRCH_2{-}SO_2{-}CH{=}CH_2$) rearrange, when heated in the presence of ethanol and pyridine, to unsaturated sulfonate salts ($CH_2{=}CRCH_2CH_2CH_2SO_3^-$), produced by reaction of the reagents with the unstable sulfene intermediates $CH_2{=}CRCH_2CH_2CH{=}SO_2$.[755] Allylic vinylic sulfoxides rapidly rearrange at room temperature or below.[756] Chiral vinyl sulfoxides undergo *Claisen rearrangement* with good enantioselectivity.[757]

Ethers with an alkyl group in the γ position (ArO—C—C=C—R systems) sometimes give abnormal products, with the β carbon becoming attached to the ring[758]:



It has been established that these abnormal products do not arise directly from the starting ether, but are formed by a further rearrangement of the normal product[759]:

This rearrangement, which has been called an *enolene rearrangement*, a *homodienyl* [1,5]-*sigmatropic hydrogen shift* (see Reaction **18-29**), and a [1,5]-*homosigmatropic rearrangement*, involves a shift of three electron pairs over *seven* atoms. It has been found that this "abnormal" *Claisen rearrangement* is general and can interconvert the enol forms of systems of the types **146** and **147** through the cyclopropane intermediate (**148**).[760]

A = H, R, Ar, OR, and so on B = H, R, Ar, COR, COAr, COOR, and so on

18-34 The Fischer Indole Synthesis

When arylhydrazones of aldehydes or ketones are treated with a catalyst, elimination of ammonia takes place and an indole is formed, in the *Fischer indole synthesis*.[761] Zinc chloride is a commonly used catalyst, but dozens of others, including other metal halides, proton and Lewis acids, and certain transition metals have also been used. Microwave irradiation has been used to facilitate this reaction.[762] The reaction has been done using an $AlCl_3$ complex as an ionic liquid,[763] and solid-phase *Fischer indole syntheses* are known.[764] Aniline derivatives react with α-diazoketones, in the presence of a Rh catalyst, to give indoles as well.[765] Arylhydrazones are easily prepared by the treatment of aldehydes or ketones with phenylhydrazine (Reaction **16-2**) or by aliphatic diazonium coupling (Reaction **12-7**). However, it is not necessary to isolate the arylhydrazone. The aldehyde or ketone can be treated with a mixture of phenylhydrazine and the catalyst; this is now common practice. In order to obtain an indole, the aldehyde or ketone must be of the form $RCOCH_2R'$ (R = alkyl, aryl, or hydrogen). Vinyl ethers (e.g., dihydrofuran) serve as an aldehyde surrogate when treated with phenylhydrazine and a catalytic amount of aq H_2SO_4 to give an 3-substituted indole.[766]

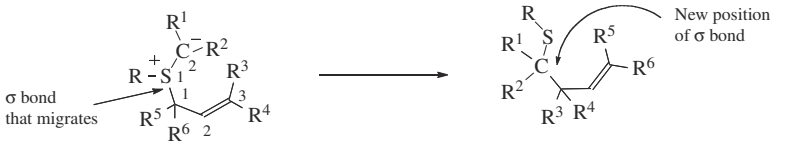
At first glance, the reaction does not seem to be a rearrangement. However, the key step of the mechanism[767] is a [3,3]-sigmatropic rearrangement[768]:



There is much evidence for this mechanism, for example, (1) the isolation of **153**,[769] (2) the detection of **152** by ^{13}C and ^{15}N NMR,[770] (3) the isolation of side products that could only have come from **151**,[771] and (4) ^{15}N-labeling experiments showing that it was the nitrogen farther from the ring that is eliminated as ammonia.[772] The main function of the catalyst seems to be to speed the conversion of **149** to **150**. The reaction can be performed without a catalyst.

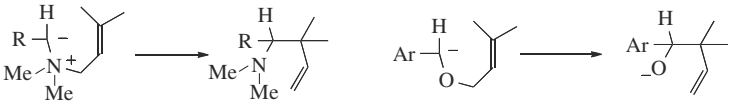
18-35 [2,3]-Sigmatropic Rearrangements



(2/*S*-3/)→(1/5/)-*sigma*-Migration

Sulfur ylids bearing an allylic group are converted to unsaturated sulfides on heating.[773] This is a concerted [2,3]-sigmatropic rearrangement[774] and has also been demonstrated for the analogous cases of nitrogen ylids[775] and the conjugate bases of allylic ethers (in the last case it is called a *[2,3]-Wittig rearrangement*).[776] It has been argued that the *[2,3]-Wittig rearrangement* demands severe deformation of the molecule in order to proceed.[777] It has been shown that SmI_2 induces a *[2,3]-Wittig rearrangement*.[778] The reaction has been

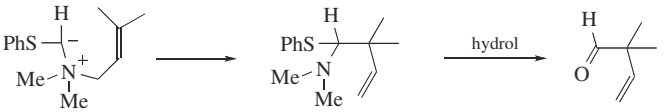
extended to certain other systems,[779] even to an all-carbon system.[780]



Treatment of an α-(*N*-allylic amino) ketone with NaH led to 2-allylic α-amino ketones via a [2,3]-rearrangement.[781] In the presence of a chiral ligand on nitrogen,[781] or with a chiral additive,[782] good asymmetric induction is possible. Vinylaziridines undergo [2.3]-sigmatropic rearrangement.[783]

Since the reactions involve migration of an allylic group from a sulfur, nitrogen, or oxygen atom to an adjacent negatively charged carbon atom, they are special cases of the *Stevens or Wittig rearrangements* (**18-21** and **18-22**). However, in this case the migrating group *must* be allylic (in **18-21** and **18-22** other groups can also migrate). Thus, when the migrating group is allylic, there are two possible pathways: (1) the radical-ion or ion-pair mechanisms (**18-21** and **18-22**) and (2) the concerted pericyclic [2,3]-sigmatropic rearrangement. These are easily distinguished since the latter always involves an allylic shift (as in the *Claisen rearrangemen*t), while the former pathway does not.

Of these reactions, the *[2,3]-Wittig rearrangement* in particular has often been used as a means of transferring chirality. The product of this reaction has potential stereogenic centers at C-3 and C-4 (if $R^5 \neq R^6$), and if the starting ether is optically active because of a stereogenic center at C-1, the product may be optically active as well. Many examples are known in which optically active ethers were converted to a product that was optically active because of chirality at C-3, C-4, or both.[784] If a suitable stereogenic center is present in R^1 (or if a functional group in R^1 can be so converted), then stereocontrol over three contiguous stereogenic centers can be achieved. Stereocontrol of the new double bond (*E* or *Z*) has also been accomplished.

If an OR or SR group is attached to the negative carbon, the reaction becomes a method for the preparation of β,γ-unsaturated aldehydes, because the product is easily hydrolyzed.[785]

Another [2,3]-sigmatropic rearrangement converts allylic sulfoxides to rearranged allylic alcohols by treatment with a thiophilic reagent (e.g., trimethyl phosphite).[786] This is the *Mislow–Evans rearrangement*. In this case, the migration is from sulfur to oxygen. [2,3]-Oxygen-to-sulfur migrations are also known.[787] The *Sommelet–Hauser rearrangement* discussed in Reaction **13-31** is also a [2,3]-sigmatropic rearrangement.

OS **VIII**, 427.

18-36 The Benzidine Rearrangement

Hydrazobenzene **154**

When hydrazobenzene is treated with acids, it rearranges to give ~70% 4,4′-diaminobiphenyl (**154**, benzidine) and ~30% 2,4′-diaminobiphenyl. This reaction is called the *benzidine rearrangement* and is general for *N,N*′-diarylhydrazines.[788] Usually, the major product is the 4,4′-diaminobiaryl, but four other products may also be produced: the 2,4′-diaminobiaryl, already referred to, the 2,2′-diaminobiaryl, and the *o*- and *p*-arylaminoanilines (called *semidines*). The 2,2′- and *p*-arylaminoaniline compounds are formed less often and in smaller amounts than the other two side products. Usually, the 4,4′-diaminobiaryl predominates, except when one or both para positions of the diarylhydrazine are occupied. However, the 4,4′-diamine may still be produced even if the para positions are occupied. If SO_3H, CO_2H, or Cl (but not R, Ar, or NR_2) is present in the para position, it may be ejected. With dinaphthylhydrazines, the major products are not the 4,4′-diaminobinaphthyls, but the 2,2′ isomers. Another side reaction is disproportionation to $ArNH_2$ and ArN=NAr. For example, *p,p*′-$PhC_6H_4NHNHC_6H_4Ph$ gives 88% disproportionation products at 25 °C.[789]

The mechanism has been exhaustively studied and several mechanisms have been proposed.[790] At one time, it was believed that NHAr broke away from ArNHNHAr and became attached to the para position to give the semidine, which then went on to product. The fact that semidines could be isolated lent this argument support, as did the fact that this would be analogous to the rearrangements considered in Chapter 11 (Reaction **11-28**–**11-32**). However, this theory was proved incorrect when it was discovered that semidines could not be converted to benzidines under the reaction conditions. Cleavage into two

independent pieces (either ions or radicals) has been ruled out by many types of cross-over experiments, which always showed that the two rings of the starting material are in the product; that is, ArNHNHAr′ gives no molecules (of any of the five products) containing two Ar groups or two Ar′ groups, and mixtures of ArNHNHAr and Ar′NHNHAr′ give no molecules containing both Ar and Ar′. An important discovery was the fact that, although the reaction is always first order in substrate, it can be either first[791] or second[792] order in $[H^+]$. With some substrates the reaction is entirely first order in $[H^+]$, while with others it is entirely second order in $[H^+]$, regardless of the acidity. With still other substrates, the reaction is first order in $[H^+]$ at low acidities and second order at higher acidities. With the latter substrates fractional orders can often be observed,[793] because at intermediate acidities, both processes take place simultaneously. These kinetic results seem to indicate that the actual reacting species can be either the monoprotonated substrate $ArNHNH_2Ar$ or the diprotonated $ArNH_2NH_2Ar$.

Most of the proposed mechanisms[794] attempted to show how all five products could be produced by variations of a single process. An important breakthrough was the discovery that the two main products are formed in entirely different ways, as shown by isotope-effect studies.[795] When the reaction was run with hydrazobenzene labeled with ^{15}N at both nitrogen atoms, the isotope effect was 1.022 for formation of **154**, but 1.063 for formation of 2,4′-diaminobiphenyl. This showed that the N—N bond is broken in the rate-determining step in both cases, but the steps themselves are obviously different. When the reaction was run with hydrazobenzene labeled with ^{14}C at a para position, there was an isotope effect of 1.028 for formation of **154**, but essentially no isotope effect (1.001) for formation of 2,4′-diaminobiphenyl. This can only mean that for **154** formation of the new C—C bond *and* breaking of the N—N bond both take place in the rate-determining step; in other words, the mechanism is concerted. The following [5.5]-sigmatropic rearrangement accounts for this[796]:

The diion **155** was obtained as a stable species in superacid solution at −78 °C by treatment of hydrazobenzene with $FSO_3H—SO_2$ (SO_2ClF).[797] Although the results just given were obtained with hydrazobenzene, which reacts by the diprotonated pathway, monoprotonated substrates have been found to react by the same [5,5]-sigmatropic mechanism.[798]

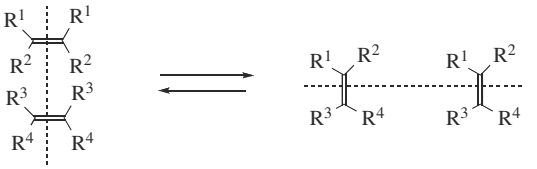
Some of the other rearrangements in this section are also sigmatropic. Thus, formation of the *p*-semidine takes place by a [1,5]-sigmatropic rearrangement,[799] and the conversion of 2,2′-hydrazonaphthalene to 2,2′-diamino-1,1′-binaphthyl by a [3,3] sigmatropic rearrangement.[800]

2,4′-Diaminobiphenyl is formed by a completely different mechanism, though the details are not known. There is rate-determining breaking of the N—N bond, but the C—C bond is not formed during this step.[801] The formation of the *o*-semidine also takes place by a nonconcerted pathway.[802] Under certain conditions, benzidine rearrangements have been found to go through radical cations.[803]

C. Other Cyclic Rearrangements

18-37 Metathesis of Alkenes (Alkene or Olefin Metathesis)[804]



Alkene metathesis

$$CH_3CH{=}CHCH_2CH_3 \xrightarrow[WCl_6-EtOH]{EtAlCl_2} CH_3CH{=}CHCH_3 + CH_3CH_2CH{=}CHCH_2CH_3$$

When alkenes are treated with certain catalysts they are converted to other alkenes in a reaction in which one set of alkylidene groups ($R^1R^2C{=}$) have become interchanged with other alkylidene groups ($R^3R^4C{=}$) by a process schematically illustrated by the equilibrium reaction shown below. In an early example shown above, 2-pentene (either cis, trans, or a cis–trans mixture) is converted to a mixture of ~50% 2-pentene, 25% 2-butene, and 25% 3-hexene. Nowadays, superior catalysts and experimental procedures have made this reaction synthetically useful (see below). The reaction is reversible[805] and the alkene starting material and products exist in equilibrium, so the same mixture can be obtained by starting with equimolar quantities of 2-butene and 3-hexene.[806] The reaction is called *metathesis* of alkenes or *alkene metathesis* (*olefin metathesis*).[807] In general, the reaction can be applied to a single unsymmetrical alkene, giving a mixture of itself and two other

alkenes, or to a mixture of two alkenes, in which case the number of different molecules in the product depends on the symmetry of the reactants. In the example, a mixture of $R^1R^2C{=}CR^1R^2$ and $R^3R^4C{=}CR^3R^4$ gives rise to only one new alkene ($R^1R^2C{=}CR^3R^4$), while in the most general case, the reaction of two alkenes ($R^1R^2C{=}CR^3R^4$ and $R^5R^6C{=}CR^7R^8$) can give a mixture of 10 alkenes: the original $2 + 8$ new ones. In early work, W, Mo,[808] or Re complexes were used, and with simple alkenes the proportions of products are generally statistical,[809] which limited the synthetic utility of the reaction since the yield of any one product is low. In some cases, one alkene may be more or less thermodynamically stable than the rest, so that the proportions are not statistical in all cases.

It is possible to shift the equilibrium to favor certain products. For example, 2-methyl-1-butene gives rise to ethylene and 3,4-dimethyl-3-hexene. By allowing the gaseous ethylene to escape, the yield of 3,4-dimethyl-3-hexene can be raised to 95%.[810] This example shows that it is possible to tailor the substrate to include two terminal alkenes that lead to ethylene as a product, whose escape from the reaction drives the equilibrium to product.

The development of better catalysts has revolutionized this reaction,[811] making it one of the most important methods available for modern synthesis. Both homogeneous[812] and heterogeneous[813] catalysts have been used for this reaction. Of the many homogeneous catalysts, Ru complexes are the most important,[814] and important heterogeneous catalysts include oxides of Mo, W, and Re deposited on alumina or silica gel.[815] The major breakthrough in these catalysts was the development of catalysts that are relatively air stable. Three important catalysts are metal carbene complexes **156**[816] and **157**[817] (*Grubbs catalyst I and II;* Mes = mesityl, respectively), and **158** (the *Shrock catalyst*).[818]

Catalyst **157** can be generated *in situ* from air stable precursors.[819]

156

157

158

The synthetic importance[820] of ring-closing and ring-opening metathesis reactions has, in part, led to the ongoing development of new catalysts.[821] Catalysts have been developed that are compatible with both water and methanol.[822] The reaction is compatible with the presence of other functional groups[823] (e.g., other alkene units,[824] carbonyl units,[825] the alkene unit of conjugated esters,[826] butenolides[827] and other lactones,[828] amines,[829] amides,[830] sulfones,[831] phosphine oxides,[832] sulfonate esters,[833] and sulfonamides,[834] see **149**).[835] Ether groups,[836] including vinyl ethers,[837] vinyl halides,[838] vinyl silanes,[839] vinyl sulfones,[840] allylic ethers,[841] and thioethers[842] are also compatible.

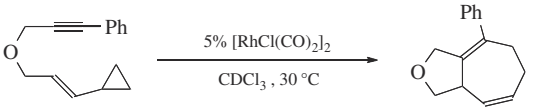
Asymmetric ring-closing metathesis reactions have been reported,[843] and chiral metathesis catalysts are continually being developed.[844] The enantioselective synthesis of bicyclic lactams from dienyl lactams used a chiral Mo catalyst.[845] Asymmetric ring-opening metathesis has also been reported.[846]



Recyclable catalysts have been developed,[847] and the reaction has been done in ionic liquids,[848] supercritical CO_2[849] (Sec. 9.D.ii), and in aqueous media.[850] Microwave-induced ring-closing metathesis[851] and also cross-metathesis reactions[852] are known. Polymer-bound Ru[853] and Mo catalysts[854] have been used, and catalyst **157** has been immobilized on PEG.[855] Efficient methods have been developed for the removal of Ru byproducts from metathesis reactions that include the use of a scavenger resin,[856] and removal by aqueous extraction.[857]

By choice of the proper catalyst, the reaction has been applied to terminal and internal alkenes, straight chain or branched. The effect of substitution on the ease of reaction is $CH_2{=}{>}RCH_2CH{=}{>}R_2CHCH{=}{>}R_2C{=}$.[858] Note that isomerization of the C=C unit can occur after metathesis,[859] but methods have been developed to prevent this, including addition of 2,6-dichlorobenzoquinone.[860] Cross-metathesis[861] (or symmetrical homo-metathesis[862]) of alkenes to give new alkenes can be accomplished. Monosubstituted alkenes react faster than disubstituted alkenes.[863] A double metathesis reaction of a diene (also called *domino*[864] or *tandem metathesis*[865]) with conjugated aldehydes has been

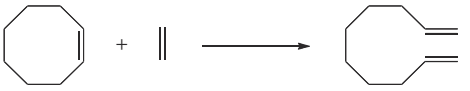
reported,[866] and a triple metathesis was reported to for a dihydropyran with two dihydropyran substituents.[867] Cross-metathesis of vinylcyclopropanes leads to an alkene with two cyclopropyl substituents.[868] Vinylcyclopropane-alkyne metathesis reactions have been reported.[869] Cyclic alkenes can be opened, usually with polymerization using metathesis catalysts. Ring-opening metathesis generates dienes from cyclic alkenes.[870] Allenes undergo a metathesis reaction to give symmetrical allenes.[871] An interesting variation reacts an α,ω-diene with a cyclic alkene. The combination of ring-opening metathesis and ring-closing cross-metathesis leads to ring expansion to give a macrocyclic nonconjugated diene.[872] Note that an alkane metathesis reaction is known.[873]

Dienes can react intermolecularly or intramolecularly.[874] Intramolecular reactions generate rings, including small rings,[875] usually alkenes or dienes. Alkene metathesis can be used to form very large rings, including 21-membered lactone rings.[876] Diynes undergo both cross-metathesis and ring-closing metathesis.[877] Diynes can also react intramolecularly to give large-ring alkynes.[878] Metathesis with vinyl-cyclopropyl-alkynes is also known, producing a ring-expanded product (see **159**).[879] Vinyl halides undergo metathesis reactions.[880]

159



Two cyclic alkenes react to give dimeric dienes,[881] for example,

With many catalysts, the products can then react with additional monomers and with each other, so that polymers are produced, and the cyclic dienes are obtained only in low yield.

The reaction between a cyclic and a linear alkene can give a ring-opened diene[882]:

The reaction has also been applied to internal alkynes[883]:

$$2\,RC{\equiv}CR' \rightleftharpoons RC{\equiv}CR + R'C{\equiv}CR'$$

and some success has been reported for terminal triple bonds.[884] As noted above, molecules with a terminal alkene and a terminal alkyne react quite well (ene-yne metathesis).[885] Intramolecular reactions of a double bond with a triple bond are known[886] and a tetracyclic tetraene has been prepared from a poly-yne-diene.[887] Cross-metathesis of terminal alkynes and terminal alkenes (en-ynes)[888] to give a diene has also been reported.[889] Enyne metathesis generates 1,3-dienes.[890]

The generally accepted mechanism is a chain mechanism,[891] involving the intervention of a metal–carbene complex (**160** and **161**)[892] and a four-membered ring containing a metal[893] (**162**–**165**).[894] In the cross-metathesis reaction shown as an example, $R_2C{=}CR_2$ reacts with $R^1{}_2C{=}CR^1{}_2$ in the presence of a metal catalyst (M). Initial reaction with the catalyst leads to the two expected metal carbenes, (**160** and **161**). Metal carbene (**161**) can react with both alkenes to form metallocyclobutanes **162** and **163**. Each of these intermediates loses the metal to form the alkenes, the product of metathesis ($R_2C{=}CR^1{}_2$) and one of the original alkenes. In a likewise manner, **160** reacts with each alkene to form metallocyclobutanes **164** and **165**, which decomposes to $R_2C{=}CR_2$ and the metathesis product. It has been shown that the phosphine-containing methylidene complexes decompose to methylphosphonium salts,[895]

18-38 Metal-Ion-Catalyzed σ-Bond Rearrangements

Many highly strained cage molecules undergo rearrangement when treated with metallic ions [e.g., Ag^+, Rh(I), or Pd(II)].[896] The bond rearrangements observed can be formally classified into two main types: (*Type 1*)

[2 + 2]-ring openings of cyclobutanes and (Type *2*) conversion of a bicyclo[2.2.0] system to a bicyclopropyl system. The molecule cubane supplies an example of each type

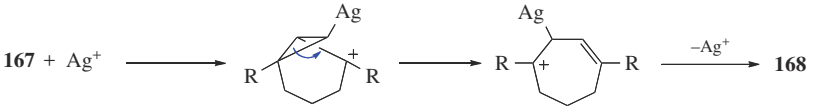
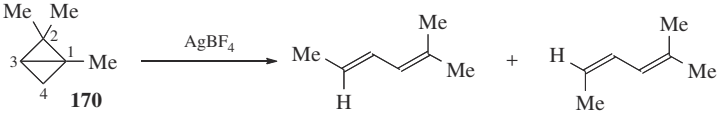
(see above). Treatment with Rh(I) complexes converts cubane to tricyclo[4.2.0.$0^{2,5}$]octa-3,7-diene (**166**),[897] an example of type 1, while Ag^+ or Pd(II) causes the second type of reaction, producing cuneane.[898] Other examples are the conversion of **167** to **168**, and formation of **159**, the 9,10-dicarbomethyoxy derivative of *snoutane* (pentacyclo[3.3.2.$0^{2,4}$.$0^{3,7}$.$0^{6,8}$]decane).

Type 1



167 **168** Ref. 899

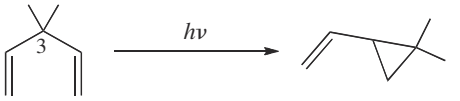
Type 2[900]



169 Ref. 901

The mechanisms of these reactions are not completely understood, although relief of strain undoubtedly supplies the driving force. The reactions are thermally forbidden by the orbital-symmetry rules, and the role of the catalyst is to provide low-energy pathways so that the reactions can take place. Type 1 reactions are the reverse of the catalyzed [2 + 2] ring closures discussed at Reaction **15-63**. The following mechanism, in which Ag^+ attacks one of the edge bonds, has been suggested for the conversion of **167** to **168**.[902]

Simpler bicyclobutanes can also be converted to dienes, but in this case the products usually result from cleavage of the central bond and one of the edge bonds.[903] For example, treatment of **170** with $AgBF_4$,[904]



170

or [(π-allyl)PdCl]$_2$[905] gives a mixture of the two dienes shown, resulting from a formal cleavage of the C-1—C-3 and C-1—C-2 bonds (note that a hydride shift has taken place). Dienes can also be converted to bicyclobutanes under photochemical conditions.[906]

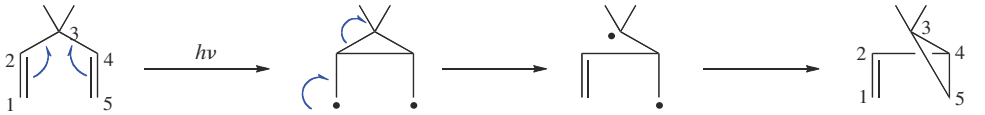
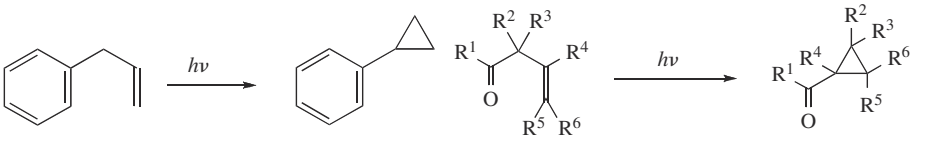
18-39 The Di-π-methane and Related Rearrangements

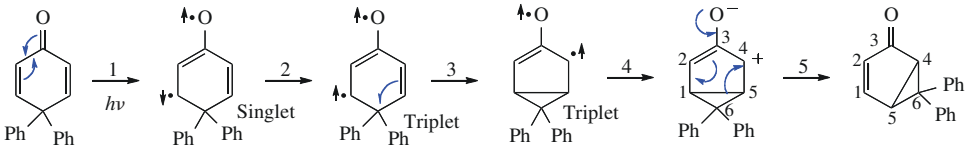


Di-π-methane rearrangement

1,4-Dienes carrying alkyl or aryl substituents on C-3[907] can be photochemically rearranged to vinylcyclopropanes in a reaction called the *di-π-methane rearrangement*.[908] An example is conversion of **171** to **172**.[909] For most 1,4-dienes, it is only the singlet excited state that gives the reaction; triplet states generally take other pathways.[910] For unsymmetrical dienes, the reaction is regioselective. For example, **173** gave **174**, not **175**:[911]



The mechanism can be described by the diradical pathway given[912] (the C-3 substituents act to stabilize the radical), although the species shown are not necessarily intermediates, but may represent transition states. It has been shown, for the case of certain substituted substrates, that configuration is retained at C-1 and C-5 and inverted at C-3.[913]



The reaction has been extended to allylic benzenes[914] (in this case C-3 substituents are not required), to β,γ-unsaturated ketones[915] (the latter reaction, which is called the *oxa-di-*

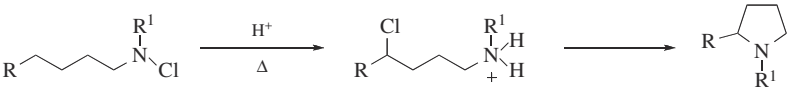
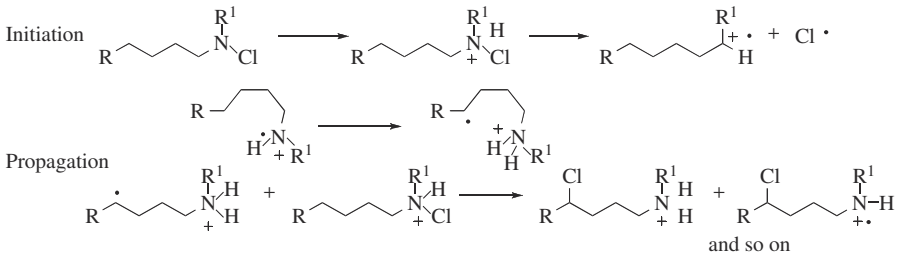
π-methane rearrangement,[916] generally occurs only from the triplet state), to β,γ-unsaturated imines,[917] and to triple-bond systems.[918]

When photolyzed, 2,5-cyclohexadienones can undergo a number of different reactions, one of which is formally the same as the di-π-methane rearrangement.[919] In this reaction, photolysis of the substrate **176** gives the bicyclo[3.1.0]hexenone (**181**). Although the reaction is formally the same (note the conversion of **171** to **172**),



176 **177** **178** **179** **180** **181**

the mechanism is different from that of the di-π-methane rearrangement, because irradiation of a ketone can cause an $n \rightarrow \pi*$ transition, which is of course not possible for a diene lacking a carbonyl group. The mechanism[920] in this case has been formulated as proceeding through the excited triplet states **178** and **179**. In step 1, the molecule undergoes an $n \rightarrow \pi*$ excitation to the singlet species **177**, which cross to the triplet **178**. Step 3 is a rearrangement from one excited state to another. Step 4 is a $\pi* \rightarrow n$ electron demotion (an intersystem crossing from $T_1 \rightarrow S_0$, see Sec. 7.A.vi, category 4). The conversion of **180** to **181** consists of two 1,2-alkyl migrations (a one-step process would be a 1,3-migration of alkyl to a carbocation center): The old C-6—C-5 bond becomes the new C-6—C-4 bond and the old C-6—C-1 bond becomes the new C-6—C-5 bond.[921]



2,4-Cyclohexadienones also undergo photochemical rearrangements, but the products are different, generally involving ring opening.[922]

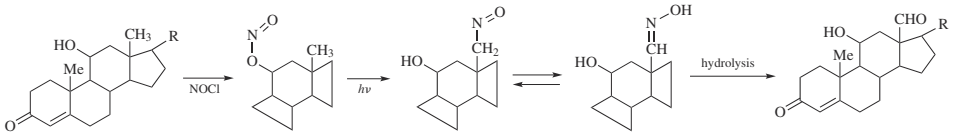
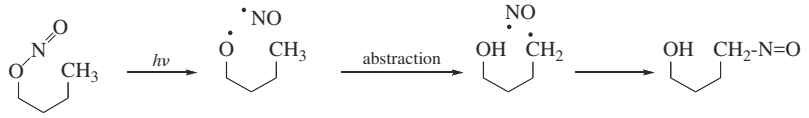
A common feature of the reactions in this section[923] is that they serve to introduce functionality at a position remote from functional groups already present. As such, they have proved very useful in synthesizing many compounds, especially in the steroid field (see also, Reactions **19-2** and **19-17**). When *N*-haloamines in which one alkyl group has a hydrogen in the 4 or 5 position are heated with sulfuric acid, pyrrolidines, or piperidines are formed, in a reaction known as the *Hofmann–Löffler reaction* (also called the *Hofmann–Löffler–Freytag reaction*).[924] The R′ group is normally alkyl, but the reaction has been extended to R′ = H by the use of concentrated sulfuric



acid solution and ferrous salts.[925] The first step of the reaction is a rearrangement, with the halogen migrating from the nitrogen to the 4 or 5 position of the alkyl group. It is possible to isolate the resulting haloamine salt, but usually this is not done, and the second step, the ring closure (Reaction **10-31**), takes place. The reaction is most often induced by heat, but this is not necessary, and irradiation and chemical initiators (e.g., peroxides) have been used instead. The mechanism is of a free radical type, with the main step involving an internal hydrogen abstraction.[926]

A similar reaction has been carried out on *N*-halo amides, which give γ-lactones[927]:



Another related reaction is the *Barton reaction*,[928] by which a methyl group in a unique position relative to an OH group can be oxidized to a CHO group. The alcohol is first converted to the nitrite ester. Photolysis of the nitrite results in conversion of the nitrite group to the OH group and nitrosation of the methyl group. Formation of a radical and with the methyl group in the appropriate position, hydrogen-atom transfer via a six-center transition state leads to a nitrite. Hydrolysis of the oxime tautomer gives the aldehyde, for example[929]

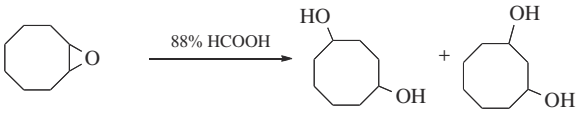
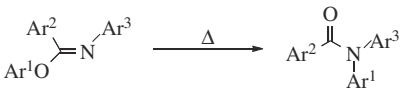
This reaction takes place only when the methyl group is in a favorable steric position.[930] The mechanism is similar to that of the *Hofmann–Löffler reaction*.[931]



This is one of the few known methods for effecting substitution at an angular methyl group. Not only CH_3 groups but also alkyl groups of the form RCH_2 and R_2CH can give the Barton reaction if the geometry of the system is favorable. An RCH_2 group is converted to the oxime R(C=NOH), which is hydrolyzable to a ketone, or to a nitroso dimer, while an R_2CH group gives a nitroso compound [$R_2C(NO)$]. With very few exceptions, the only carbons that become nitrosated are those in the position δ to the original OH group, indicating that a six-membered transition state is necessary for the hydrogen abstraction.[932]

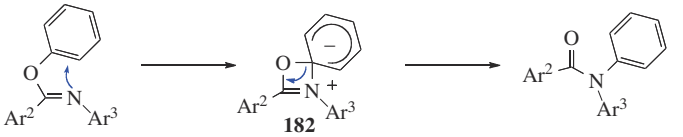
OS **III**, 159.

D. Noncyclic Rearrangements



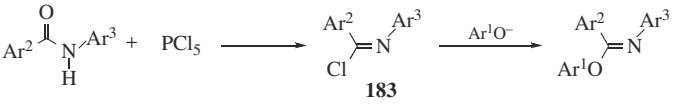
18-41 Hydride Shifts

The example shown is typical of a transannular hydride shift. The 1,2-diol is formed by a normal epoxide hydrolysis reaction (**10-7**).[933] For a discussion of 1,3 and longer hydride shifts, see Sec. 18.B.



18-42 The Chapman Rearrangement

1/*O*→3/ *N*-Aryl-migration



[930] See Burke, S.D.; Silks III, L.A.; Strickland, S.M.S. *Tetrahedron Lett.* ***1988****, 29*, 2761.
[931] See Green, M.M.; Boyle, B.A.; Vairamani, M.; Mukhopadhyay, T.; Saunders Jr., W.H.; Bowen, P.; Allinger, N.L. *J. Am. Chem. Soc.* ***1986****, 108,* 2381; Grossi, L. *Chemistry: European J.* ***2005****, 11*, 5419.
[932] See Nickon, A.; Ferguson, R.; Bosch, A.; Iwadare, T. *J. Am. Chem. Soc.* ***1977****, 99,* 4518.

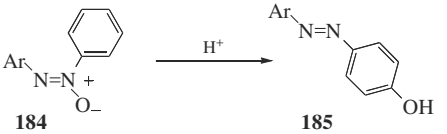
In the *Chapman rearrangement*, *N,N*-diaryl amides are formed when aryl imino esters are heated.[934] Best yields are obtained in refluxing tetraethylene glycol dimethyl ether (tetraglyme),[935] although the reaction can also be carried out without any solvent at all. Many groups may be present in the rings (e.g., alkyl, halo, OR, CN, and CO_2R). Aryl migrates best when it contains electron-withdrawing groups. On the other hand, electron-withdrawing groups in Ar^2 or Ar^3 decrease the reactivity. The products can be hydrolyzed to



diarylamines, and this is a method for preparing these compounds. The mechanism probably involves an intramolecular[936] aromatic nucleophilic substitution, resulting in a 1,3 oxygen-to-nitrogen shift via a species (e.g., **182**). Aryl imino esters can be prepared from *N*-aryl amides by reaction with PCl_5, followed by treatment

of the resulting imino chloride (**183**) with an aroxide ion.[937] Imino esters with any or all of the three groups being alkyl also rearrange, but they require catalysis by H_2SO_4 or a trace of methyl iodide or methyl sulfate.[938] The mechanism is different, involving an intermolecular process.[939] This is also true for derivatives for formamide ($Ar^2 = H$).

18-43 The Wallach Rearrangement

The conversion of azoxy compounds (e.g., **184**), upon acid treatment, to *p*-hydroxy azo compounds (e.g., **185**, or sometimes the *o*-hydroxy isomers[940]) is called the *Wallach rearrangement*.[941] When both para positions are occupied, the *o*-hydroxy product may be

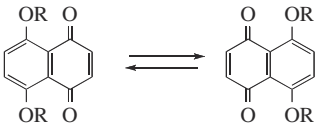
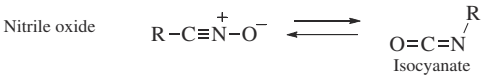
obtained, but ipso substitution at one of the para positions is also possible.[942] The following facts are known for the proposed mechanism[943]: (1) The para rearrangement is intermolecular.[944] (2) When the reaction was carried out with an azoxy compound in which the N—O nitrogen was labeled with ^{15}N, *both* nitrogens of the product carried the label equally,[945] demonstrating that the oxygen did not have a preference for migration to either the near or the far ring. This shows that there is a symmetrical intermediate. (3) Kinetic studies show that two protons are normally required for the reaction.[946] The following mechanism,[947] involving the symmetrical intermediate (**187**), has been proposed to explain the facts.[948] It has proved possible to obtain **186** and **187** as stable species in superacid solutions.[797] Another mechanism, involving an intermediate with only one positive charge, has been proposed for certain substrates at low acidities.[949]

A photochemical *Wallach rearrangement*[950] is also known: The product is the *o*-hydroxy azo compound, the OH group is found in the farther ring, and the rearrangement is intramolecular.[951]

18-44 Dyotropic Rearrangements



1/*C*-Trialkylsilyl,2/*O*-trialkylsilyl-interchange



A *dyotropic rearrangement*[952] is an uncatalyzed process in which two σ bonds simultaneously migrate intramolecularly.[953] There are two types. The above is an example of type 1, which consists of reactions in which the two σ bonds interchange positions.

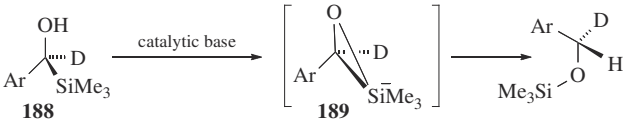
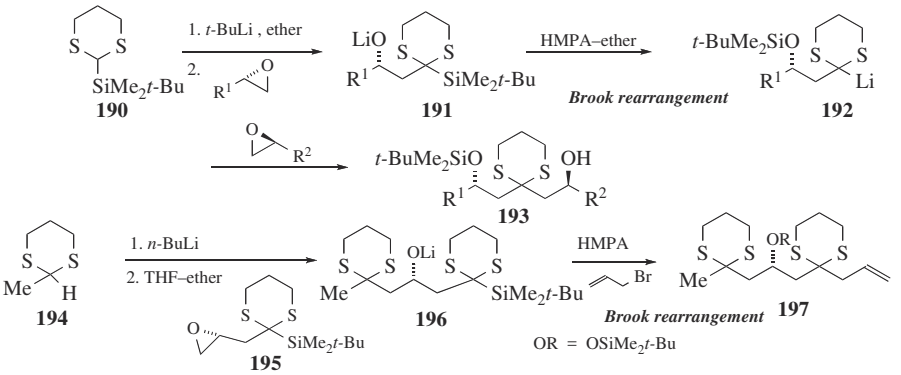
In type 2, the two σ bonds do not interchange positions. An example is



Some other examples are

Type 1  Ref. 954

Type 1  Ref. 955



Type 2  Ref. 956

A useful type 1 example is the *Brook rearrangement*,[957] a stereospecific intramolecular migration of silicon from carbon to oxygen that occurs for (α-hydroxybenzyl)trialkylsilanes (**188**) in the presence of a catalytic amount of base.[958] Formation of a Si—O bond rather than the Si—C bond drives the rearrangement, which is believed to proceed via formation of **189**, and does proceed with inversion of configuration at carbon and retention of configuration at silicon.[959] A *reverse Brook rearrangement* is also known.[960] The reaction has been extended to other systems. A *homo-Brook rearrangement* has also been reported.[961] Another variation is the *aza-Brook rearrangement* of α-(silylallyl)amines.[962] The *Brook rearrangement* has been used in synthesis involving silyl dithianes.[963] A *Brook rearrangement* mediated [6 + 2]-annulation has been used for the construction of eight-membered carbocycles.[964]

[964] Sawada, Y.; Sasaki, M.; Takeda, K. *Org. Lett.* ***2004****, 6*, 2277.

The *Brook rearrangement* has been used in two important synthetic applications, a multicomponent coupling protocol initiated by a *Brook rearrangement* involving silyl dithianes as mentioned, and anion relay chemistry (ARC) involving a *Brook rearrangement*. An example of the former is the conversion of the 2-silyl dithiane (**190**) to the anion with *tert*-butyllithium followed by ring opening of an epoxide to give **191**.[965] Treatment with HMPA triggers a solvent-controlled *Brook rearrangement* that gives a new dithiane anion (**192**), which then reacts with a different epoxide to give the final product **193**. An example of the anion relay chemistry treats dithiane (**194**) with *n*-butyllithium, and then **195** to give **196**.[966] Subsequent treatment with a variety of electrophiles (e.g., allyl bromide, in HMPA), leads to **197** via a *Brook rearrangement*, and then alkylation of the resultant dithiane anion. This reaction can be initiated by nucleophiles other than dithiane anion.

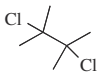
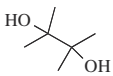
CHAPTER 19

Oxidations and Reductions





First, the terms oxidation and reduction must be clarified. Inorganic chemists define oxidation in two ways: loss of electrons and an increase in oxidation number. In organic chemistry, these definitions, while still technically correct, are not easy to apply. While electrons are directly transferred in some organic oxidations and reductions, and electrons are certainly transferred by making and breaking bonds, the mechanisms of most of these reactions do not involve a direct electron transfer. As for oxidation number, while this is easy to apply in some cases (e.g., the oxidation number of carbon in CH_4 is -4), in most cases attempts to apply the concept lead to fractional values or to apparent absurdities. Thus carbon in propane has an oxidation number of -2.67 and in butane of -2.5, although organic chemists seldom think of these two compounds as being in different oxidation states. An improvement could be made by assigning different oxidation states to different carbon atoms in a molecule, depending on what is bonded to them (e.g., the two carbons in acetic acid are obviously in different oxidation states), but for this a whole set of arbitrary assumptions would be required, since the oxidation number of an atom in a molecule is assigned on the basis of the oxidation numbers of the atoms attached to it. There would seem little to be gained by such a procedure. The practice in organic chemistry has been to set up a series of functional groups, in a qualitative way, arranged in order of increasing oxidation state, and then to define oxidation as *the conversion of a functional group in a molecule from one category to a higher one*. Reduction is the opposite. For the simple functional groups, this series is shown in Table 19.1.[1] Note that this classification applies only to a single carbon atom or to two adjacent carbon atoms. Thus 1,3-dichloropropane is in the same oxidation state as chloromethane, but 1,2-dichloropropane is in a higher one. Obviously, such distinctions are somewhat arbitrary, and if we attempt to carry them too far, we will find ourselves painted into a corner. Nevertheless, the basic idea has served organic chemistry well. Note that conversion of any compound to another in the same category is not an oxidation or a reduction. Most oxidations in organic chemistry involve a gain of oxygen and/or a loss of hydrogen (Lavoisier's original definition of oxidation). The reverse is true for reductions.

Of course, there is no oxidation without a concurrent reduction. However, reactions are classified as oxidations or reductions depending on whether the *organic compound* is oxidized or reduced. In some cases, both the oxidant and reductant are organic; those reactions are treated separately at the end of the chapter.

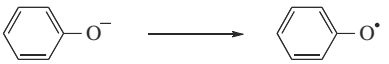
Approximate Oxidation Number				
−4	−2	0	+2	+4

[a]Oxidation is the conversion of a functional group in a molecule to a higher category; reduction is conversion to a lower one. Conversions within a category are neither oxidations nor reductions. The numbers given at the bottom are only approximations.



19.A. MECHANISMS

Note that our definition of oxidation has nothing to do with mechanism. Thus the conversion of bromomethane to methanol with KOH (Reaction **10-1**) and to methane with $LiAlH_4$ (Reaction **19-53**) have the same S_N2 mechanisms, but one is a reduction (according to our definition) and the other is not. It is impractical to consider the mechanisms of oxidation and reduction reactions in broad categories in this chapter as done for the reactions considered in Chapters 10–18.[2] The main reason is that the mechanisms are too diverse, and this in turn is because the bond changes are too different. For example, in Chapter 15, most reactions involved the bond change C=C → W—C—C—Y yet a relatively few mechanisms covered those reactions. But for oxidations and reductions the bond changes are far more diverse. Another reason is that the mechanism of a given oxidation or reduction reaction can vary greatly with the oxidizing or reducing agent employed. Very often the mechanism has been studied intensively for only one or a few of many possible agents.

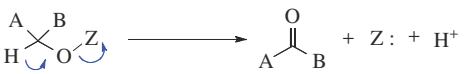
[2] See Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 16, Elsevier, NY, ***1980***; *Oxidation in Organic Chemistry,* Academic Press, NY, pt. A [Wiberg, K.B.], ***1965***, pts. B, C, and D [Trahanovsky, W.S.], ***1973, 1978, 1982***; Waters, W.A. *Mechanisms of Oxidation of Organic Compounds*, Wiley, NY, ***1964***; Stewart, R. *Oxidation Mechanisms*; W. A. Benjamin, NY, ***1964***. For a review, see Stewart, R. *Isot. Org. Chem.* ***1976****, 2,* 271.

Although oxidation and reduction mechanisms are not covered in the same way as other mechanisms, it is still possible to list a few broad mechanistic categories. The scheme of Wiberg is followed.[3]

1. *Direct Electron Transfer.*[4] Several reactions have been encountered in which the reduction is a direct gain of electrons or the oxidation is a direct loss of them. An example is the *Birch reduction* (Reaction **15-13**), where sodium directly transfers an electron to an aromatic ring. An example from this chapter is found in the bimolecular reduction of ketones with a metal (**19-76**), where again it is a metal that supplies the electrons. This kind of mechanism is found largely in three types of reaction:[5] (a) the oxidation or reduction of a free radical (oxidation to a positive or reduction to a negative ion), (b) the oxidation of a negative ion or the reduction of a positive ion to a comparatively stable free radical, and (c) electrolytic oxidations or reductions (an example is the *Kolbe reaction*, **14-29**). An important example of (b) is oxidation of phenolate ions:

These reactions occur easily because of the relative stability of the radicals involved.[6] The (SET) mechanism, which has been seen several times (see Sec. 10.B) is an important case.

2. *Hydride Transfer.*[7] In some reactions, a hydride ion is transferred to or from the substrate. The reduction of epoxides with $LiAlH_4$ is an example (**19-35**). Another is the *Cannizzaro reaction* (**19-81**). Reactions in which a hydride ion is transferred to a carbocation belong in this category:[8]

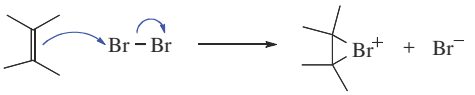


$$R^+ + R'H \longrightarrow RH + R'^+$$

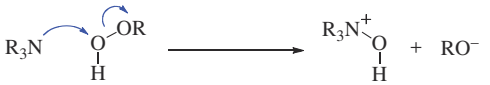
3. *Hydrogen-Atom Transfer.* Many oxidation and reduction reactions are free radical substitutions and involve the transfer of a hydrogen atom. For example, one of the two main propagation steps of Reaction **14-1** involves abstraction of hydrogen:

$$RH + Cl\bullet \longrightarrow R\bullet + HCl$$

This is the case for many of the reactions of Chapter 14.



4. *Formation of Ester Intermediates.* A number of oxidations involve the formation of an ester intermediate (usually of an inorganic acid), and then the cleavage of this intermediate:



[3] Wiberg, K.B. *Surv. Prog. Chem.* ***1963***, *1*, 211.
[4] See Eberson, L. *Electron Transfer Reactions in Organic Chemistry*; Springer, NY, ***1987***; Eberson, L. *Adv. Phys. Org. Chem.* ***1982***, *18,* 79; Deuchert, K.; Hünig, S. *Angew. Chem. Int. Ed.* ***1978***, *17*, 875.

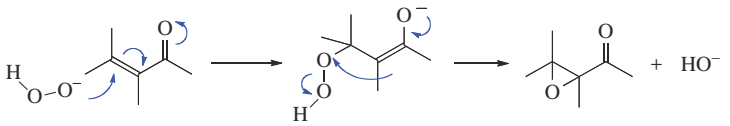
[6] See Mihailovic, M.Lj.; Cekovic, Z. in Patai, S. *The Chemistry of the Hydroxyl Group*, pt. 1, Wiley, NY, ***1971***, pp. 505–592.
[7] For a review, see Watt, C.I.F. *Adv. Phys. Org. Chem.* ***1988***, *24,* 57.
[8] See Nenitzescu, C.D. in Olah, G.A.; Schleyer, P.v.R. *Carbonium Ions*, Vol. 2, Wiley, NY, ***1970***, pp. 463–520.

Z is usually CrO_3H, MnO_3, or a similar inorganic acid moiety. One example of this mechanism will be seen in Reaction **19-23**, where A was an alkyl or aryl group, B was OH, and Z was CrO_3H. Another is the oxidation of a secondary alcohol to a ketone (Reaction **19-3**), where A and B are alkyl or aryl groups and Z is also CrO_3H. In the lead tetraacetate oxidation of glycols (Reaction **19-7**), the mechanism also follows this pattern, but the positive leaving group is carbon instead of hydrogen. Note that the cleavage shown is an example of an E2 elimination.



5. *Displacement Mechanisms.* In these reactions, the organic substrate uses its electrons to cause displacement on an electrophilic oxidizing agent. One example is the addition of bromine to an alkene (Reaction **15-39**).

An example from this chapter is found in Reaction **19-29**:

6. *Addition–Elimination Mechanisms.* In the reaction between α,β-unsaturated ketones and alkaline peroxide (**15-50**), the oxidizing agent adds to the substrate and then part of it is lost:

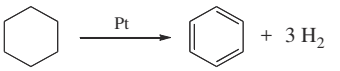
In this case, the oxygen of the oxidizing agent is in oxidation state −1 and the hydroxide ion departs with its oxygen in the −2 state, so it is reduced and the substrate is oxidized. There are several reactions that follow this pattern of addition of an oxidizing agent and the loss of part of the agent, usually in a different oxidation state. Another example is the oxidation of ketones with SeO_2 (Reaction **19-17**). This reaction is also an example of category 4, since it involves formation and E2 cleavage of an ester. This example shows that these six categories are not mutually exclusive.

19.B. REACTIONS

In this chapter, the reactions are classified by the type of bond change occurring to the organic substrate, in conformity with other chapters.[9] This means that there is no discussion in any one place of the use of a particular oxidizing or reducing agent (e.g., acid dichromate or $LiAlH_4$; except for a discussion of selectivity of reducing agents Sec. 19.B.ii, A). Some oxidizing or reducing agents are fairly specific in their action,

[9] See Hudlicky, M. *J. Chem. Educ.* ***1977****, 54*, 100.

attacking only one or a few types of substrate. Others, like acid dichromate, permanganate, $LiAlH_4$, and catalytic hydrogenation, are much more versatile.[10,11]



19.B.i. Oxidations[11]

In some cases, oxidations have been placed in another chapter. The oxidations of an alkene to a diol (Reaction **15-48**), and an aromatic compound to a diol (Reaction **15-49**), or oxidations to an epoxide (Reaction **15-50**) are placed in Chapter 15, for consistency with the concept of addition to a π bond. Diamination of an alkene (Reaction **15-53**) and formation of aziridines (Reaction **15-54**) are in Chapter 15 for the same reason. Most other oxidations have been placed here. The reactions in this section are classified into groups depending on the type of bond change involved. These groups are Section (A) eliminations of hydrogen, Section (B) oxidations involving cleavage of carbon–carbon bonds, Section (C) reactions involving replacement of hydrogen by oxygen, Section (D) reactions in which oxygen is added to the substrate, and Section (E) oxidative coupling.

A. Eliminations of Hydrogen

19-1 Aromatization of Six-Membered Rings

Hexahydro-terelimination

[11] For books on oxidation reactions, see Hudlicky, M. *Oxidations in Organic Chemistry,* American Chemical Society, Washington, ***1990***; Haines, A.H. *Methods for the Oxidation of Organic Compounds*, 2 vols., Academic Press, NY, ***1985, 1988*** [The first volume pertains to hydrocarbon substrates; the second mostly to oxygen- and nitrogen-containing substrates]; Chinn, L.J. *Selection of Oxidants in Synthesis*, Marcel Dekker, NY, ***1971***; Augustine, R.L.; Trecker, D.J. *Oxidation*, 2 Vols., Marcel Dekker, NY, ***1969, 1971***.

Six-membered alicyclic rings can be aromatized in a number of ways.[12] Aromatization is accomplished most easily if there are already one or two double bonds in the ring or if the ring is fused to an aromatic ring. The reaction can also be applied to heterocyclic five- and six-membered rings. Many groups may be present on the ring without interference, and even *gem*-dialkyl substitution does not always prevent the reaction: In such cases, one alkyl group often migrates or is eliminated, but more drastic conditions are usually required for this. In some cases, OH and COOH groups are lost from the ring. Cyclic ketones are converted to phenols. Seven-membered and larger rings are often isomerized to six-membered aromatic rings, although this is not the case for partially hydrogenated azulene systems, which are frequently found in nature; these are converted to azulenes.

There are three types of reagents most frequently used to effect aromatization.

1. Hydrogenation catalysts[13] (e.g., Pt, Pd,[14] and Ni). Palladium trifluoroacetate also facilitates oxidative aromatization of cyclohexene.[15] In this case, the reaction is the reverse of double-bond hydrogenation (**15-11** and **15-15**), and presumably the mechanism is also the reverse, although not much is known.[16] Cyclohexene has been detected as an intermediate in the conversion of cyclohexane to benzene, using Pt.[17] The substrate is heated with the catalyst at ~300–350 °C. The reactions can often be carried out under milder conditions if a hydrogen acceptor (e.g., maleic acid, cyclohexene, or benzene) is present to remove hydrogen as it is formed. The acceptor is reduced to the saturated compound. Other transition metals can be used.[18] It has been reported that dehydrogenation of 1-methylcyclohexene-1-^{13}C over an alumina catalyst gave toluene with the label partially scrambled throughout the aromatic ring.[19] For polycyclic systems, heating with oxygen on activated carbon generates the aromatic compound, as in the conversion of dihydroanthracene to anthracene.[20]
2. The elements sulfur and selenium, which combine with the hydrogen evolved to give, respectively, H_2S and H_2Se. Little is known about this mechanism either.[21]

3. Quinones[22] become reduced to the corresponding hydroquinones. Two important quinones often used for aromatizations are chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone) and DDQ (2,3-dichloro-5,6-dicyano-1,4-benzoquinone).[23] The latter is more reactive and can be used in cases where the substrate is difficult to dehydrogenate. It is likely that the mechanism involves a transfer of hydride to the quinone oxygen, followed by the transfer of a proton to the phenolate ion.[24]

Other reagents[25] have been used for aromatization of six-membered rings, including atmospheric oxygen, MnO_2,[26] SeO_2, H_2SO_4, and a Ru catalyst.[27] The last-mentioned reagent also dehydrogenates cyclopentanes to cyclopentadienes. In some instances, the hydrogen is not released as H_2 or transferred to an external oxidizing agent, but instead serves to reduce another molecule of substrate. This is a disproportionation reaction and can be illustrated by the conversion of cyclohexene to cyclohexane and benzene.

Heteroatom rings, as found in quinoline derivatives, for example, can be generated from amino-ketones with [hydroxy(tosyloxy)iodo]benzene and perchloric acid[28] or with $NaHSO_4$—$Na_2Cr_2O_7$ on wet silica.[29] Dihydropyridines are converted to pyridines with $NaNO_2$–oxalic acid and wet silica,[30] $BaMnO_4$,[31] $FeCl_3$–acetic acid,[32] or SeO_2.[33] *Hantzsch 1,4-dihydropyridines* (see Reactions **15-14** and **16-17**) are aromatized by treatment with ferric perchlorate in acetic acid.[34] Cyclic imines are converted to pyridine derivatives with NCS and then excess sodium methoxide.[35] Enamines are aromatized with Sn or Sb compounds.[36]

19-2 Dehydrogenations Yielding Carbon–Carbon Double Bonds

Dihydro-elimination

1

Dehydrogenation of an aliphatic compound to give a double bond in a specific location is not usually a feasible process, although industrially mixtures of alkenes are obtained in this way from mixtures of alkanes (generally by heating with chromia–alumina catalysts). There are, however, some notable exceptions. Heating cyclooctane with an Ir catalyst leads to cyclooctene.[38] Treating alkenes that have an allylic hydrogen with $CrCl_2$ converts them to allenes.[39] It is not surprising, however, that most of the exceptions generally involve cases where the new double bond can be in conjugation with a double bond or with an unshared pair of electrons already present.[40] One example is the synthesis developed by Leonard and Musker,[41] in which tertiary amines give enamines (Reaction **10-69**) when treated with mercuric acetate[42] (see the example above). In this case, the initial product is the iminium ion (**1**) that loses a proton to give the enamine. Other transition metal catalysts convert amines to enamines, including Co compounds.[43] *Hünig's base* (diisopropylethylamine) was converted to the enamine *N,N*-diisopropyl-*N*-vinylamine by heating with an Ir catalyst.[44]

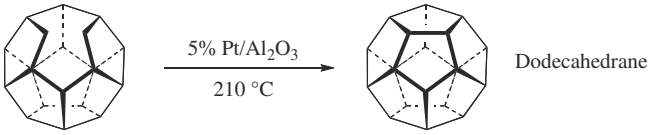
The oxidizing agent SeO_2 can in certain cases convert a carbonyl compound to an α,β-unsaturated carbonyl compound by removing H_2[45] (note that this reagent more often gives Reaction **19-17**). This reaction has been most often applied in the steroid series, an example being formation of **2** from **3**.[46] Similarly, SeO_2 has been used to dehydrogenate 1,4-diketones[47] and 1,2-diarylalkanes. These conversions can also be carried out by certain quinones, most notably DDQ (see Reaction **19-1**).[24] Molecular oxygen has been used to convert cyclic ketones to the conjugated ketone in the presence of a Pd catalyst.[48]

Simple aldehydes and ketones have been dehydrogenated (e.g., cyclopentanone → cyclopentenone) by $PdCl_2$,[49] by $FeCl_3$,[50] and by benzeneseleninic anhydride[51] (this reagent also dehydrogenates lactones in a similar manner), among other reagents. In an indirect method of achieving this conversion, the silyl enol ether of a simple ketone is treated with DDQ[52] or with triphenylmethyl cation[53] (for another indirect method, see Reaction **17-12**). Silyl enol ethers give the conjugated ketone upon treatment with ceric ammonium nitrate in DMF[54] or with $Pd(OAc)_2/NaOAc/O_2$.[55]

Simple linear alkanes have been converted to alkenes by treatment with certain transition metal compounds.[56]



4 **5**

An entirely different approach (remote functionalization) allows specific dehydrogenation, as reported by R. Breslow[57] and by J.E. Baldwin et al.[58] 3α-Cholestanol (**4**) was converted to 5α-cholest-14-en-3α-ol (**5**), for example, thus introducing a double bond at a specific site remote from any functional group.[59]

Certain 1,2-diarylalkenes (ArCH=CHAr′) have been converted to the corresponding alkynes (ArC≡CAr′) by treatment with *t*-BuOK in DMF.[60] Dihydroindoles are converted to indoles with *N*,*N*′,*N*″-trichloro-1,3,5-triazin-2,4,6-trione and DBU.[61]

A different kind of dehydrogenation was used in the final step of Paquette's synthesis of dodecahedrane[62]:

OS **V**, 428, **VII**, 4, 473.

19-3 Oxidation or Dehydrogenation of Alcohols to Aldehydes and Ketones

C,*O*-Dihydro-elimination

$$RCH_2OH \xrightarrow[\text{copper}]{\text{chromite}} RCHO \qquad RCHOHR' \xrightarrow[K_2Cr_2O_7]{H_2SO_4} RCOR'$$

Primary alcohols can be converted to aldehydes and secondary alcohols to ketones in seven main ways:[63]

1. *With Chromium Reagents.*[64] Secondary alcohols are easily oxidized to ketones by dichromate in acidic media[65] at room temperature or slightly above. A solution of chromic and sulfuric acid in water is known as the *Jones reagent*.[66] Secondary alcohols are oxidized to ketones rapidly and in high yield without disturbing any double or triple bonds that may be present (see Reaction **19-10**) and without epimerizing an adjacent stereogenic center.[67] Mixing sodium dichromate with an alcohol, without solvent, provides a method for oxidation when the mixture is shaken.[68] Chromium trioxide (CrO_3)[69] has been used to oxidize primary and alcohols under solvent-free conditions. Chromium trioxide on silica gel, in supercritical CO_2,

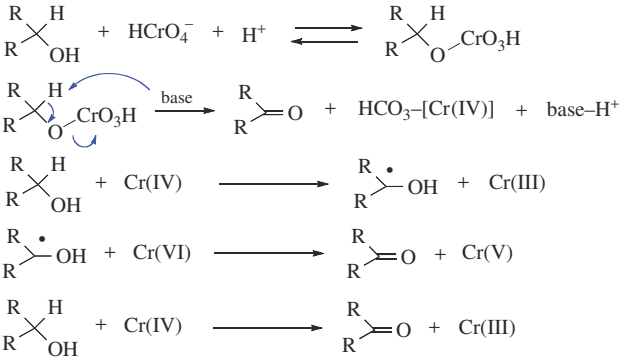
oxidizes alcohols to the corresponding carbonyl.[70] For acid-sensitive compounds, trimethylsilyl chromates[71] can be used. Chromium trioxide with aq *tert*-butylhydroperoxide oxidizes benzylic alcohols with microwave irradiation.[72] Phase-transfer catalysis is particularly useful,[73]especially when the substrates are generally insoluble in water (see Sec. 10.G.v). A catalytic amount of $Cr(acac)_3$ in conjunction with H_5IO_5 oxidizes benzylic alcohols to aldehydes.[74]



The Jones reagent can also oxidize primary allylic alcohols to the corresponding aldehydes,[75] although overoxidation to the carboxylic acid is a problem.[76] Oxidative cleavage of primary alcohols has been observed in the presence of molecular sieves 3 Å.[77] One way to mitigate overoxidation is to distil the aldehyde as it is formed, but this is not always possible. Due to these problems, other oxidizing conditions have been used to convert at least some primary alcohols to aldehydes.[78] Perhaps the three most commonly used Cr(VI) reagents used for the oxidation of allylic alcohols include[79] dipyridine Cr(VI) oxide (*Collins' reagent*),[80] pyridinium chlorochromate (PCC),[81] and pyridinium dichromate (PDC).[82] The PCC is somewhat acidic, and acid-catalyzed rearrangements have been observed.[83]

Analogous to the use of pyridine for PCC and PDC, a variety of amines and diamines have been converted to tetraalkylammonium halochromates or dichromates, including *N*-benzyl 1,4-diazabicyclo[2.2.2]octane ammonium dichromate with microwave irradiation,[84] γ-picolinium chlorochromate,[85] and quinolinium fluorochromate.[86] Benzyltriphenylphosphonium chlorochromate has been used in a similar manner.[87] Oxidizing agents have been supported on a polymer,[88]

including chromic acid,[89] as well as poly[vinyl(pyridinium fluorochromate)].[90] Triphenylmethylphosphonium dichromate is effective for selective oxidation of benzylic alcohols.[91]

Studies on the mechanism of oxidation with acid dichromate[92] led to the currently accepted mechanism as proposed by Westheimer[93] (cf. the first two steps with Sec. 19.A, category 4).

The base in the second step may be water, although it is also possible[94] that in some cases no external base is involved and that the proton is transferred directly to one of the CrO_3H oxygen atoms in which case the Cr(IV) species produced would be H_2CrO_3. Part of the evidence for this mechanism was the isotope effect of ~6 found on use of MeCDOHMe, showing that the α hydrogen is removed in the rate-determining step.[95] Note that, as in Reaction **19-23** the substrate is oxidized by three different oxidation states of chromium.[96]

With other oxidizing agents discussed below, mechanisms are less clear.[97] It seems certain that some oxidizing agents operate by a hydride-shift mechanism,[98] for example, dehydrogenation with triphenylmethyl cation[99] and the *Oppenauer oxidation*, and some by a free radical mechanism (e.g., oxidation with $S_3O_8^{2-}$[100] and with VO_2^{+}[101]). A summary of many proposed mechanisms is given by Littler.[102]

2. *With Manganese and Other Metal Oxidizing Agents*. Potassium permanganate ($KMnO_4$) has been used for the oxidation of alcohols.[103] Benzylic and allylic alcohols have been selectively oxidized to the aldehydes in the presence of saturated alcohols by the use of potassium permanganate ($KMnO_4$) under phase-transfer conditions.[104] Phase-transfer catalysis has also been used with chromic acid,[105] and ruthenium tetroxide.[106] Ultrasound has been used for $KMnO_4$ oxidations.[107] Permanganate supported on a polymer has been used.[108]

   Permanganate[109] is an important reagent for the selective oxidation of benzylic alcohols primary and benzylic alcohols, in preference to aliphatic substrates. [110]A variation oxidizes alcohols with $MnO_2/AlCl_3$.[111]

   An alternative to MnO_2 is the oxidation of allylic and benzylic alcohols with Me_3NO in the presence of $CHDFe(CO)_3$.[112] Similar oxidation occurs with $NaBrO_3$ in aq MeCN[113] or K_2FeO_4 on clay.[114] The reaction of AuCl with an anionic ligand leads to oxidation of primary alcohols to aldehydes.[115] The *Grubbs' catalyst,* $PhCH{=}Ru(PCy_3)_2Cl_2$, where Cy = cyclohetyl, (see **156** in Reaction **18-37**), in the presence of KOH, oxidized alcohols.[116]

Tetrapropylammonium perruthenate (Pr_4N^+ RuO_4^-; also called TPAP; the *Ley reagent*)[117] is an important oxidizing agent that is compatible with the presence of other functionality in the molecule.[118] In the presence of molecular oxygen, oxidation of alcohols is catalytic in TPAP.[119] This reagent has been bound to a polymer.[120] Methods have been developed for recovery of the catalyst and reuse of TPAP.[121]

Many other oxidizing agents have been employed. Examples include ruthenium tetroxide,[122] $MeReO_3$,[123] HNO_3 with a $Yb(OTf)_3$ catalyst,[124] $FeBr_3$—H_2O_2,[125] ceric ammonium nitrate in an ionic liquid,[126] a Bi catalyst,[127] O_2 with transition metal catalysts,[128] and with RuO_2 and a zeolite catalyst.[129] Microwave induced oxidation of benzylic alcohols was reported using zeolite-supported ferric nitrate.[130]

Reagents that can be used specifically to oxidize a secondary OH group in the presence of a primary OH group[131] are H_2O_2–ammonium molybdate,[132] or urea–H_2O_2 with $MgBr_2$,[133] while $RuCl_2(PPh_3)_3$–benzene,[134] osmium tetroxide,[135] and

Br_2—$Ni(OBz)_2$[136] all oxidize primary OH groups in the presence of a secondary OH group.[137] Certain zirconocene complexes can selectively oxidize only one OH group of a diol, even if both are primary.[138] α-Hydroxy ketones are oxidized to 1,2-diketones with $Bi(NO_3)_3$ and a $Cu(OAc)_2$ catalyst,[139] ferric chloride (solid state),[140] or O_2 and a V catalyst.[141] 1,2-Diols are oxidized to chiral α-hydroxy-ketones using NBS with a chiral Cu catalyst.[142]

3. *The Oppenauer Oxidation*. When a ketone in the presence of an aluminum alkoxide is used as the oxidizing agent (it is reduced to a secondary alcohol), the reaction is known as the *Oppenauer oxidation*.[143] This is the reverse of the *Meerwein–Ponndorf–Verley reaction* (**19-36**) and the mechanism is also the reverse. The ketones most commonly used are acetone, butanone, and cyclohexanone. A common base is aluminum *tert*-butoxide. The chief advantage of the method is its high selectivity. Although the method is most often used for the preparation of ketones, it has also been used for aldehydes. An Ir catalyst[144] has been developed for the *Oppenauer oxidation*, and also a water-soluble Ir catalyst.[145] Homogeneous water-soluble complexes catalyze the reaction.[146] An uncatalyzed reaction under supercritical conditions was reported.[147]
4. *DMSO Based Reagents*. The use of oxalyl chloride and DMSO at low temperature is called the *Swern oxidation*[148] and is widely used. A sulfonium salt is produced *in situ*, which reacts with the alcohol to generate the key intermediate required for oxidation.[149] Maintaining the low-reaction temperature is essential in this reaction, however, since the reagent generated *in situ* decomposes at temperatures significantly below ambient. Note that *Swern oxidation* of molecules having alcohol moieties, as well as a disulfide, leads to the ketone without oxidation of the sulfur.[150] Sulfoxides other than DMSO can be used in conjunction with oxalyl chloride for the oxidation of alcohols,[151] including fluorinated sulfoxides[152] and a polymer-bound sulfoxide.[153]

Similar oxidation of alcohols has been carried out with DMSO and other reagents[154] in place of DCC: acetic anhydride,[155] SO_3–pyridine–triethylamine,[156] trifluoroacetic anhydride,[157] pivaloyl chloride,[158] tosyl chloride,[159] $Ph_3P^+Br^-$,[160] trimethylamine *N*-oxide,[161] a Mo catalyst and O_2,[162] and methanesulfonic anhydride.[517] Dimethyl sulfoxide in 48% HBr oxidizes benzylic alcohols to aryl aldehydes.[163] An alcohol is treated with DMSO, DCC,[164] and anhydrous phosphoric acid[165] in what is called *Moffatt oxidation*. In this way, a primary alcohol can be converted to the aldehyde with no carboxylic acid being produced. The strong acid conditions are sometimes a problem, and complete removal of the dicyclohexylurea byproduct can be difficult.

5. *TEMPO and Related Reagents*. The nitroxyl radical TEMPO (**6**) has been used in conjunction with coreagents, including mcpba,[166] O_2 with transition metal catalysts,[167] O_2 with HBr and *tert*-butylnitrite,[168] $CuBr_2$(bpy)–air (bpy = 2,2′-bipyridyl),[169] $CuBr{\cdot}SMe_2$ in perfluorous solvents,[170] bromohydantoins,[171] enzymes,[172] carbenes,[173] $NaNO_2$—HCl,[174] $NaIO_4$,[175] and H_5IO_6.[176] Silica-supported TEMPO,[177] polymer-bound TEMPO,[178] and PEG–TEMPO[179] have been used. The TEMPO derived ionic liquids,[180] or ionic liquid-supported TEMPO[181] have

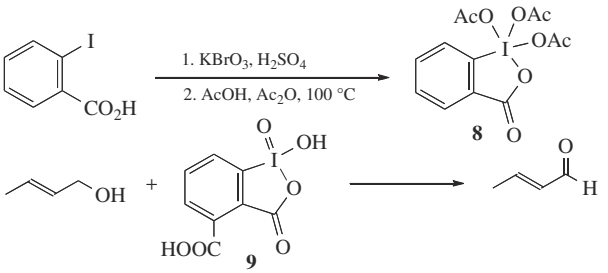
been used for the oxidation of alcohols. The TEMPO compound has also been used with a polymer-bound hypervalent iodine reagent.[182] A catalytic reaction using 5% TEMPO and 5% CuCl with O_2 in an ionic liquid oxidizes benzylic alcohols to the corresponding aldehyde.[183] Ion-supported TEMPO oxidation in water is possible.[184]



Other nitroxyl radical oxidizing agents are known.[185] A related oxidizing agent is oxoammonium salt **7** (*Bobbitt's reagent*), a stable and nonhygroscopic salt that oxidizes primary and secondary alcohols in dichloromethane.[186] The mechanism of oxidation for **7** has been examined.[187]

6 **7**

6. *With Hypervalent Iodine Reagents.*[188] Treatment of 2-iodobenzoic acid with $KBrO_3$ in H_2SO_4 and heating the resulting product to 100 °C with acetic anhydride and acetic acid[189] gives hypervalent iodine reagent (**8**), the so-called *Dess–Martin Periodinane*.[190] This reagent reacts with alcohols at ambient temperature to give the corresponding aldehyde or ketone.[191] The reaction is accelerated by water[192] and a water-soluble periodinane [*o*-iodoxybenzoic acid (**9**), IBX][193] has been prepared that oxidized allylic alcohols to conjugated aldehydes.[194] 2-Methyl-2-propanol has been used as a solvent.[195] The reagent has an indefinite shelf-life in a sealed container, but hydrolysis occurs upon long-term exposure to atmospheric moisture. A note of CAUTION! The *Dess–Martin reagent* can be shock sensitive under some conditions and explode ~200 °C.[196]

Iodine has been used as a cocatalyst.[197] Other hypervalent iodine oxidizing reagents are known,[198] including $PhI(OAc)_2$/TEMPO,[199] $PhI(OAc)_2$–chromium salen,[200] $PhI(OAc)_2$ supported on alumina with microwave irradiation,[201] and an ion-supported hypervalent iodine(III) reagent.[202] Microwave irradiation of benzylic alcohols with PhI(OH)OTs gave the corresponding aldehyde.[203] Hypervalent iodine compounds have been used in ionic liquids.[204] Heating benzylic alcohols with *o*-iodoxybenzoic acid under solvent-free conditions gave the aldehyde.[205] 2-Iodobenzenesulfonic acid is a very active catalyst for oxidation of alcohols using Oxone.[206]

7. *By Catalytic Dehydrogenation.* For the conversion of primary alcohols to aldehydes, dehydrogenation catalysts have the advantage over strong oxidizing agents that further oxidation to the carboxylic acid is prevented. Copper chromite is often used, but other catalysts (e.g., Ag and Cu), have also been employed. Many ketones were prepared in this manner. Catalytic dehydrogenation is more often used industrially than as a laboratory method. However, procedures using Cu(II) complexes,[207] Rh complexes,[208] Ru complexes,[209] Raney nickel,[210] and Pd complexes[211] (under phase transfer conditions)[212] have been reported. Allylic alcohols[213] are oxidized to the corresponding saturated aldehyde or ketone by heating with a Rh catalyst, and benzylic alcohols are converted to the aldehyde with a Rh

catalyst.[214] Propargylic alcohols are oxidized by heating with a V catalyst.[215] Secondary alcohols are oxidized with $Bi(NO_3)_3$ on Montmorillonite.[216] Biooxidation is possible as well via hydrogen transfer.[217]

8. *Miscellaneous Reagents.*[218] Nitric acid in dichloromethane oxidizes benzylic alcohols to the corresponding ketone.[219] Bromine is an effective oxidant, and iodine under photochemical conditions has been used.[220] Heating a 1,2-diol with NBS in CCl_4 gave the 1,2-diketone.[221] Iodine has been used in conjunction with DMSO and hydrazine.[222] Enzymatic oxidations have been reported.[223] Oxidation of alcohols in water is possible using I_2O_5.[224] Dimethyl dioxirane[225] oxidizes benzylic alcohols to the corresponding aldehyde,[226] and dioxirane reagents are sufficiently mild that an α,β-epoxy alcohol was oxidized to the corresponding ketone, without disturbing the epoxide, using methyl trifluoromethyl dioxirane.[227] Hydrogen peroxide with urea oxidizes aryl aldehydes in formic acid.[228] *tert*-Butylhydroperoxide with a Cu catalyst gives oxidation in an ionic liquid.[229] Potassium monoperoxysulfate in the presence of a chiral ketone oxidizes 1,2-diols to α-hydroxy ketones enantioselectively.[230] Potassium monoperoxysulfate also oxidizes secondary alcohols in the presence of O_2.[231] Air, in the presence of a zeolite oxidizes benzylic alcohols.[232] Periodic acid oxidizes aldehydes or ketones in the presence of a PCC catalyst.[233] Sodium hypochlorite in acetic acid[234] or in water with β-cyclodextrin[235] is a useful oxidizing agent. Calcium hypochlorite on moist alumina with microwave

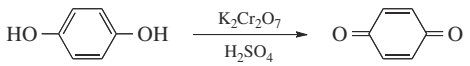
irradiation has been used to oxidize benzylic alcohols.[236] Hydrogen bromide in aq H_2O_2 oxidizes secondary alcohols to ketones.[237] With ultrasound, DDQ selectively oxidizes a benzylic or allylic hydroxyl group of 1,2-diols with those substituents.[238] Photoxidation of alcohols is possible in the presence of a catalytic amount of NBS.[239] A mixture of I_2—KI—K_2CO_3—H_2O oxidizes alcohols to aldehydes or ketones under anaerobic conditions.[240] Similarly $KBrO_3/ZrClO_2 \cdot 8H_2O$ can be used to oxidize alcohols.[241] Oxone oxidizes alcohols, catalyzed by $AlCl_3$.[242]



Tetrabutylammonium periodate[243] and benzyltriphenylphosphonium periodate.[244] oxidizes primary alcohols to aldehydes. On the other hand, *Fremy's salt* (see Reaction **19-4**) selectively oxidizes benzylic alcohols and not allylic or saturated ones.[245]

In a related reaction to the oxidation of alcohols, it is possible to oxidize ethers to aldehydes. Oxidation of trimethylsilyl ethers with O_2, a catalytic amount of *N*-hydroxyphthalimide and a Co catalyst, give an aldehyde.[246] Microwave irradiation with $BiCl_2$ oxidizes benzylic TMS ethers to the aldehyde.[247] Microwave irradiation on zeolite supported ferric nitrate has been used.[248] *O*-Tetrahydropyranyl ethers (*O*-THP) have been oxidized to the aldehyde with ferric nitrate on zeolites,[249] and the Pd catalyzed oxidation of allylic esters to conjugated ketones is known.[250] *N*-Bromosuccinimide with β-cyclodextrin oxidizes tetrahydropyranyl ethers in water.[251]

Ortho and para diols are easily oxidized to o- and *p*-quinones, respectively.[252] Either or both OH groups can be replaced by NH_2 groups to give the same products, although for the preparation of o-quinones only OH groups are normally satisfactory. The reaction has been successfully carried out with other groups para to OH or NH_2; halogen, OR, Me, *t*-Bu, and even H, although yields are poor with the latter. Many oxidizing agents have been used: acid dichromate,[253] silver oxide, silver carbonate, lead tetraacetate, HIO_4, $NBS—H_2O—H_2SO_4$,[254] dimethyl dioxirane,[255] and atmospheric oxygen.[256] Oxidation has been done photochemically with O_2 and tetraphenylporphine.[257] A particularly effective reagent for rings with only one OH or NH_2 group is $(KSO_3)_2N—O^{\bullet}$ (dipotassium nitrosodisulfonate; *Fremy's salt*), which is a stable free radical.[258] A mixture of 4-iodophenoxyacetic acid and Oxone is an effective catalyst for the oxidation of *p*-alkoxyphenols to *p*-quinones.[259] A supported iron phthalocyanine facilitates the aromatic oxidation of phenols.[260]

Less is known about the mechanism than is the case for oxidizing simple alcohols in Reaction **19-3**, and it seems to vary with the oxidizing agent. For oxidation of catechol with $NaIO_4$, it was found that the reaction conducted in $H_2{}^{18}O$ gave unlabeled quinone.[261] Therefore the following mechanism[262] was proposed:

When catechol was oxidized with MnO_4^- under aprotic conditions, a semiquinone radical ion intermediate was involved.[263] For autoxidations[264] (i.e., with atmospheric O_2) a free radical mechanism is known to operate.[265]

[264] For an example, see Rathore, R.; Bosch, E.; Kochi, J.K. *Tetrahedron Lett.* ***1994***, *35*, 1335.

[265] Sheldon, R.A.; Kochi, J.K. *Metal-Catalyzed Oxidations of Organic Compounds*, Academic Press, NY, ***1981***, pp. 368–381; Walling, C. *Free Radicals in Solution*, Wiley, NY, ***1957***, pp. 457–461.

Primary amines at a primary carbon can be dehydrogenated to nitriles. The reaction has been carried out with a variety of reagents, among others, I_2 in aq NH_3,[266] IBX see **19-3**, category 6),[267] NaOCl,[268] $Me_3N{-}O/OsO_4$,[269] $Ru/Al_2O_3/O2$,[270] and $CuCl/O_2$/pyridine.[271] Iodine and 1,3-diiodo-5,5-dimethylhydantoin in aq ammonia converted both amines and alcohols to nitriles.[272] Dehydrogenation of amines has been done in aq micelles.[273]

Several methods have been reported for the dehydrogenation of secondary amines to imines.[274] Among them[275] are treatment with (1) iodosylbenzene (PhIO) alone or in the presence of a Ru complex,[276] (2) DMSO and oxalyl chloride,[277] and (3) *t*-BuOOH and a Rh catalyst.[278] *N*-Tosyl aziridines are converted to *N*-tosyl imines when heated with a Pd catalyst.[279] An interesting variation treats pyrrolidine with iodobenzene and a Rh catalyst to give 2-phenylpyrroline.[280]

A reaction that involves dehydrogenation to an imine that then reacts further is the reaction of primary or secondary amines[281] with Pd black.[282] The imine initially formed by the dehydrogenation reacts with another molecule of the same or a different amine to give an aminal, which loses NH_3 or RNH_2 to give a secondary or tertiary amine. An example is the reaction between *N*-methylbenzylamine and butylmethylamine, which produces 95% *N*-methyl-*N*-butylbenzylamine.

In a related reaction, alkyl azides react with BrF_3 to give the corresponding nitrile.[283]

N,N′-Diarylhydrazines (hydrazo compounds) are oxidized to azo compounds by several oxidizing agents, including NaOBr, $K_3Fe(CN)_6$ under phase-transfer conditions[284] $FeCl_3$,[285] MnO_2 (this reagent yields cis azobenzenes),[286] $CuCl_2$, and air and NaOH.[287] The reaction is also applicable to *N,N′*-dialkyl- and *N,N′*-diacylhydrazines. Hydrazines (both alkyl and aryl) substituted on only one side also give azo compounds,[288] but these are unstable and decompose to nitrogen and the hydrocarbon:

$$\mathrm{Ar{-}NH{-}NH_2} \longrightarrow [\mathrm{Ar{-}N{=}NH}] \longrightarrow \mathrm{ArH} + \mathrm{N_2}$$

Aniline derivatives are converted to azo compounds by heating with cetyltrimethylammonium dichromate in chloroform.[289] When hydrazones are oxidized with HgO, Ag_2O, MnO_2, PbO_4, or certain other oxidizing agents, diazo compounds ($R_2C{=}N{-}NH_2 \rightarrow R_2C{=}N^+{=}N^-$) are obtained[290]:

Hydrazones of the form $ArCH{=}NNH_2$ react with HgO in solvents, (e.g., diglyme or ethanol) to give nitriles (ArCN).[291] It is possible to oxidize dimethylhydrazones ($R{-}C{=}N{-}NMe_2$) to the corresponding nitrile ($R{-}C{\equiv}N$) with magnesium monoperoxyphthalate (MMPP),[292] or with dimethyl dioxirane.[293] Oxone on wet alumina also converts hydrazones to nitriles with microwave irradiation.[294] Oximes of aromatic aldehydes are converted to aryl nitriles with $InCl_3$[295] (ketoximes give a *Beckmann rearrangement*, Reaction **18-17**).

In a related reaction, primary aromatic amines have been oxidized to azo compounds by a variety of oxidizing agents, among them MnO_2, lead tetraacetate, O_2 and a base, $BaMnO_4$,[296] and sodium perborate in acetic acid. *tert*-Butyl hydroperoxide has been used to oxidize certain primary amines to azoxy compounds.[297]

Nitrones [$C{=}N^+(R){-}O^-$] are generated by the oxidation of *N*-hydroxyl secondary amines with 5% aq NaOCl.[298] Secondary amines (e.g., dibenzylamine) can be converted to the corresponding nitrone by heating with cumyl hydroperoxide in the presence of a titanium catalyst.[299]

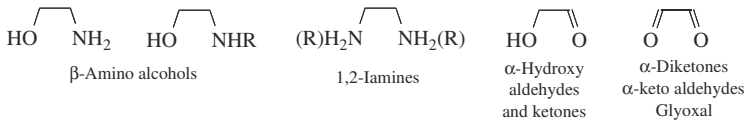
B. Oxidations Involving Cleavage of Carbon–Carbon Bonds[300]

19-7 Oxidative Cleavage of Glycols and Related Compounds



2/*O*-De-hydrogen-uncoupling

1,2-Diols (glycols) are easily cleaved under mild conditions and in good yield with periodic acid or lead tetraacetate.[301] The reaction generates 2 molar equivalents of aldehyde, or 2 molar equivalents of ketone, or 1 molar equivalent of each, depending on the groups attached to the two carbons. The yields are so good that alkenes are often converted to diols (Reaction **15-48**), and then cleaved with HIO_4 or $Pb(OAc)_4$ rather than being cleaved directly with ozone (Reaction **19-9**) or dichromate or permanganate (Reaction **19-10**). The diol can be generated and cleaved *in situ* from an alkene to give the carbonyl compounds.[302] A number of other oxidizing agents also give the same products, among them[303] aq sodium hypochlorite (NaOCl),[304] activated MnO_2,[305] O_2 and a Ru catalyst,[306] or PCC.[307] Permanganate, dichromate, and several other oxidizing agents[308] also cleave glycols, giving carboxylic acids rather than aldehydes, but these reagents are seldom used synthetically.

The two reagents (periodic acid and lead tetraacetate) are complementary, since periodic acid is best used in water and lead tetraacetate in organic solvents. Chiral lead carboxylates have been prepared for the oxidative cleavage of 1,2-diols.[309] When three or more OH groups are located on adjacent carbons, the middle one (or ones) is converted to formic acid.

Other compounds that contain oxygen atoms or nitrogen atoms on adjacent carbons undergo similar cleavage:

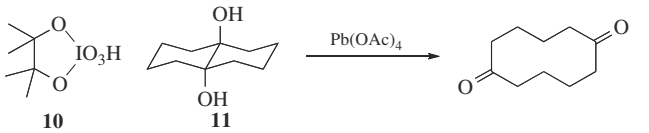
Cyclic 1,2-diamines are cleaved to diketones with dimethyl dioxirane.[310] α-Diketones and α-hydroxy ketones are also cleaved by alkaline H_2O_2.[311] Periodic acid (HIO_4) has been used to cleave epoxides to aldehydes,[312] for example,

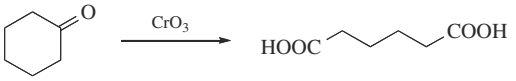


α-Hydroxy and α-keto acids are not cleaved by HIO_4 but are cleaved by $NaIO_4$ in methanol in the presence of a crown ether $Pb(OAc)_4$,[313] alkaline H_2O_2, and other reagents. These are oxidative decarboxylations. α-Hydroxy acids give aldehydes or ketones, and α-keto acids give carboxylic acids. Also see, Reaction **19-12** and **19-13**.

The mechanism of glycol oxidation with $Pb(OAc)_4$ was proposed by Criegee et al.:[314]

This mechanism is supported by (1) the kinetics are second order (first order in each reactant); (2) added acetic acid retards the reaction (drives the equilibrium to the left); and (3) *cis*-glycols react much more rapidly than *trans* glycols.[315] For periodic acid, the mechanism is similar, with the intermediate (**10**)[316]

10 **11**



However, the cyclic-intermediate mechanism cannot account for all glycol oxidations, since some glycols that cannot form such an ester (e.g., **11**) are nevertheless cleaved by lead tetraacetate (although other glycols that cannot form cyclic esters are *not* cleaved, by either reagent[317]). To account for cases like **11**, a cyclic transition state has been proposed:[315]

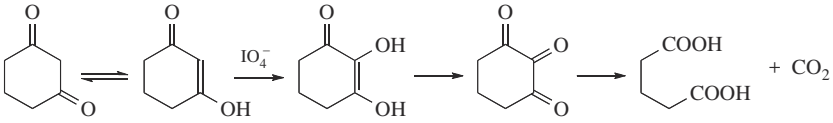
19-8 Oxidative Cleavage of Ketones, Aldehydes, and Alcohols

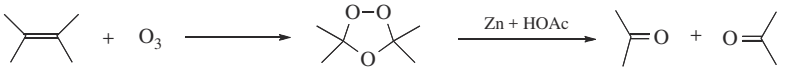


Cycloalkanone oxidative ring opening

Oxidative cleavage of open-chain ketones or alcohols[318] is a preparative procedure that is seldom useful, not because these compounds do not undergo oxidation (they do, except for diaryl ketones), but because the result is generally a hopeless mixture. Aryl methyl ketones (e.g., acetophenone), however, are readily oxidized to aryl carboxylic acids with Re_2O_7 and 70% aq *tert*-butyl hydroperoxide.[319] Oxygen with a mixture of Mn and Co catalysts give similar oxidative cleavage,[320] as do hypervalent iodine compounds.[321] Aldehydes, (e.g., $PhCH_2CHO$) are cleaved to benzaldehyde with phosphonium dichromate in refluxing acetonitrile.[322] 1,3-Diketones (e.g., 1,3-diphenyl-1,3-propanedione) are oxidatively cleaved with aq Oxone to give benzoic acid.[323] Cyclic α-chloro ketones are cleaved to give an α,ω-functionalized compound (acetal–ester) when treated with cerium (IV) sulfate tetrahydrate and O_2.[324]

Despite problems with acyclic ketones, the reaction is useful for the conversion of cyclic ketones and the corresponding secondary alcohols to the dicarboxylic acid in good yield. The formation of adipic acid from cyclohexanone (shown above) is an important industrial procedure. Dichromate in acidic media and permanganate are the most common oxidizing agents, although autoxidation (oxidation with atmospheric oxygen) in alkaline solution[325] and potassium superoxide under phase-transfer conditions[326] have also been used. *O*-Silyl-ketones have been cleaved to esters using electrolysis in alcohol solvents.[327]

Cyclic 1,3-diketones, which exist mainly in the mono-enolic form, can be cleaved with sodium periodate with loss of one carbon, for example,[328]



The species actually undergoing the cleavage is the triketone, so this is an example of Reaction **19-7**. Cyclic 1,3-diketones are converted to α,ω-diesters with an excess of $KHSO_5$ in methanol.[329]

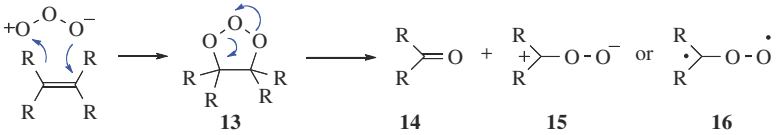
19-9 Ozonolysis

Oxo-uncoupling

12



When compounds containing double bonds are treated with ozone, usually at low temperatures, initial formation of a 1,2,3-trioxolane is followed by formation of compounds called 1,2,4-trioxolanes (*ozonides*, **12**). These compounds can be isolated but, because some of them are explosive, they are decomposed with Zn and acetic acid or catalytic hydrogenation. More commonly they are decomposed with DMS[330] to give 2 molar equivalents of aldehyde, or 2 molar equivalents of ketone, or 1 molar equivalent of each, depending on the groups attached to the alkene.[331] The decomposition of **12** has also been carried out with triethylamine[332] and with reducing agents (e.g., trimethyl phosphite[333] or thiourea).[334] However, ozonides can also be *oxidized* with oxygen, peroxyacids, or H_2O_2 to give ketones and/or carboxylic acids. Note that the presence of a hydrogen atom on the C=C unit (C=C—H) leads to differences in oxidation or reduction of **12**. In such a system, oxidation leads to the acid, whereas reduction leads to the aldehyde. Note that the presence of a hydrogen atom on the C=C unit (C=C—H) leads to differences in oxidation or reduction of **12**. In such a system, oxidation leads to the acid, whereas reduction leads to the aldehyde. It is also possible to reduce **12** with $LiAlH_4$, $NaBH_4$, BH_3, or catalytic hydrogenation with excess H_2 to give 2 molar equivalents of alcohol.[335] Ozonides can be treated with ammonia, hydrogen, and a catalyst to give the corresponding amines,[336] or with an alcohol and anhydrous HCl to give the corresponding carboxylic esters.[337] Ozonolysis is therefore an important synthetic reaction.[338]Ozonolysis can be done in solvent–water mixtures.[339]

Many alkenes undergo ozonolysis, including cyclic alkenes, where cleavage gives rise to one bifunctional product (an α,ω-difunctional molecule). Alkenes in which the double bond is connected to electron-donating groups react many times faster than those in which it is connected to electron-withdrawing groups.[340] Ozonolysis of compounds containing more than one double bond generally leads to cleavage of all the bonds. In some cases,

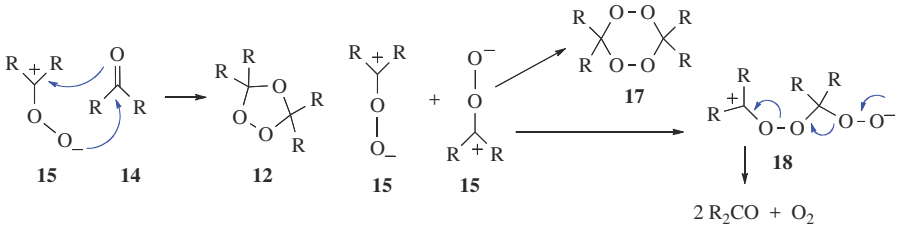
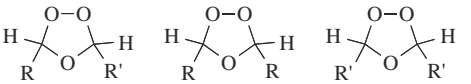
especially when bulky groups are present, conversion of the substrate to an epoxide (**15-50**) becomes an important side reaction and can be the main reaction.[341] Rearrangement is possible in some cases.[342] Ozonolysis of triple bonds[343] is less common and the reaction proceeds less easily, since ozone is an electrophilic agent[344] and prefers double to triple bonds (Sec. 15.B.i). Compounds that contain triple bonds generally give carboxylic acids, although sometimes ozone oxidizes them to α-diketones (Reaction **19-26**).



Aromatic compounds are attacked less readily than alkenes, but cleavage is known. Aromatic compounds behave as if the double bonds in the Kekulé structures were really there. Thus benzene gives 3 molar equivalents of glyoxal (HCOCHO), and *o*-xylene gives a glyoxal/MeCOCHO/MeCOCOMe ratio of 3 : 2 : 1, which shows that in this case cleavage is statistical. With polycyclic aromatic compounds the site of attack depends on the structure of the molecule and on the solvent.[345]



Although a large amount of work has been done on the mechanism of ozonization (formation of **12**), not all the details are known. Note that a primary ozonide has been trapped.[346] Criegee[347] formulated the basic mechanism. The first step of the *Criegee mechanism*[348] is a 1,3-dipolar addition (Reaction **15-58**) of ozone to the substrate to give the "initial" or "primary" ozonide, the structure of which has been shown to be the 1,2,3-trioxolane (**13**) by microwave and other spectral methods.[349] However, **13** is highly unstable and cleaves to an aldehyde or ketone (**14**) and an intermediate[350] that Criegee showed as a zwitterion (**15**), but which may be a diradical (**16**). This intermediate is usually referred to as a carbonyl oxide.[351] The carbonyl oxide, which will be represented as **15**, can then undergo various reactions, three of which lead to normal products. One is a recombination with **14**, which leads to ozonide **12**. The second is a dimerization to the bis(peroxide) **17**, and the third a kind of dimerization to **18**.[352] If the first path is taken (this

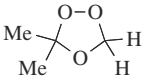
is normally possible only if **14** is an aldehyde; most ketones do not do this[353,354] the product is an ozonide (1,2,4-trioxolane, **12**),[355] and hydrolysis



of the ozonide gives the normal products. If **17** is formed, hydrolysis of it gives one of the products, and, of course, **14**, which then does not undergo further reaction, is the other. If intermediate **18** is formed, direct decomposition is possible, as shown, to give the normal products and oxygen. In protic solvents, **15** is converted to a hydroperoxide, and these have been isolated [e.g., $Me_2C(OMe)OOH$ from $Me_2C{=}CMe_2$ in methanol]. Further evidence for the mechanism is that **17** can be isolated in some cases (e.g., from $Me_2C{=}CMe_2$). But perhaps the most impressive evidence comes from the detection of cross-products. In the Criegee mechanism, the two parts of the original alkene break apart and then recombine to form the ozonide. In the case of an unsymmetrical alkene ($RCH{=}CHR'$) there should be three ozonides:

since there are two different aldehydes (**14**) and two different species (**15**). These compounds can recombine in the three ways shown. Actually *six* ozonides, corresponding to the cis and trans forms of these three, were isolated and characterized for methyl oleate.[356] Similar results have been reported for smaller alkenes (e.g., 2-pentene, 4-nonene, and even 2-methyl-2-pentene.[357] The last-mentioned case is especially interesting, since it is quite plausible that this compound would cleave in only one way, so that only one ozonide (in cis and trans versions) would be found; but this is not so, and three were found for this case too. However, terminal alkenes give little or no cross-ozonide formation.[358] In general, the less alkylated end of the alkene tends to go to **14** and the other to **15**. Still other evidence[359] for the Criegee mechanism is (1) When $Me_2C{=}CMe_2$ was ozonized in the presence of HCHO, the ozonide (**19**) could be isolated[354]; (2) **15** prepared in an entirely different manner

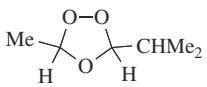
(photooxidation of diazo compounds), reacted with aldehydes to give ozonides[360]; and (3) *cis*-and *trans*-alkenes generally give the same ozonide, which would be expected if they cleave first.[361] However, this was not true for $Me_3CCH{=}CHCMe_3$, where the *cis*-alkene gave the *cis*-ozonide (chiefly), and the trans gave the trans.[362]



19

The latter result is not compatible with the Criegee mechanism. Also incompatible with the Criegee mechanism was the finding that the cis/trans ratios of symmetrical (cross) ozonides obtained from *cis*- and *trans*-4-methyl-2-pentene were not the same.[363] If the Criegee mechanism operated as shown above, the cis/trans ratio for each of the two cross ozonides would have to be identical for the cis- and *trans*-alkenes, since in this mechanism they are completely cleaved.

The above stereochemical results have been explained[364] on the basis of the Criegee mechanism with the following refinements: (1) The formation of **13** is stereospecific, as expected from a 1,3-dipolar cycloaddition. (2) Once formed, **15** and **14** remain attracted to each other, much like an ion pair. (3) Intermediate **15** exists in syn and anti forms, which are produced in different amounts and can hold their shapes, at least for a time. This is plausible if we remember that a C=O canonical form contributes to the structure of **19**. (4) The combination of **15** and **14** is also a 1,3-dipolar cycloaddition, so configuration is retained in this step too.[365]

Evidence that the basic Criegee mechanism operates even in these cases comes from ^{18}O labeling experiments, making use of the fact, mentioned above, that mixed ozonides (e.g., **15**) can be isolated when an external aldehyde is added. Both the normal and modified Criegee mechanisms predict that if ^{18}O-labeled aldehyde is added to the ozonolysis mixture, the label will appear in the ether oxygen (see the reaction between **15** and **14**), and this is what is found.[366] There is evidence that the *anti*-**15** couples much more readily than the *syn*-**15**.[367]

syn-**15** *anti*-**15** **20** **16** (R=H)

The ozonolysis of ethylene[368] in the liquid phase (without a solvent) was shown to take place by the Criegee mechanism.[369] This reaction has been used to study the structure of the intermediate **15** or **16**. The compound dioxirane (**20**) was identified in the reaction mixture[370] at low temperatures and is probably in equilibrium with the biradical **16** (R = H). Dioxirane has been produced in solution, but it oxidatively cleaves dialkyl ethers (e.g., Et—O—Et) via a chain-radical process,[371] so the choice of solvent is important.

Ozonolysis in the gas phase is not generally carried out in the laboratory. However, the reaction is important because it takes place in the atmosphere and contributes to air pollution.[372] There is much evidence that the Criegee mechanism operates in the gas phase too, although the products are more complex because of other reactions that also take place.[373]

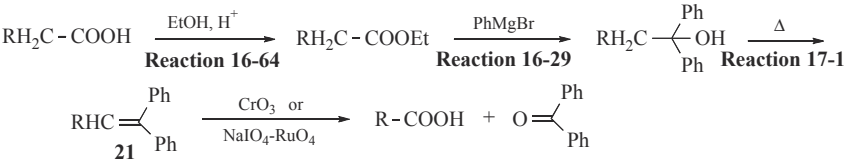
19-10 Oxidative Cleavage of Double Bonds and Aromatic Rings

Oxo-de-alkylidene-bisubstitution, and so on



$$R_2C{=}CHR \xrightarrow{CrO_3} R_2C{=}O + RCOOH$$

Carbon–carbon double bonds can be cleaved by many oxidizing agents,[374] the most common of which are permanganate in neutral or acid media and dichromate in acid media. The products are generally 2 molar equivalents of ketone, 2 molar equivalents of carboxylic acid, or 1 molar equivalent of each, depending on what groups are attached to the alkene. With ordinary solutions of permanganate or dichromate, yields are generally low and the reaction is seldom a useful synthetic method; but high yields can be obtained by oxidizing with $KMnO_4$ dissolved in benzene containing the crown ether dicyclohexano-18-crown-6 (see Sec. 3.C.ii).[375] The crown ether coordinates with K^+, permitting the $KMnO_4$ to dissolve in benzene. Another reagent frequently used for synthetic purposes is the *Lemieux-von Rudloff reagent*: HIO_4 containing a trace of MnO_4^-.[376] The MnO_4^- is the actual oxidizing agent, being reduced to the manganate stage, and the

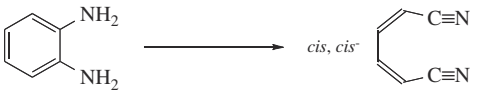
purpose of the HIO_4 is to reoxidize the manganate back to MnO_4^-. Another reagent that behaves similarly is $NaIO_4$–ruthenium tetroxide.[377] Oxidative cleavage of alkenes is catalyzed by Ru with $IO(OH)_5$.[378] Cyclic alkenes are cleaved to α,ω-diketones, keto-acids, or dicarboxylic acids. Cyclic alkenes are cleaved to dialdehydes with $KMnO_4{\cdot}CuSO_4$ in dichloromethane.[379] A combination of $RuCl_3/HIO_5$ oxidatively cleaves cyclic alkenes to dicarboxylic acids.[380]

The *Barbier–Wieland procedure* for decreasing the length of a chain by one carbon involves oxidative cleavage by acid dichromate ($NaIO_4$—RuO_4 has also been used), but this is cleavage of a 1,1-diphenyl alkene (**21**), which generally gives good yields. Addition of a catalytic amount of OsO_4 to *Jones reagent* (Reaction **19-3**) leads to good yields of the carboxylic acid from simple alkenes.[381] A combination of Oxone and OsO_4 in DMF cleaves alkenes to carboxylic acids.[382] Cleavage of alkynes is generally rather difficult, but treatment of internal alkynes with an excess of Oxone with a Ru catalyst leads to aliphatic carboxylic acids.[383]



With certain reagents, the oxidation of double bonds can be stopped at the aldehyde stage, and in these cases the products are the same as in the ozonolysis procedure. Among these reagents are *tert*-butyl iodoxybenzene,[384] $KMnO_4$ in THF—H_2O,[385] and $NaIO_4$—OsO_4.[386] Enol ethers, [$RC(OR')=CH_2$] have been cleaved to carboxylic esters [$RC(OR')=O$] by atmospheric oxygen.[387] Oxidative cleavage of alkenes is catalyzed by a Mn–porphyrin complex.[388]

The mechanism of oxidation probably involves in most cases the initial formation of a glycol (Reaction **15-29**) or cyclic ester,[389] and then further oxidation as in Reaction **19-7**.[390] In line with the electrophilic attack on the alkene, triple bonds are more resistant to oxidation than double bonds. Terminal triple-bond compounds can be cleaved to

carboxylic acids with $Tl(III)NO_3$[391] or with [bis(trifluoroacetoxy)iodo]pentafluorobenzene [i.e., $C_6F_5I(OCOCF_3)_2$].[392]

Aromatic rings can be cleaved with strong enough oxidizing agents. An important laboratory reagent for this purpose is RuO_4 along with a cooxidant (e.g., $NaIO_4$ or NaOCl and household bleach can be used). Ruthenium tetroxide is an expensive reagent, but the cost can be greatly reduced by the use of an inexpensive cooxidant (e.g., NaOCl), the function of which is to oxidize RuO_2 back to ruthenium tetroxide. Examples[393] are the oxidation of naphthalene to phthalic acid[394] and, even more remarkably, of cyclohexylbenzene to cyclohexanecarboxylic acid[395] (note the contrast with Reaction **19-11**). The latter conversion was also accomplished with ozone.[396] Another reagent that oxidizes aromatic rings is air catalyzed by V_2O_5. The oxidations of naphthalene to phthalic anhydride and of benzene to maleic anhydride by this reagent are important industrial procedures.[397] *o*-Diamines have been oxidized with nickel peroxide, with lead tetraacetate,[398] and with O_2 catalyzed by CuCl:[399]

The last-named reagent also cleaves *o*-dihydroxybenzenes (catechols) to give, in the presence of MeOH, the monomethylated dicarboxylic acids ($HO_2C—C=C—C=C—CO_2Me$).[400]

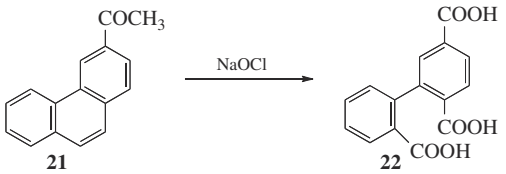
19-11 Oxidation of Aromatic Side Chains



Oxo,hydroxy-de-dihydro,methyl-tersubstitution

$$ArR \xrightarrow{KMnO_4} ArCOOH$$

Alkyl chains on aromatic rings can be oxidized to CO_2H groups by many oxidizing agents, including permanganate, nitric acid, and acid dichromate.[401] The method is most often applied to the methyl group ($CH_3 \rightarrow CO_2H$), although longer side chains can also be cleaved. Tertiary alkyl groups are resistant to oxidation, and when they *are* oxidized, ring cleavage usually occurs too.[402] It is usually difficult to oxidize an R group on a fused

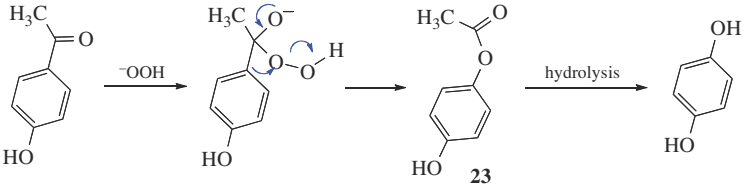
aromatic system without cleaving the ring or oxidizing it to a quinone (Reaction **19-19**). However, this has been done (e.g., 2-methylnaphthalene was converted to 2-naphthoic acid) with aq $Na_2Cr_2O_7$.[403] Aryl methyl groups are oxidized to aryl CO_2H with NaOCl in acetonitrile,[404] or with NBS in aqueous NaOH under photochemical conditions.[405] Functional groups can be present anywhere on the side chain and, if in the α position, greatly increase the ease of oxidation. An exception is an α phenyl group. In such cases, the reaction stops at the diaryl ketone stage. Molecules containing aryl groups on different carbons cleave so that each ring gets one carbon atom, as in the cleavage of the 9,10-bond of dihydrophenanthrenes (**21** to **22**).

21 **22**

It is possible to oxidize only one alkyl group of a ring that contains more than one. The order of reactivity[406] toward most reagents is $CH_2Ar > CHR_2 > CH_2R > CH_3$.[407] Groups on the ring susceptible to oxidation (OH, NHR, NH_2, etc.) must be protected. The oxidation can be performed with oxygen, in which case it is autoxidation, and the mechanism is like that in Reaction **14-7**, with a hydroperoxide intermediate.[408]With this procedure it is possible to isolate ketones from $ArCH_2R$, and this is often done.[409]



The mechanism has been studied for the following closely related reaction: $Ar_2CH_2 + CrO_3 \rightarrow Ar_2C{=}O$.[410] A deuterium isotope effect of 6.4 was found, indicating that the rate-determining step is either $Ar_2CH_2 \rightarrow Ar_2CH^{\bullet}$ or $Ar_2CH_2 \rightarrow Ar_2CH^{+}$. Either way this explains why tertiary groups are not converted to CO_2H and why the reactivity order is $CHR_2 > CH_2R > CH_3$, as mentioned above. Both free radicals and carbocations exhibit this order of stability (Chapter 5). The two possibilities are examples of categories 2 and 3 in Section 19.A. Just how the radical or the cation goes on to the product is not known.

When the alkyl group is one oxidizable to CO_2H (Reaction **19-11**), cupric salts are oxidizing agents, and the OH group is found in a position ortho to that occupied by the alkyl group.[411] This reaction is used industrially to convert toluene to phenol.

In another kind of reaction, an aromatic aldehyde (ArCHO) or ketone (ArCOR′) is converted to a phenol (ArOH) on treatment with alkaline H_2O_2,[412] but there must be an OH or NH_2 group in the ortho or para position. This is called the *Dakin reaction*.[413] The

mechanism may be similar to that of the *Baeyer–Villiger Reaction* (**18-19**).[414] The intermediate **23** has been isolated.[415] The reaction has been performed on aromatic aldehydes with an alkoxy group in the ring, and no OH or NH_2. In this case, acidic H_2O_2 was used.[416] The Dakin reaction has been done in ionic liquids.[417]

19-12 Oxidative Decarboxylation

Acetoxy-de-carboxy-substitution

Hydro-carboxyl-elimination

Carboxylic acids can be decarboxylated[418] with lead tetraacetate to give a variety of products: an ester (ROAc), the alkane (RH) (see Reaction **12-40**), an alkene if α,β hydrogen is present, as well as numerous other products arising from rearrangements, internal cyclizations,[419] and reactions with solvent molecules. When R is tertiary, the chief product is usually the alkene. High yields of alkenes can also be obtained when R is primary or secondary using $Cu(OAc)_2$ along with the $Pb(OAc)_4$.[420] In the absence of Cu $(OAc)_2$, primary acids give mostly alkanes (though yields are generally low) and secondary acids may give carboxylic esters or alkenes. Other oxidizing agents,[421] including Co(III), Ag(II), Mn(III), and Ce(IV), have also been used to effect oxidative decarboxylation.[422]

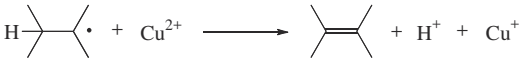
The mechanism with lead tetraacetate is generally accepted to be of the free radical type.[423] First, there is an interchange of ester groups:

$$Pb(OAc)_4 + RCOOH \longrightarrow \underset{\mathbf{24}}{Pb(OAc)_3OCOR} \quad \text{or} \quad \underset{\mathbf{25}}{Pb(OAc)_2(OCOR)_2}$$



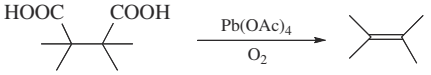
A free radical chain mechanism follows (shown for **24** although **25** and other lead esters can behave similarly)

$$\text{Initiation} \quad \underset{\mathbf{24}}{Pb(OAc)_3OCOR} \longrightarrow {\bullet}Pb(OAc)_3 + R{\bullet} + CO_2$$

$$R{\bullet} + Pb(OAc)_3OCOR \longrightarrow R^+ + {\bullet}Pb(OAc)_2OCOR + OAc^-$$

$$\text{Propagation} \quad {\bullet}Pb(OAc)_2OCOR \longrightarrow Pb(OAc)_2 + R{\bullet} + CO_2$$

Products can then be formed either from $R^{\bullet}$ or R^+. Primary $R^{\bullet}$ abstract H from solvent molecules to give RH. The R^+ ion can lose H^+ to give an alkene, react with HOAc to give the carboxylic ester, react with solvent molecules or with another functional group in the same molecule, or rearrange, thus accounting for the large number of possible products. The radical $R^{\bullet}$ can also dimerize to give RR. The effect of Cu^{2+} ions[424] is to oxidize the radicals to alkenes, thus producing good yields of alkenes from primary and secondary substrates. The Cu^{2+} ion has no effect on tertiary radicals, because these are efficiently oxidized to alkenes by lead tetraacetate.



In another type of oxidative decarboxylation, arylacetic acids can be oxidized to aldehydes with one less carbon ($ArCH_2COOH \rightarrow ArCHO$) by tetrabutylammonium periodate.[425] Simple aliphatic carboxylic acids were converted to nitriles with one less carbon ($RCH_2COOH \rightarrow RC{\equiv}N$) by treatment with trifluoroacetic anhydride and $NaNO_2$ in F_3CCO_2H.[426]

See also, Reaction **14-37**.

19-13 Bis(decarboxylation)

Dicarboxy-elimination

Compounds containing carboxyl groups on adjacent carbons (succinic acid derivatives) can be bis(decarboxylated) with lead tetraacetate in the presence of O_2.[417] The reaction is of wide scope. The elimination is stereoselective, but not stereospecific (both *meso*- and

dl-2,3-diphenylsuccinic acid gave *trans*-stilbene)[427]; a concerted mechanism is thus unlikely. The following mechanism is compatible with the data:

though a free radical mechanism seems to hold in some cases. Bis(decarboxylation) of succinic acid derivatives to give alkenes[428] has also been carried out by other methods.[429] Compounds containing geminal carboxyl groups (disubstituted malonic acid derivatives) can be bis(decarboxylated) with lead tetraacetate,[430] *gem*-diacetates (acylals) being produced, which are easily hydrolyzable to ketones:[431]

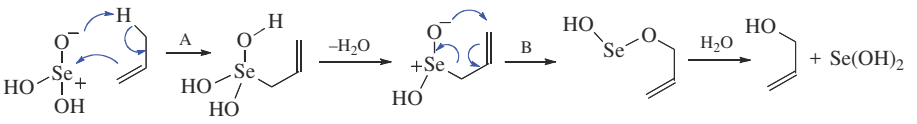
A related reaction involves α-substituted aryl nitriles having a sufficiently acidic α hydrogen, which can be converted to ketones by oxidation with air under phase-transfer conditions.[432] The nitrile is added to NaOH in benzene or DMSO, containing a catalytic amount of triethylbenzylammonium chloride (TEBA).[433] This reaction could not be applied to aliphatic nitriles, but an indirect method for achieving this conversion is given in Reaction **19-60**.

C. Reactions Involving Replacement of Hydrogen by Heteroatoms

19-14 Hydroxylation at an Aliphatic Carbon

Hydroxylation or **Hydroxy-de-hydrogenation**

$$R_3CH \xrightarrow[\text{silica gel}]{O_3} R_3COH$$



Compounds containing susceptible C—H bonds can be oxidized to alcohols.[434] Nearly always, the C—H bond involved is tertiary, so the product is a tertiary alcohol. This is partly because tertiary C—H bonds are more susceptible to free radical attack than primary and secondary bonds and partly because the reagents involved would oxidize primary and

secondary alcohols further. In the best method, the reagent is ozone and the substrate is absorbed on silica gel.[435] Yields as high as 99% have been obtained by this method. Other reagents are chromic acid,[436] ruthenium tetroxide (RuO_4),[437] thallium acetate,[438] sodium chlorite ($NaClO_2$) with a metalloporphyrin catalyst,[439] OsO_4,[440] and certain peroxybenzoic acids.[441] Alkanes and cycloalkanes have been oxidized at secondary positions, to a mixture of alcohols and trifluoroacetates, by 30% aq H_2O_2 in trifluoroacetic acid.[442] This reagent does not oxidize the alcohols further and ketones are not found. As in the case of chlorination with *N*-haloamines and sulfuric acid (see Reaction **14-1**), the $\omega - 1$ position is the most favored. Another reagent[443] that oxidizes secondary positions is iodosylbenzene, catalyzed by Fe(III)–porphyrin catalysts.[444] Use of an optically active Fe(III)–porphyrin gave modest enantioselective hydroxylation.[445]

When chromic acid is the reagent, the mechanism is probably as follows: a Cr^{6+} species abstracts a hydrogen to give $R_3C^{\bullet}$, which is held in a solvent cage near the resulting Cr^{5+} species. The two species then combine to give R_3COCr^{4+}, which is hydrolyzed to the alcohol. This mechanism predicts retention of configuration; this is largely observed.[446] The oxidation by permanganate also involves predominant retention of configuration, and a similar mechanism has been proposed.[447]

Treatment of double-bond compounds with selenium dioxide introduces an OH group into the allylic position (see also, Reaction **19-17**).[448] This reaction also produces conjugated aldehydes in some cases.[449] Allylic rearrangements are common. There is evidence that the mechanism does not involve free radicals, but includes two pericyclic steps (**A** and **B**):[450]

The step marked **A** is similar to the ene reaction (Reaction **15-23**). The step marked **B** is a [2,3]-sigmatropic rearrangement (see Reaction **18-35**). The reaction can also be

accomplished with *tert*-butyl hydroperoxide, if SeO_2 is present in catalytic amounts (the *Sharpless method*).[451] The SeO_2 is the actual reagent; the peroxide reoxidizes the $Se(OH)_2$.[452] This method makes work up easier, but gives significant amounts of side products when the double bond is in a ring.[453] Alkynes generally give α,α′ dihydroxylation.[454] Allylic hydroxylation[455] with selenium dioxide often gives aldehydes, but in the presence of acetic anhydride and oxygen, SeO_2 converts alkenes to homoallylic acetates as the major product, C=C—C—C → C=C—C—C—OAc.[456]

Hydroxylation of unactivated sp^3 hybridized bonds is possible using an oxaziridine-mediated, organocatalyzed reaction.[457] Ruthenium tetroxide oxidizes alkanes.[458] Nanocrystalline cobalt oxide is another catalyst for alkane oxidation.[459] The H_2O_2—$NaVO_3$—H_2SO_4 system facilitates alkane oxidation in aqueous acetonitrile.[460]

Benzylic methylene groups are more readily oxidized to benzylic alcohols when compared to simple alkanes. Typical reagents include manganese salen and PhIO[461] or peroxides.[462] Oxidation to an acetoxy benzyl derivative was accomplished with $PhI(OAc)_2$ in acetic acid with a Pd catalyst,[463] and with PhI(OH)OTs in aq DMSO.[464] With minimal water, cerium (IV) triflate converts benzylic arenes to benzylic alcohols, although the major product is the ketone when >15% of water is present.[465]

Allylic benzyloxylation occurs when an alkene is treated with *t*-BuOOCOPh and a Cu—Na zeolite,[466] a Cu catalyst,[467] or with a chiral Cu catalyst to give modest enantioselectivity.[468] Allylic methylene groups can be converted to ester (—CH—OCOR) derivatives in a similar manner using copper triflate.[469] Cupric acetate has been used,[470] as well as Cu_2O.[471] A chiral Lewis acid has been used for an enantioselective allylic CH oxidation to an allylic acyl derivative.[472] α-Acetoxylation of allylic alkenes can proceed with allylic rearrangement.[473]

Hydroxylation can be accomplished using enzymatic systems. In the presence of *Bacillus megaterium* and oxygen, cyclohexane is converted to cyclohexanol.[474] Allylic oxidation to an allylic alcohol was accomplished with cultured cells of *Gossypium hirsutum*.[475] Benzylic arenes are converted to the corresponding α-hydroxy compound by treatment with the enzymes of *B. megaterium*, with modest enantioselectivity.[476] The reaction of tetradecanoic acid with the α-oxidase from *Pisum sativum*, in the presence of molecular oxygen, gives 2(*R*)-hydroxytetradecanoic acid with high asymmetric induction.[477]

Simple alkanes can be converted to esters with dialkyloxiranes. Cyclic alkanes are oxidized to alcohols with dimethyl dioxirane.[478] Cyclohexane was converted to cyclohexyl trifluoroacetate with di(trifluoromethyl) dioxirane and trifluoroacetic anhydride[479] and also with $RuCl_3/MeCO_3H/CF_3CO_2H$.[480] Dimethyl dioxirane converts alkanes to alcohols in some cases.[481] Adamantane is converted to adamantyl alcohol with DDQ (see Reaction **19-1**, category 3) and triflic acid.[482] The mechanism of oxygen insertion into alkanes has been examined.[483]

It is possible to perform the conversion $CH_2 \rightarrow C{=}O$ on an alkane, with no functional groups at all, although the most success has been achieved with substrates in which all CH_2 groups are equivalent (e.g., unsubstituted cycloalkanes). Hydrogen peroxide and trifluoroacetic acid has also been used for oxidation of alkanes.[484] With this method, cyclohexane was converted with 72% efficiency to give 95% cyclohexanone and 5% cyclohexanol.[485] The same type of conversion, with lower yields (20–30%), has been achieved with the *Gif system*.[486] There are several variations. One consists of pyridine–acetic acid, with H_2O_2 as oxidizing agent and tris(picolinato)iron(III) as catalyst.[487] Other Gif systems use O_2 as oxidizing agent and Zn as a reductant.[488] The selectivity of the Gif systems toward alkyl carbons is $CH_2 > CH \geq CH_3$, which is unusual, and shows that a simple free radical mechanism (see Sec. 14.A.iv) is not involved.[489] Another reagent that can oxidize the CH_2 of an alkane is methyl(trifluoromethyl)dioxirane, but this produces CH—OH more often

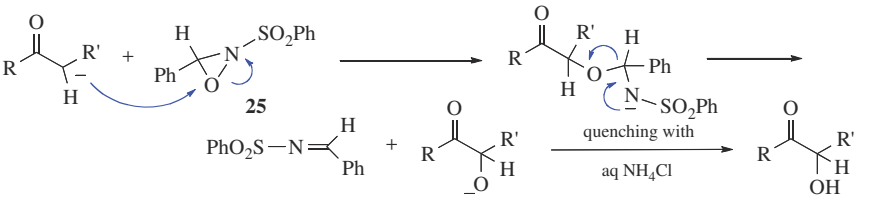
19-15 Oxidation of Methylene to OH, O_2CR, or OR

Hydroxy (or alkoxy) -de-dihydro-bisubstitution



Methyl or methylene groups α to a carbonyl can be oxidized to give α-hydroxy ketones, aldehydes, or carboxylic acid derivatives. Ketones can be α hydroxylated in good yields, without conversion to the enolates, by treatment with the hypervalent iodine reagents[493] *o*-iodosobenzoic acid.[494] Dioxygen (O_2) and a chiral phase-transfer catalyst gave enantioselective α hydroxylation of ketones, if the α position was tertiary.[495] Dimethyl dioxirane is quite effective for hydroxylation of 1,3-dicarbonyl compounds,[496] and O_2 with a Mn catalyst also gives hydroxylation.[497] Oxygen with a Ce catalyst α-hydroxylates β-keto esters.[498] The Pd—C catalyzed α-oxygenation of 1,3-dicarbonyl compounds can be accomplished using O_2.[499] An engineered Cytochrome P450 BM-3 is effective for the enantioselective α-hydroxylation of esters of benzylic acids.[500] The reaction of ketones with $Ti(OiPr)_4$, diethyl tartrate and *tert*-butylhydroperoxide gave the α-hydroxy ketone with good enantioselectively, albeit in low yield.[501] α-Hydroxylation of ketones was reported using H_2O_2 and 12-tungstophosphoric acid–cetylpyridinium chloride as a catalyst.[502] Hypervalent iodine(III) sulfonate has been used for the α-hydroxylation of aryl ketones.[503]

Ketones and carboxylic esters can be α hydroxylated by treatment of their enolate anions (prepared by adding the ketone or ester to LDA) with a Mo peroxide reagent (MoO_5–pyridine–HMPA; called MoOPH) in THF–hexane at −70°C.[504] The enolate forms of amides and esters[505] and the enamine derivatives of ketones[506] can similarly be

converted to their α-hydroxy derivatives by reaction with molecular oxygen. The MoO_5 method can also be applied to certain nitriles.[507]

Ketones are converted to α-hydroxy ketones by reaction of the enolate anion with a 2-sulfonyloxaziridine (e.g., **25**).[508] This is not a free radical process; the mechanism shown is likely. The method is also successful for carboxylic esters[509] and *N,N*-disubstituted amides,[510] and can be made enantioselective by the use of a chiral oxaziridine.[511] Dimethyldioxirane also oxidizes the enolate anions of ketones to α-hydroxy ketones.[512] Titanium enolates are oxidized with *tert*-butyl hydroperoxide[513] or with dimethyldioxirane[514] and hydrolyzed with aq ammonium fluoride to give the α-hydroxy ketone. Ketones are converted to the α-oxamino derivative (O=C—CH_2— → O=C—CHONHPh) with excellent enantioselectivity using PhN=O and L-proline[515] or (*S*)-proline.[516] Aldehydes undergo a similar oxidation.[517] α-Lithio sulfones have been hydroxylated with Me_3SiOOt-Bu.[518]

Dimethyldioxirane

Ketones have been α hydroxylated by conversion to the silyl enol ether, followed by treatment with *m*-chloroperoxybenzoic acid,[166] or with certain other oxidizing agents.[519] α-Hydroxyketones can be accomplished from silyl enol ethers with a catalytic amount of $MeReO_3$ and H_2O_2.[520] When the silyl enol ethers are treated with iodosobenzene in the presence of trimethylsilyl trifluoromethyl sulfonate, the product is the α-keto triflate.[521]

Silyl ketene ethers are converted to α-hydroxy esters with H_2O_2 and methyl trioxorhenium.[522] The α′-position of α,β-unsaturated ketones can be selectively oxidized.[523] *N*-Acyl amines are converted to the α-hydroxy derivative with PhIO and a Mn salen catalyst.[524] Note that homoallylic-type oxidation occurs when an α,α-dimethyl oxime ether is treated with $PhI(OAc)_2$ and a Pd catalyst in acetic acid/acetic anhydride, converting one of the methyl groups to an acetoxymethyl.[525]

α-Acetoxylation of ketones with concurrent α-arylation occurs when ketones react with $Mn(OAc)_3$ in benzene.[526] α-Acetoxylation of ketones can occur under similar conditions without arylation.[527] α-Methyl ketones are converted to the α-acetoxy derivative under the same conditions.[528] Iodobenzene with 30% aq H_2O_2 and acetic anhydride generates α-acetoxy ketones.[529] Thallium(III) triflate converts acetophenone to α-formyloxy acetophenone.[530] Methanesulfonic acid and CuO converts ketones to α-mesyloxy (—OMs) ketones[531] and PhI(OH)OTs converts ketones to α-tosyloxy (—OTs) ketones.[532] *N*-Methyl-*O*-tosylhydroxylamine is another reagent that effects direct α-oxytosylation of ketones and aldehydes.[533] α-Acetoxylation of ketones results from *in situ* generation of hypervalent iodine species in the presence of acetic acid.[534]

OSCV 7, 277; OSCV 7, 263; OSCV 6, 43

19-16 Oxidation of Methylene to Heteroatom Functional Groups Other Than Oxygen or Carbonyl

Amino (or amido) -de-dihydro-bisubstitution

α-Amination or amidation of a CH unit is possible in some cases. Cyclic alkanes are converted to the *N*-alkyl *N*-tosylamine with PhI=NTs and a Cu complex.[535] Benzylic (CH) as in ethylbenzene, is oxidized with $PhI(OAc)_2$ in the presence of $TsNH_2$ and a fluorinated manganese porphyrin to give the corresponding *N*-tosylamine [PhCHMe(NHTs)].[536] Alkenes with an allylic CH react with PhI=NTs and a Ru catalysts to give an allylic

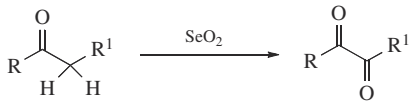
N-tosylamine.[537] When an α-keto ester reacts with DEAD and a chiral Cu complex, an α-carbamate is formed, $RCH(NHCO_2Et)C(=O)CO_2Et$, with modest enantioselectivity.[538]

Cyclic amines react with *Pseudomonas oleovorans* GPol to give hydroxy amines; *N*-benzylpyrrolidine is converted to 3-hydroxy *N*-benzylpyrrolidine.[539] *Sphingomonas* sp. HXN-200 gives similar results,[540] and lactams are converted to the corresponding 3-hydroxy lactam with *sphingomonas* sp. HXN-200.[541] *N*-Benzyl piperidine is converted to the 4-hydroxy derivative under the same conditions.[542] *N*-Benzyl phthalimide reacts with NBS, NaOAc, and acetic acid to give *N*-(α-acetoxybenzyl)phthalimide.[543]

Tetrahydrofuran was converted to the hemiacetal 2-hydroxytetrahydrofuran, which was relatively stable under the conditions used, by electrolysis in water.[544] α-Hydroxy ethers are generated by reaction of SO_2/O_2 and a V catalyst with ethers.[545]

Similar reactions are possible, in some cases, to produce sulfur containing compounds.

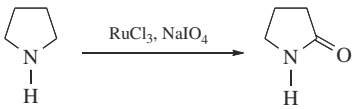


Sulfo-de-dihydro-bisubstitution

Cyclic alkanes are converted to the corresponding alkylsulfonic acid with SO_2/O_2 and a V catalyst.[546]

19-17 Oxidation of Methylene to Carbonyl

Oxo-de-dihydro-bisubstitution



Methyl or methylene groups α to a carbonyl can be oxidized with selenium dioxide to give, respectively, α-keto aldehydes (see Reaction **19-18**) and α-diketones.[547] The reaction can also be carried out α to an aromatic ring or to a double bond, although in the latter case, hydroxylation (see **19-14**) is the more common result. Selenium dioxide, (SeO_2) is often used, but the reaction has also been carried out with other oxidizing agents,[548] including hypervalent iodine compounds.[549] Sodium nitrite/HCl oxidizes cyclic ketones to the diketone.[550] Substrates most easily oxidized contain two aryl groups on CH_2, and these substrates can be oxidized with many oxidizing agents (see Reaction **19-11**). The benzylic

a Hg(II)—EDTA (EDTA = ethylenediaminetetraacetic acid) complex in basic solution.[576] Lactams, which need not be *N*-substituted, can be converted to cyclic imides by oxidation with a hydroperoxide or peroxyacid and an Mn(II) or Mn(III) salt.[577] Lactams are oxidized to cyclic imides with oxygen and $Co(OAc)_2$ in the presence *N*-hydroxysuccinimide.[578]

Ethers in which at least one group is a primary alkyl can be oxidized to the corresponding carboxylic esters in high yields with ruthenium tetroxide.[579] Molecular oxygen with a binuclear Cu(II) complex[580] or $PdCl_2/CuCl_2/CO$[581] also converts ethers to esters. Cyclic ethers are oxidized to lactones.[582] Cyclic ethers are oxidized to lactones with CrO_3/Me_3SiONO_2.[583] Lactones are also formed from cyclic ethers with $NaBrO_3—KHSO_4$ in water.[584] The reaction has also been accomplished with CrO_3 in H_2SO_4,[585] and with benzyltriethylammonium permanganate.[586]

Two mechanisms have been suggested for the reaction with SeO_2. One of these involves a selenate ester of the enol:[587]

In the other proposed mechanism,[588] the principal intermediate is α,β-ketoseleninic acid (O=C—CH—SeO_2H) and a selenate ester is not involved.

Oxidation of CH_2 to C=O groups is possible even if they are not near any functional groups, indirectly, by the remote oxidation method of Breslow[57] (see Reaction **19-2**). One of the CH_2 groups of *n*-hexadecanol monosuccinate [$CH_3(CH_2)_{14}CH_2OCOCH_2CH_2CO_2H$] was oxidized to a C=O group to give a mixture of it and benzophenone-4-carboxylic acid [*p*-$PhCOC_6H_4CO_2H$] in CCl_4.[589] Other remote oxidations[590] also have been reported. Among these are conversion of aryl ketones [$ArCO(CH_2)_3R$] to 1,4-diketones [$ArCO(CH_2)_4COR$] by photoirradiation in the presence of such oxidizing agents as $K_2Cr_2O_7$ or $KMnO_4$,[591] and conversion of alkyl ketones [$RCO(CH_2)_3R'$] to 1,3- and 1,4-diketones with

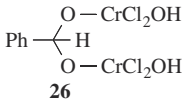
19-18 Oxidation of Arylmethanes to Aldehydes

Oxo-de-dihydro-bisubstitution

$$ArCH_3 \xrightarrow{CrO_2Cl_2} ArCHO$$

Methyl groups on an aromatic ring can be oxidized to an aldehyde by several oxidizing agents. The reaction is a special case of **19-17**. When the reagent is chromyl chloride (CrO_2Cl_2), the reaction is called the *Étard reaction*[594] and the yields are high.[595] Another oxidizing agent is a mixture of CrO_3 and Ac_2O, where the reaction stops at the aldehyde stage because the initial product is $ArCH(OAc)_2$ (an acylal), which is resistant to further oxidation. Hydrolysis of the acylal gives the aldehyde.



Among other oxidizing agents[596] that have been used to accomplish the conversion of $ArCH_3$ to ArCHO are ceric ammonium nitrate,[597] PCC,[598] hypervalent iodoso compounds (see Reaction **19-3**),[599] Bi-*t*-BuOOH,[600] and urea–H_2O_2 with microwave irradiation.[601] Oxidative of benzylic positions to the corresponding carbonyl has been reported using two heterogeneous catalysts.[602] Oxidation of $ArCH_3$ to carboxylic acids is considered at Reaction **19-11**.

Conversion of $ArCH_3$ to ArCHO can also be achieved indirectly by bromination to give $ArCHBr_2$ (**14-1**), followed by hydrolysis (Reaction **10-2**).

The mechanism of the *Étard reaction* is not completely known.[603] An insoluble complex is formed on addition of the reagents, which is hydrolyzed to the aldehyde. The complex is probably a kind of acylal, but the identity of the structure is not fully settled, although many proposals have been made as to its structure and as to how it is hydrolyzed. It is known that $ArCH_2Cl$ is not an intermediate (see Reaction **19-20**), since it reacts only very slowly with chromyl chloride. Magnetic susceptibility measurements[604] indicate that the complex from toluene is **26**, a structure first proposed by Étard. According to this proposal, the reaction

stops after only two hydrogen atoms have been replaced because of the insolubility of **26**. There is a disagreement on how **26** is formed, assuming that the complex has this structure. Both an ionic[605] and a free radical[606] process have been proposed. An entirely different structure for the complex was proposed by Nenitzescu et al.[607] On the basis of ESR studies, they proposed that the complex is $PhCH_2OCrCl_2OCrOCl_2OH$, which is isomeric with **26**. However, this view has been challenged by Wiberg and Eisenthal,[606] who interpret the ESR result as being in accord with **26**. Still another proposal is that the complex is composed of benzaldehyde coordinated with reduced chromyl chloride.[608]

19-19 Oxidation of Aromatic Hydrocarbons to Quinones

Arene-quinone transformation

Condensed aromatic systems (including naphthalenes) can be directly oxidized to quinones by various oxidizing agents.[609] Yields are generally not high, although good yields have been reported with ceric ammonium sulfate.[610] Benzene cannot be so oxidized by strong oxidizing agents, but can be electrolytically oxidized to benzoquinone.[611] Naphthalene derivatives, however, are oxidized to naphthoquinones with H_5IO_6 and CrO_3.[612] 1,4-Dimethoxy aromatic compounds are oxidized to *p*-quinones with an excess of CoF_3 in water–dioxane.[613]

19-20 Oxidation of Primary Halides and Esters of Primary Alcohols to Aldehydes[614]

Oxo-de-hydro,halo-bisubstitution

$$RCH_2Cl \xrightarrow{Me_2SO} RCHO$$

Primary alkyl halides (chlorides, bromides, and iodides) can be oxidized to aldehydes easily and in good yields with DMSO,[615] in what has been called the *Kornblum reaction*. In Kornblum's original work, the reaction of α-halo ketones with DMSO at elevated temperatures gave good yields of the corresponding glyoxal (an α-keto-aldehyde).[616] If the glyoxal could be removed from the reaction medium by distillation as it was formed, the reaction was very efficient. In many cases, it was difficult to isolate high-boiling glyoxals from DMSO. Primary and secondary[617] alkyl iodides or tosylates[618] can be converted to aldehydes or ketones, although they are much less reactive than α-halo ketones. Primary chlorides with DMSO, NaBr, and ZnO give the corresponding aldehyde when heated to 140 °C.[619] Benzylic halides are oxidized to aryl aldehydes with MnO_2[620] or with $NaIO_4$—LiBr.[621] Hydrogen peroxide in ethanol oxidizes organic halides to carbonyl compounds.[622] Pyridine *N*-oxide in the presence of silver oxide oxidizes benzylic and allylic halides.[623]

The mechanism of these DMSO oxidations is probably that shown with **27** and **28**,[624] although in some cases the base abstracts a proton directly from the carbon being oxidized, in which case the ylid (**28**) is not an intermediate. Alkoxysulfonium salts (**27**) have been isolated.[625] This mechanism predicts that secondary compounds should be oxidizable to ketones, and this is the case. In a related procedure for the oxidation of alcohols, the

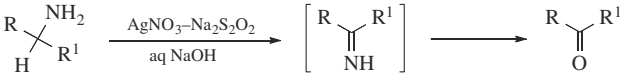
intermediate **27**[626] is formed without the use of DMSO by treating the substrate with a complex generated from chlorine or NCS and DMS.[627] Also see the *Swern oxidation* in Reaction **19-3**.

Another way to oxidize primary alkyl halides to aldehydes is by the use of hexamethylenetetramine followed by water. However, this reaction, called the *Sommelet reaction*,[628] is limited to benzylic halides. The reaction is seldom useful when the R in RCH_2Cl is alkyl. The first part of the reaction is conversion to the amine ($ArCH_2NH_2$), which can be isolated. Reaction of the amine with excess hexamethylenetetramine gives the aldehyde. It is this last step that is the actual *Sommelet reaction*, although the entire process can be conducted without isolation of intermediates. Once the amine is formed, it is converted to an imine ($ArCH_2N{=}CH_2$) with formaldehyde liberated from the reagent. The key step then follows: transfer of hydrogen from another mole of the arylamine to the imine. This last imine is then hydrolyzed by water to the aldehyde. Alternatively, the benzylamine may transfer hydrogen directly to hexamethylenetetramine.



Pyridine followed by *p*-nitrosodimethylaniline and then water converts benzylic halides to aldehydes, and is called the *Kröhnke reaction*. Primary halides and tosylates have been oxidized to aldehydes by trimethylamine *N*-oxide,[629] and by pyridine *N*-oxide with microwave irradiation.[630]

Epoxides[631] have been used to give α-hydroxy ketones or aldehydes.[632]

Primary, secondary, and tertiary aliphatic amines have been cleaved to give aldehydes, ketones, or carboxylic acids with aq bromine[638] and with neutral permanganate.[639] The other product of this reaction is the amine with one less alkyl group. Reaction of a primary amine with benzoyl peroxide/$CsCO_3$ and subsequent heating of the hydroxylamine product gives the ketone.[640] In a different type of procedure, primary alkyl primary amines can be converted to *gem*-dihalides [$RCH_2NH_2 \rightarrow RCHX_2$ (X = Br or Cl)] by treatment with an alkyl nitrite and the anhydrous copper(I) halide.[641]

Primary and secondary aliphatic nitro compounds have been oxidized to aldehydes and ketones, respectively ($RR'CHNO_2 \rightarrow RR'C{=}O$), with sodium chlorite under phase-transfer conditions,[642] tetrapropylammonium perruthenate (TPAP),[643] as well as with other reagents.[644]

19-22 Oxidation of Primary Alcohols to Carboxylic Acids or Carboxylic Esters

Oxo-de-dihydro-bisubstitution

$$RCH_2OH \xrightarrow{CrO_3} RCOOH$$

Primary alcohols can be oxidized to carboxylic acids by many strong oxidizing agents including chromic acid, permanganate,[645] nitric acid,[646] or H_5IO_6/CrO_3.[647] The reaction can be looked on as a combination of **19-3** and **19-23**. Aliphatic primary alcohols are converted to the carboxylic acid with 30% aq H_2O_2, tetrabutylammonium hydrogen sulfate and a W catalyst with microwave irradiation.[648] Benzylic alcohols are oxidized to benzoic acid derivatives by treatment first with TEMPO[649] (Sec. 5.C.i), and then $NaClO_2$.[650] Oxidation with 5% aq NaOCl and a Ni catalyst oxidizes primary alcohols to the corresponding acid.[651] Similar oxidation to the acid occurred with $NaIO_4/RuCl_3$ in aq acetonitrile,[652] or 30% aq H_2O_2 and a Co salen catalyst.[653] Oxammonium salts and $NaClO_2$ oxidize alcohols to carboxylic acids.[654]

When acidic conditions are used, a considerable amount of carboxylic ester ($RCOOCH_2R$) is often isolated, although this is probably not formed by a combination of the acid with unreacted alcohol, but by a combination of intermediate aldehyde with unreacted alcohol to give an acetal or hemiacetal, which is oxidized to the ester.[655] A mixture of Oxone and NaCl converts alcohols to symmetrical esters.[656] Aliphatic alcohols are converted to a symmetrical ester ($RCH_2OH \rightarrow RCOOCH_2R$) by oxidation with PCC on aluminum without solvent.[657] Hydrogen with a Ru—CO complex converts primary alcohols (ROH) to an ester (RCO_2R).[658] Iodine has been used to convert alcohols to esters.[659] Hydrogen transfer with a Ru catalyst has been used to convert primary alcohols to methyl esters.[660] Oxone in aq methanol also converts aryl aldehydes to the corresponding ester.[661] Allylic alcohols are converted to conjugated esters with MnO_2 and NaCN in methanol–acetic acid.[662] Primary alcohols are oxidized to the methyl ester with trichloroisocyanuric acid in methanol.[663] This reagent also converts diols to lactones. Lactones can be prepared by oxidizing diols in which at least one OH is primary,[664] and addition of a chiral additive (e.g., sparteine) leads to lactones with high asymmetric induction.[665]

Primary alcohols (RCH_2OH) can be directly oxidized to acyl fluorides (RCOF) with cesium fluoroxysulfate.[666] 2-(3-Hydroxypropyl)aniline was oxidized to an acyl derivative that cyclized to give a lactam when heated with a Rh catalyst.[667]

19-23 Oxidation of Aldehydes to Carboxylic Acids, Carboxylic Esters, and Related Compounds

Hydroxylation or Hydroxy-de-hydrogenation

Oxidation of aldehydes to carboxylic acids is quite common[668] and has been carried out with many oxidizing agents, including permanganate in acid, basic, or neutral solution,[669]

chromic acid,[670] bromine, and Oxone.[671] Silver oxide is a fairly specific oxidizing agent for aldehydes and does not readily attack other groups. *Benedict's* and *Fehling's solutions* oxidize aldehydes,[672] and there is a test for aldehydes that depends on this reaction, but the method is seldom used for preparative purposes and gives very poor results with aromatic aldehydes. α,β-Unsaturated aldehydes can be oxidized by sodium chlorite without disturbing the double bond.[673] Aldehydes are also oxidized to carboxylic acids by atmospheric oxygen, but the actual direct oxidation product in this case is the peroxy acid (RCO_3H),[674] which with another molecule of aldehyde disproportionates to give two molecules of acid (see Reaction **14-7**).[675] The air oxidation of aldehydes to carboxylic acids is mediated by a mixture of Pd/C—$NaBH_4$ and KOH.[676] An aldehyde can be converted to the carboxylic acid by treatment with 30% H_2O_2 and methyl(trioctyl) ammonium hydrogen sulfate at 90 °C.[677] Aryl aldehydes are similarly oxidized by a mixture of H_2O_2 and selenium dioxide (SeO_2).[678] Polymer-bound hypervalent iodine + TEMPO oxidizes aldehydes to acids.[679] Hydrogen peroxide oxidizes aldehydes to carboxylic acids in the presence of a $AgNO_3$ catalyst[680] or a Pd catalyst.[681]

Aryl aldehydes are converted to the corresponding aryl carboxylic ester with H_2O_2 and a V_2O_5 catalyst[682] or a titanosilicate[683] in an alcohol solvent. Esterification of aldehydes with alcohols uses an Ir catalyst.[684] The reaction of aldehydes with aq alcohols, in the presence of iodine and $NaNO_2$, gives an ester.[685] Organoboronic acids and molecular oxygen convert aldehydes to an ester using a Pd catalyst.[686] *N*-heterocyclic carbenes catalyze oxidation of aldehydes to the corresponding ester.[687] Aldehydes (RCHO) can be directly converted to carboxylic esters ($RCOOR'$) by treatment with Br_2 in the presence of an alcohol.[688]

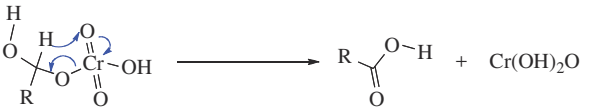
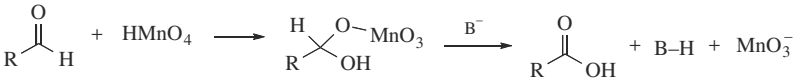
Aldehydes react with amines, mediated by La catalysts, to give amides.[689]

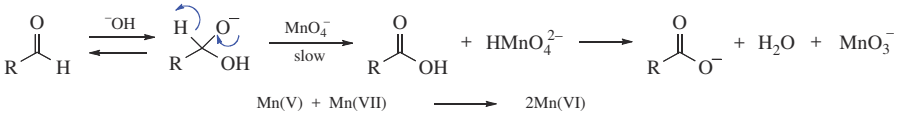
Mechanisms of aldehyde oxidation[690] are not firmly established, but there are at least two main types: a free radical mechanism and an ionic one. In the free radical process, the aldehyde hydrogen is abstracted to leave an acyl radical, which obtains OH from the oxidizing agent. In the ionic process, the first step is addition of a species ^{-}OZ to the carbonyl bond to give **29** in alkaline solution and **30** in acid or neutral solution. The aldehyde hydrogen of **29** or **30** is then lost as a proton to a base, while Z leaves with its electron pair.



For oxidation with acid dichromate the picture seems to be quite complex, with several processes of both types going on:[691]



Steps 1 and 2 constitute an oxidation by the ionic pathway by Cr(VI), and steps 6 and 7 a similar oxidation by Cr(V), which is produced by an electron-transfer process. Either Cr(VI) (step 3) or Cr(IV) (step 4) [Cr(IV) is produced in step 2] may abstract a hydrogen and the resulting acyl radical is converted to carboxylic acid in step 5. Thus, Cr in three oxidation states is instrumental in oxidizing aldehydes. Still another possible process has been proposed in which the chromic acid ester decomposes as follows:[692]



[689] Seo, S.Y.; Marks, T.J. *Org. Lett.* ***2008****, 10*, 317.

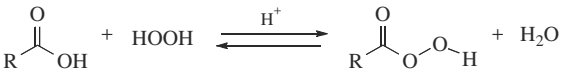
[692] See Rocek, J.; Ng, C. *J. Org. Chem.* ***1973****, 38*, 3348.

The mechanism with permanganate is less well known, but an ionic mechanism has been proposed[693] for neutral and acid permanganate, similar to steps 1 and 2 for dichromate:

For alkaline permanganate, the following mechanism has been proposed:[694]

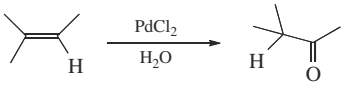


OS **I**, 166; **II**, 302, 315, 538; **III**, 745; **IV**, 302, 493, 499, 919, 972, 974.

The conversion of thioketones to sulfines ($R_2C{=}S{=}O$) is difficult to categorize into the sections available, and it placed after oxidation of ketones and aldehydes. The reaction of a thioketone with H_2O_2 and a catalytic amount of MTO (methyl trioxorhenium) gives the sulfine.[695]

19-24 Oxidation of Carboxylic Acids to Peroxy Acids

Peroxy-de-hydroxy-substitution



The oxidation of carboxylic acids with H_2O_2 and an acid catalyst is the best general method for the preparation of peroxy acids.[696] A mixture of $Me_2C(OMe)OOH$ and DCC has also been used.[697] Concentrated H_2SO_4 is a common catalyst for aliphatic R. The reaction is in equilibrium and is driven to the right by removal of water or by the use of excess reagents. For aromatic R, the best catalyst is methanesulfonic acid, which is also used as the solvent.

D. Reactions in which Oxygen Is Added to the Substrate

19-25 Oxidation of Alkenes to Aldehydes and Ketones

1/Oxo-(1/→2/hydro)-*migro*-attachment

Monosubstituted and 1,2-disubstituted alkenes can be oxidized to aldehydes and ketones by $PdCl_2$, where the $PdCl_2$ is reduced to Pd.[698] Similar salts of noble metals also work, but 1,1-disubstituted alkenes generally give poor results. The reaction is used industrially to prepare acetaldehyde from ethylene (the *Wacker process*),[699] but it is also suitable for laboratory preparations. The reagent is expensive, so the reaction is usually carried out with a cooxidant, often $CuCl_2$, whose function is to reoxidize the Pd to Pd(II). The $CuCl_2$ is reduced to Cu(I), which itself is reoxidized to Cu(II) by air, so that atmospheric oxygen is the only oxidizing agent actually used up. Many other cooxidants have been tried, among them O_3, Fe^{3+}, and PbO_2. Terminal alkenes are oxidized to methyl ketones with O_2 and a Pd catalyst.[700] The principal product is an aldehyde only from ethylene: With other alkenes *Markovnikov's rule* is followed, and ketones are formed predominantly.

The generally accepted mechanism shown below involves π complexes of Pd.[701] This mechanism accounts for the fact, established by deuterium labeling, that the four hydrogen atoms of the acetaldehyde all come from the original ethylene and none from the solvent.

Similar reactions have been carried out with other oxidizing agents. An example involving migration of an alkyl group instead of hydrogen is oxidation of $Me_2C{=}CMe_2$ with peroxytrifluoroacetic acid–boron trifluoride to give Me_3COMe (pinacolone).[702] This reaction consists of epoxidation (**15-50**) followed by pinacol rearrangement of the epoxide (**18-2**). A migration is also involved in the conversion of $ArCH{=}CHCH_3$ to $ArCH(CH_3)CHO$ by treatment with $I_2{-}Ag_2O$ in aq dioxane.[703]

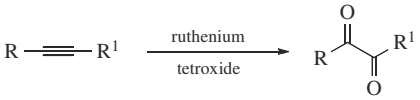
[703] Kikuchi, H.; Kogure, K.; Toyoda, M. *Chem. Lett.* ***1984***, 341.

Other reagents used have been $Pb(OAc)_4$—F_3CCO_2H[704] (e.g., $PhCH{=}CH_2 \rightarrow PhCH_2CHO$), H_2O_2 and a Pd catalyst,[705] H_2O—$PdCl_2$–polyethylene glycol.[706] Terminal alkenes react with ceric ammonium nitrate in methanol to give α-methoxy ketones.[707]



Alkenes have also been converted to more highly oxidized products. Examples are (1) Treatment with $KMnO_4$ in aq acetone containing acetic acid gives α-hydroxy ketones.[708] (2) 1,2-Disubstituted and trisubstituted alkenes give α-chloro ketones when oxidized with chromyl chloride in acetone: $RCH{=}CR^1R^2 \rightarrow RCOCClR^1R^2$.[709] (3) α-Iodo ketones can be prepared by treating alkenes with bis(*sym*-collidine)iodine(I) tetrafluoroborate.[710] (4) Potassium permanganate in acetic anhydride oxidizes large-ring cycloalkenes to 1,2-diketones.[711]

Enol ethers are oxidized to carboxylic esters ($RCH{=}CHOR' \rightarrow RCH_2COOR'$) with PCC[712] and enamines to α-amino ketones with *N*-sulfonyloxaziridines.[713] Enamines ($R^1R^4C{=}CR^2NR_2^3$, $R^4 \neq H$) do not give these products, but lose the amino group to give α-hydroxy ketones [$R^1R^4C(OH)COR^2$].[713] Carboxylic acids can be prepared from terminal alkynes by conversion of the alkyne to its phenylthio ether ($RC{\equiv}CSPh$) and treatment of this with $HgSO_4$ in HOAc—H_2SO_4.[714] *Aza-Wacker reactions* are known.[715]

OS **VI**, 1028; **VII**, 137; **VIII**, 208.

19-26 The Oxidation of Alkynes to α-Diketones

Dioxo-biaddition

Internal alkynes have been oxidized[716] to α-diketones by several oxidizing agents,[717] including neutral $KMnO_4$,[718] bis(trifluoroacetoxy)iodobenzene,[719] $NaIO_4$—RuO_2,[720]

$MeReO_3/H_2O_2$,[721] or oxygen and a mixture of Pd and Cu catalysts.[722] A Ru complex with a small amount of trifluoroacetic acid converts internal alkynes to the α-diketone.[723] Ozone generally oxidizes triple-bond compounds to carboxylic acids (Reaction **19-9**), but α-diketones are sometimes obtained.[724] Selenium dioxide (SeO_2) with a small amount of H_2SO_4 oxidizes alkynes to α-diketones, as well as arylacetylenes to α-keto acids ($ArC{\equiv}CH \rightarrow ArCOCO_2H$).[725] A mixture of formic acid, methanesulfonic acid and DMSO with an HBr catalyst converts alkynes to α-diketones.[726]

19-27 Oxidation of Amines to Nitroso Compounds and Hydroxylamines and Related *N*-Oxo-de-dihydro-bisubstitution

$$ArNH_2 \xrightarrow{H_2SO_5} Ar{-}N{=}O$$

Primary aromatic amines can be oxidized[727] to nitroso compounds. Most often the conversion is accomplished by *Caro's acid* (H_2SO_5) or with H_2O_2 in HOAc.[728] Other reagents used for this oxidation are sodium perborate[729] H_2O_2 with a Ti complex,[730] HOF generated *in situ*,[731] and Na_2WO_4/H_2O_2.[732] Hydroxylamines, which are probably intermediates in most cases, can sometimes be isolated, but under the reaction conditions they are generally oxidized to the nitroso compounds. Primary aliphatic amines can be oxidized in this manner, but the nitroso compound is stable only if there is no α hydrogen. If there is an α hydrogen, the compound tautomerizes to the oxime.[733]

The mechanism with H_2SO_5 has been postulated to be an example of category 5 (Sec. 19.A).[734]

Secondary amines (R_2NH) are oxidized to hydroxylamines (R_2NHOH), which are resistant to further oxidation, by dimethyldioxirane[735] and by benzoyl peroxide and

Na_2HPO_4.[736] Oxone on silica also oxidizes secondary alcohols to the hydroxylamine.[737] Hydroxylamines are formed when secondary amines react with the enzyme cyclohexanone monooxygenase.[738] Carbamates (e.g., *N*-Boc amines) are converted to the *N*-hydroxy compound with bis(trifluoromethyl)dioxirane.[739] Dialkylamines are oxidized to the *N*-nitroso compound with N_2O_2 on poly(vinylpyrrolidinone).[740]

OS **III**, 334; **VIII**, 93; **80**, 207.

19-28 Oxidation of Primary Amines, Oximes, Azides, Isocyanates, or Nitroso Compounds to Nitro Compounds

$$R_3CNH_2 \xrightarrow{KMnO_4} R_3CNO_2 \qquad R_2{=}NOH \xrightarrow{F_3CCOOOH} R_2CHNO_2$$

Tertiary alkyl primary amines can be oxidized to nitro compounds in excellent yields with $KMnO_4$.[741] This type of nitro compound is not easily prepared in other ways. All classes of primary amine (including primary, secondary, and tertiary alkyl, as well as aryl) are oxidized to nitro compounds in high yields with dimethyldioxirane.[742] Other reagents that oxidize various types of primary amines to nitro compounds are dry ozone,[743] various peroxyacids,[744] $MeReO_3/H_2O_2$,[745] Oxone,[746] *tert*-butyl hydroperoxide in the presence of certain Mo and V compounds,[747] and sodium perborate.[748] An aqueous solution of fluorine oxidizes amino esters to α-nitro esters.[749]

Dimethyldioxirane in wet acetone oxidizes isocyanates to nitro compounds (RNCO $\rightarrow RNO_2$).[750] Oximes can be oxidized to nitro compounds with peroxytrifluoroacetic acid, or sodium perborate,[751] among other ways.[741] Secondary hydroxylamines are also oxidized to nitrones with MnO_2 in dichloromethane.[752] Primary and secondary alkyl azides have been converted to nitro compounds by treatment with Ph_3P followed by ozone.[753] An aqueous solution of fluorine also oxidizes azides to the corresponding nitro

19-29 Oxidation of Tertiary Amines to Amine Oxides

N-Oxygen-attachment

$$R_3N \xrightarrow{H_2O_2} R_3N^+—O^-$$

Tertiary amines can be converted to amine oxides by oxidation. Hydrogen peroxide is often used, but peroxyacids are also important reagents for this purpose. Pyridine and its derivatives are oxidized by peroxyacids[756] rather than hydrogen peroxide. Note, however, that urea–H_2O_2 in formic acid does indeed oxidize pyridine.[757] Oxidation with *Caro's acid* has been shown to proceed in this manner:[758]

This mechanism is the same as that of Reaction **19-27**; the products differ only because tertiary amine oxides cannot be further oxidized. The mechanism with other peroxyacids is probably the same. A green procedure for oxidation of tertiary amines has been developed, using a Mg—Al complex with aq H_2O_2.[759] Nitrones can be prepared using a ball-mill.[760]

An alternative oxidation using O_2 and a $RuCl_3$ catalyst converted pyridine to pyridine *N*-oxide.[761] Bromamine-T and $RuCl_3$ in aq acetonitrile also oxidizes pyridine to the *N*-oxide.[762] Tertiary amines are oxidized to the *N*-oxide with O_2 and Fe_2O_3 in the presence of an aliphatic aldehyde.[763] Oxygen and a Co–Schiff base complex also oxidizes tertiary amines, including pyridine.[764]

Analogous to the oxidation of tertiary amines, tertiary phosphines are oxidized to phosphine oxides ($R_3P=O$). Triphenylphosphine is converted to triphenylphosphine oxide with N_2O at 100 °C, for example. Triphenylphosphine is also oxidized with PhIO on Montmorillonite K-10.[765] *tert*-Butylhydroperoxide oxides $Ph_3P \rightarrow BH_3$ to $Ph_3P=O$.[766] *P*-Stereogenic phosphine oxides have been prepared.[767]

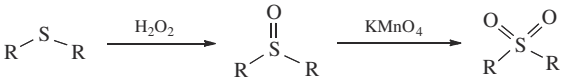
19-30 Oxidation of Thiols and Other Sulfur Compounds to Sulfonic Acids

Thiol-sulfonic acid oxidation



$$RSH \xrightarrow{HNO_3} RSO_3H$$

Thiols, sulfoxides, sulfones, disulfides,[768] and other sulfur compounds can be oxidized to sulfonic acids with various oxidizing agents, but for synthetic purposes the reaction is most important for thiols.[769] Among oxidizing agents used are boiling nitric acid, barium permanganate, and dimethyl dioxirane.[770] Autoxidation (oxidation by atmospheric oxygen) can be accomplished in basic solution.[771] Oxidation of thiols with chlorine and water gives sulfonyl chlorides directly.[772] Thiols can also be oxidized to disulfides (Reaction **19-34**).

OS **II**, 471; **III**, 226. Also see, OS **V**, 1070.

19-31 Oxidation of Thioethers to Sulfoxides and Sulfones

S-Oxygen-attachment

Thioethers can be oxidized to sulfoxides by 1 equiv of 30% H_2O_2 or by many other oxidizing agents,[773] including $NaIO_4$,[774] H_2O_2, and a $Sc(OTf)_3$ catalyst,[775] HIO_3/wet SiO_2,[776] dioxiranes,[777] $MeReO_3/H_2O_2$,[778] O_2 and a ceric ammonium nitrate catalyst,[779] KO_2/Me_3SiCl,[780] hexamethylene triamine–Br_2 with $CHCl_3$—H_2O,[781] $H_5IO_6/FeCl_3$,[782]

hypervalent iodine compounds,[783] and peroxyacids.[784] Sulfoxides can be further oxidized to sulfones by another equivalent of H_2O_2, $KMnO_4$, sodium perborate, or a number of other agents. If enough oxidizing agent is present, thioethers can be directly converted to sulfones without isolation of the sulfoxides.[785] Thioethers can be oxidized directly to the sulfone by treatment with TPAP,[786] H_2O_2[787] and an Fe catalyst,[788] a Zr catalyst,[789] a Ta catalyst,[790] a V catalyst,[791] an Au catalyst,[792] a Mo catalyst,[793] a flavin-ionic liquid catalyst,[794] urea–H_2O_2,[795] peroxy monosulfate and a Mn catalyst,[796] or nitric acid with P_2O_5 on silica gel.[797] These reactions give high yields, and many functional groups do not interfere.[798]

As with tertiary amines (Reaction **19-29**), racemic thioethers can be kinetically resolved by oxidation to sulfoxides with an optically active reagent, and this has often been done.[799] In addition, the use of chiral additives in conjunction with various oxidizing agents leads to chiral nonracemic sulfoxide with good-to-excellent enantioselectivity.[800] Asymmetric oxidation using bacterial monooxygenases is known,[801] and horseradish peroxidase gives modest enantioselectivity.[802] Chiral sulfur reagents are also known.[803] It is possible to oxidize a thioether to a sulfoxide in the presence of an alcohol moiety using MnO_2/HCl.[804] *N*-Sulfonyloxaziridines can be used to oxidize sulfides to sulfoxides.[805] Selenides (R_2Se) can be oxidized to selenoxides and selenones.[806] Alkyl disulfides give oxidation of one

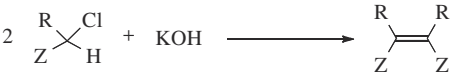
sulfur to give a RS—S(=O)R compound with good enantioselectivity when using aq H_2O_2, a catalytic amount of a V catalyst, and a chiral Schiff base ligand.[807]

When the oxidizing agent is a peroxide, the mechanism[808] of oxidation to the sulfoxide is similar to that of Reaction **19-29**.[809]

The second oxidation, which is normally slower than the first, which is why sulfoxides are so easily isolable, has the same mechanism in neutral or acid solution, but in basic solution it has been shown that the conjugate base of the peroxy compound ($R'OO^-$) also attacks the SO group as a nucleophile:[810]



There are some reagents that oxidize sulfoxides in preference to sulfides (e.g., $NaMnO_4$).[811]

E. Oxidative Coupling

19-32 Coupling Involving Carbanions

De-hydro,chloro-coupling

Alkyl halides with an electron-withdrawing group on the halogen-bearing carbon can be dimerized to alkenes by treatment with bases. The Z group may be nitro, aryl, and so on. It is likely that in most cases the mechanism[812] involves nucleophilic substitution followed by elimination[813] (illustrated for benzyl chloride):

α,α-Dibromotoluenes ($ArCHBr_2$) give tolanes ($ArC{\equiv}CAr$) by debromination of the intermediates ArCBr=CBrAr.[814] In a related reaction, diarylmethane dihalides

(Ar_2CX_2) have been dimerized to tetraaryl alkenes ($Ar_2C{=}CAr_2$) with Cu,[815] and with iron(II) oxalate dihydrate.[816]

A somewhat different type of coupling is observed when salts of β-keto esters, arylacetonitriles ($ArCH_2CN$), and other compounds of the form ZCH_2Z' are treated with an oxidizing agent (e.g., iodine,[817] or Cu(II) salts.][818] Arylmethanesulfonyl chlorides ($ArCH_2SO_2Cl$) couple to give ArCH=CHAr when treated with Et_3N.[819]

19-33 Dimerization of Silyl Enol Ethers or of Lithium Enolates

3/*O*-De-trimethylsilyl-1/*C*-coupling

31

Silyl enol ethers can be dimerized to symmetrical 1,4-diketones by treatment with Ag_2O in DMSO or certain other polar aprotic solvents.[820] The reaction has been performed with R^2, R^3 = hydrogen or alkyl, although best yields are obtained when $R^2 = R^3 = H$. In certain cases, unsymmetrical 1,4-diketones have been prepared by using a mixture of two silyl enol ethers. Other reagents that have been used to achieve either symmetrical or cross-coupled products are iodosobenzene–BF_3–OEt_2,[821] ceric ammonium nitrate,[822] and lead tetraacetate.[823] If R^1 = OR (in which case the substrate is a ketene silyl acetal), dimerization with $TiCl_4$ leads to a dialkyl succinate (**31**, R^1 = OR).[824]

In a similar reaction, lithium enolates [$RC(OLi){=}CH_2$] were dimerized to 1,4-diketones ($RCOCH_2CH_2COR$) with $CuCl_2$, $FeCl_3$, or copper(II) triflate, in a nonprotic solvent.[825]

OS **VIII**, 467.

19-34 Oxidation of Thiols to Disulfides

S-De-hydrogen-coupling

$$2\,RSH \xrightarrow{H_2O_2} RSSR$$

Thiols are easily oxidized to disulfides.[826] Hydrogen peroxide is the most common reagent,[827] but many oxidizing agents give the reaction, among them Br_2 on hydrated

silica,[828] sodium perborate,[829] SmI_2,[830] PPh_3 with a Rh catalyst,[831] cetyltrimethylammonium dichromate,[832] and NO. Hydrogen peroxide (30%) in hexafluoro-2-propanol converts thiols to disulfides,[833] and solventless reactions on MnO_2,[834] PCC (Reaction **19-3**, category 1)[835] or SO_2Cl_2[836] are also effective. A potassium phosphate catalyst has been used for the oxidative coupling of thiols to disulfides.[837] Strong oxidizing agents may give Reaction **19-26**. Even oxygen in the air oxidizes thiols on standing, if a small amount of base is present. The reaction is reversible (see Reaction **19-75**), and the interconversion between cysteine and cystine is an important one in biochemistry.

The mechanism has been studied for several oxidizing agents and varies with the agent.[838] For oxygen it is[839]

$$RSH + B^- \rightleftharpoons RS^- + BH$$

$$RS^- + O_2 \longrightarrow RS\bullet + \bullet O_2^-$$

$$RS^- + \bullet O_2^- \longrightarrow RS\bullet + O_2^{2-}$$

$$2\,O_2^{2-} + 2\,BH \longrightarrow 2\,OH^- + 2\,B^- + O_2$$

With respect to the sulfur, this mechanism is similar to that of Reaction **14-16**, involving as it does loss of a proton, oxidation to a free radical, and radical coupling.

Unsymmetrical disulfides can be prepared[840] by treatment of a thiol RSH with diethyl azodicarboxylate (EtOOCN=NCOOEt) to give an adduct, to which another thiol (R′SH) is then added, producing the disulfide (RSSR′).[841]

OS **III**, 86, 116.

19.B.ii. Reductions

For the most part, reductions have been grouped into this chapter, with a few notable exceptions. Catalytic hydrogenation of alkenes and alkynes in Reactions **15-11** and **15-12**, hydrogenation of aromatic rings in Reaction **15-13**, and reductive cleavage of cyclopropanes in Reaction **15-15** were placed in Chapter 15 to coincide with addition reactions, and protonolysis of alkyl boranes in Reaction **15-16** was placed there also for continuity. In general, reductions of functional groups encompass a variety of reaction types. The reactions in this section are classified into groups depending on the type of bond change

involved. These groups are (1) attack at carbon (C—O and C=O), (2) attack at non-carbonyl multiple bonds to heteroatoms, (3) reactions in which a heteroatom is removed from the substrate, (4) reduction with cleavage, (5) reductive coupling, and (6) reactions in which an organic substrate is both oxidized and reduced. Most of the reagents in this section are metal hydrides, metals with an acid or a protic solvent, hydrogen gas with a catalyst, and so on. Other reducing agents are available, and will be introduced in the appropriate section. Note that plants can be used as reducing agents.[842]

A. Selectivity[843]

It is often necessary to reduce one group in a molecule without affecting another reducible group (this is called chemoselectivity), and reducing agents are available that will do this. The most common broad-spectrum reducing agents are the metal hydrides[844] or hydrogen (with a catalyst).[845] Many different metal hydride systems and hydrogenation catalysts have been investigated in order to find conditions under which a given group will be reduced chemoselectively. The ease of reduction for various functional groups toward catalytic hydrogenation is acyl halides > alkyl nitro compounds > alkynes > aldehydes > alkenes > ketones > benzylic ethers > nitriles > esters > amides.[846] Futher, Table 19.2 and 19.4 list the reactivity of various functional groups with $LiAlH_4$, and BH_3, respectively.[846] Table 19.5 shows which groups can be reduced by catalytic hydrogenation and various metal hydrides.[847] Of course, the tables cannot be exact, because the nature of R and the reaction conditions obviously affect reactivity. Nevertheless, the tables do give a fairly good indication of which reagents reduce which groups.[848] Lithium aluminum hydride is very powerful and unselective reagent.[849] Other metal hydrides are generally used when chemoselectivity is required. As will be seen in Reaction **19-36**, less reactive (and more selective) reagents have been prepared by replacing some of the hydrogen atoms of $LiAlH_4$ with alkoxy groups.[850] Most of the metal hydrides are nucleophilic reagents and attack the

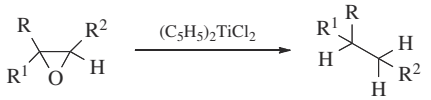
[858] Reacts with solvent, reduced in aprotic solvents.

[859] Reduced to an aldehyde (Reaction **19–44**).



B. Attack at Carbon (C—O And C=O)

19-35 Reduction of Epoxides

(3) *OC-seco*-Hydro-de-alkoxylation

Reduction of epoxides is a special case of Reaction **19-56** and is easily carried out.[860] A common reagent is $LiAlH_4$,[861] which reacts by the S_N2-type mechanism, giving inversion of configuration. An epoxide on a substituted cyclohexane ring cleaves in such a direction as to give an axial alcohol. As expected for an S_N2 mechanism, the hydrogen atom is usually delivered to the less substituted carbon. The reaction has also been carried out with other reagents (e.g., sodium amalgam in EtOH, Li in ethylenediamine,[862] and by catalytic hydrogenolysis).[863] Chemoselective and regioselective ring opening of allylic epoxides and of epoxy ketones and esters has been achieved with SmI_2,[864] HCOOH—NEt_3 and a Pd catalyst,[865] and sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al; also known as Vitride).[866] Highly hindered epoxides can be conveniently reduced, without rearrangement, with lithium triethylborohydride (called Super Hydride).[867] For certain substrates, the epoxide ring can be opened the other way by reduction with $NaBH_4$—$ZrCl_4$,[868] Pd/C and $HCOONH_4$,[869] or with BH_3 in THF.[870]

Epoxy ketones are selectively reduced with lithium naphthalenide[871] or Cp_2TiCl in THF/MeOH[872] to the β-hydroxyketone. Other reduction methods can lead to the epoxy alcohol. Reduction of epoxy amides with SmI_2 in methanol gave the α-hydroxyamide.[873]

Epi-sulfides can be reduced to give the alkene using Bu_3SnH in the presence of BEt_3.[874]

The usual product of epoxide reductions is the alcohol, but epoxides are reduced all the way to the alkane by titanocene dichloride[875] and by $Et_3SiH—BH_3$.[876]

19-36 Reduction of Aldehydes and Ketones to Alcohols[877]

C,*O*-Dihydro-addition

Aldehydes can be reduced to primary alcohols, and ketones to secondary alcohols, by a number of reducing agents.[878] Among the most common are the metal hydrides (e.g., $LiAlH_4$, $NaBH_4$, and related compounds).[879] These reagents have two main advantages over many other reducing agents: They do not reduce carbon–carbon double or triple bonds (with the exception of propargylic alcohols),[880] and with $LiAlH_4$ all four hydrogen atoms are theoretically usable for reduction. Methods are available for titering hydride reagents.[881] The scope of these reagents with ketones is similar to that with aldehydes. Lithium aluminum hydride reduces even sterically hindered ketones.

The reaction is broad and general. Lithium aluminum hydride easily reduces aliphatic, aromatic, alicyclic, and heterocyclic aldehydes or ketones, containing double or triple bonds and/or nonreducible groups (e.g., NR_3, OH, OR, and F). If the molecule contains a group reducible by $LiAlH_4$ (e.g., NO_2, CN, COOR), then that group is usually reduced. Since $LiAlH_4$ reacts readily with water and alcohols, protic solvents must be excluded. Despite limited solubility, common solvents are ether and THF.

The compound $NaBH_4$ (sodium borohydride) has a similar scope, but is less reactive, so it is more selective and so may be used with NO_2, Cl, COOR, CN, and so on in the molecule. Another advantage of $NaBH_4$ is that it can be used in water or alcoholic solvents, and so reduces compounds, (e.g., sugars) that are not soluble in ethers.[882] Other solvents can be used with some modification of the borohydride. For example, butyltriphenylphosphonium borohydride reduces aldehydes to alcohols in dichloromethane.[883] Reduction with solid acid activated $NaBH_4$ has been reported.[884] A polymer-bound phase-transfer material with $NaBH_4$ in wet THF has also been used.[885] Sodium borohydride on

alumina, under microwave irradiation, is an effective reagent.[886] Sodium borohydride has been used on silica gel.[887]

Red-Al was prepared by Vit in 1967,[888] and its reducing power is close to that of $LiAlH_4$. In addition, it is stable to dry air (it does not ignite in even moist air or oxygen), and is thermally stable up to 200 °C. The greatest practical utility of Red-Al is its solubility in aromatic hydrocarbon and ether solvents, which allows it to be conveniently used for applications that require inverse addition of hydrides. Red-Al essentially reacts the same as $LiAlH_4$, reducing aldehydes, ketones[889] and acid derivatives to alcohols.[890] Reduction of conjugated carbonyls gives primarily 1,2-reduction to an allylic alcohol.[891] Other functional groups can be reduced.[892]

The C=C units in compounds that contain double bonds are generally not affected by metallic hydrides, and the C=C unit may be isolated or conjugated, but double bonds that are conjugated with the C=O group may or may not be reduced, depending on the substrate, reagent, and reaction conditions.[893] Some reagents that reduce only the C=O bonds of α,β-unsaturated aldehydes and ketones are AlH_3,[894] $NaBH_4$, or $LiAlH_4$ in the presence of lanthanide salts,[895] Co complexes,[896] $NaBH_4$—$LiClO_4$,[897] Ni compounds,[898] $NaBH_3(OAc)$,[899] $Zn(BH_4)_2$[900] on Y-zeolite,[901] and Et_3SiH.[902] Also, both $LiAlH_4$[903] and $NaBH_4$[904] predominantly reduce only the C=O bonds of C=C—C=O systems in most cases, although substantial amounts of fully saturated alcohols have been found in some cases[903] (Reaction **15-14**). For some reagents that reduce only the C=C bonds of conjugated aldehydes and ketones, see Reaction **15-11**. A mixture of $InCl_3$ and $NaBH_4$ reduced both the C=C and C=O units of conjugated ketones.[905]

When a functional group is selectively attacked in the presence of a different functional group, the reaction is said to be *chemoselective*.[906] A number of reagents have been found to reduce aldehydes much faster than ketones. Among these[907] are sodium triacetoxyborohydride[908] ($NaBH_4$—HCO_2H),[909] zinc borohydride in THF,[910] a complex of $LiAlH_4$ and *N*-methyl-2-pyrrolidinone (of particular interest since it is stable in air and to heating),[911] and Raney nickel.[912]

Ketones can be chemoselectively reduced in the presence of aldehydes with $NaBH_4$ in aq EtOH at $-15\,^{\circ}C$ in the presence of cerium trichloride ($CeCl_3$).[913] The reagent lithium *n*-dihydropyridylaluminum hydride reduces diaryl ketones much better than dialkyl or alkyl aryl ketones.[914] Most other hydrides reduce diaryl ketones more slowly than other types of ketones. Saturated ketones can be reduced in the presence of α,β-unsaturated ketones with $NaBH_4$–50% MeOH—CH_2Cl_2 at $-78\,^{\circ}C$,[915] and with zinc borohydride.[916]

In general, $NaBH_4$ reduces carbonyl compounds in the order aldehydes > α,β-unsaturated aldehydes > ketones > α,β-unsaturated ketones, and a carbonyl group of one type can be selectively reduced in the presence of a carbonyl group of a less reactive type.[917] A number of reagents will preferentially reduce the less sterically hindered of two carbonyl compounds, but by the use of Dibal-H in the presence of the Lewis acid methylaluminum bis(2,16-di-*tert*-butyl-4-methylphenoxide), it was possible selectively to reduce the *more hindered* of a mixture of two ketones.[918] It is obvious that reagents can often be found to reduce one kind of carbonyl function in the presence of another.[919] For a discussion of selectivity in reduction reactions (see Sec. 19.B.ii-A). A syn-selective reduction of β-hydroxy ketones was achieved using $(i\text{PrO})_2TiBH_4$.[920] Quinones are reduced to hydroquinones by $LiAlH_4$, $SnCl_2$—HCl, or sodium hydrosulfite ($Na_2S_2O_4$), as well as by other reducing agents.

The reagent lithium tri-*sec*-butylborohydride [LiBH(*sec*-Bu)$_3$, L-Selectride] reduces cyclic and bicyclic ketones in a highly stereoselective manner.[921] For example, 2-methylcyclohexanone gave *cis*-2-methylcyclohexanol with an isomeric purity > 99%. Both L-Selectride and the potassium salt (K-Selectride) reduce carbonyls in cyclic and acyclic molecules with high diastereoselectivity.[922] The more usual reagents (e.g., $LiAlH_4$ and $NaBH_4$) reduce relatively

unhindered cyclic ketones either with little or no stereoselectivity[923] or give predominant formation of the more stable isomer (axial attack).[924] Reduction of cyclohexanone derivatives with the very hindered $LiAlH(Cet_2CMe_3)_3$ gave primarily the cis-alcohol.[925] Cyclohexanones that have a large degree of steric hindrance near the carbonyl group usually give predominant formation of the less stable alcohol, even with $LiAlH_4$ and $NaBH_4$.

Other reagents reduce aldehydes and ketones to alcohols,[926] including the following:

1. *Hydrogen and a Catalyst.*[927] Common heterogeneous catalysts for carbonyls are Pt and Ru,[928] and homogeneous catalysts are commonly used,[929] especially for asymmetric hydrogenation (see **A** below). Before the discovery of the metal hydrides, this was one of the most common ways of effecting this reduction, but it suffers from the fact that C=C, C≡C, C=N and C≡N bonds are often more susceptible to attack than C=O bonds.[930] For aromatic aldehydes and ketones, reduction to the hydrocarbon (Reaction **19-61**) is a side reaction via hydrogenolysis of the initially produced alcohol (Reaction **19-54**). The mechanism of catalytic hydrogenation of aldehydes and ketones is probably similar to that of reaction **15–11**.[931]
2. *Sodium in Ethanol.*[932] This is called the *Bouveault–Blanc procedure* and was more popular for the reduction of carboxylic esters (Reaction **19-38**) than of aldehydes or ketones before the discovery of $LiAlH_4$.

   For the reaction with sodium in ethanol the following mechanism[933] has been suggested:[934]

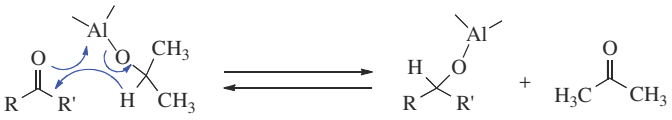
The ketyl intermediate can be isolated.[935] Lithium is often a superior metal for alkali metal reductions.[936]

3. *Other Metal Reductions*. A single carbonyl group of an α-diketone can be reduced to give an α-hydroxy ketone, by heating with Zn powder in aq DMF[937] or Zn in methanol in the presence of benzyltriethylammonium chloride.[938] Aluminum and NaOH in aq methanol reduces ketones.[939] β-Hydroxy ketones are reduced with good antiselectivity using an excess of SmI_2 in water,[940] and other ketones or aldehydes are reduced with SmI_2[941] in aq THF,[942] or in alcohols.[943] Other metals can be used, including $FeCl_3$/Zn in aq DMF[944] or Mg in alcohols.[945] 1,2-Diketones were reduced to the α-hydroxy ketone with TiI_4 in acetonitrile, followed by hydrolysis.[946] Ammonia and aq $TiCl_3$ in methanol reduces ketones.[947]
4. *Isopropyl Alcohol and Aluminum Isopropoxide*. This is called the *Meerwein–Ponndorf–Verley reduction*.[948] It is reversible, and the reverse reaction is known as the *Oppenauer oxidation* (see **19-3**):



The equilibrium is shifted by removal of the acetone by distillation. There is a report of the reduction of benzaldehyde to benzyl alcohol by heating with 2-propanol at 225 °C for 1 day.[949] The reaction usually takes place under very mild conditions and is highly specific for aldehydes and ketones, so that C=C bonds (including those conjugated with the C=O bonds) and many other functional groups can be present without themselves being reduced.[950] This includes acetals, so that one of two carbonyl groups in a molecule can be specifically reduced if the other is first converted to an acetal. β-Keto esters, β-diketones, and other ketones and aldehydes with a relatively high enol content do not give this reaction. Zeolites have been used as a medium for this reduction.[951] This reduction can be done catalytically[952] and an

aluminum-free, Zr-zeolite catalyst has been developed.[953] Microwave irradiation of a ketone with 2-propanol, KOH, and activated alumina gives good yields of the alcohol.[954] When the carbonyl substrate has a stereogenic center, the reaction proceeds with good diastereoselectivity.[955] The use of chiral metal complexes leads to chiral hydrogen transfer.[956] A combination of 2-propanol with BINOL and $AlMe_3$ leads to reduction of α-chloroketones to the chlorohydrin with good enantioselectivity.[957]

The *Meerwein–Ponndorf–Verley reaction* usually[958] involves a cyclic transition state:[959]

but in some cases 2 molar equivalents of aluminum alkoxide are involved: one attacking the carbon and the other the oxygen, a conclusion that stems from the finding that in these cases the reaction was 1.5 order in alkoxide.[960] The alcohol solvent acts as a hydrogen donor in this reaction.[961] Although, for simplicity, the alkoxide is shown as a monomer, it actually exists as trimers and tetramers, which are the actual reactive species.[962] Note that supercritical 2-propanol has been used for reduction of ketones, without the need for a catalyst.[963]

5. *Boranes*. Borane (BH_3) and substituted boranes reduce aldehydes and ketones in a manner similar to their addition to C=C bonds (Reaction **15-16**).[964] That is, the boron adds to the oxygen and the hydrogen to the carbon:[965]

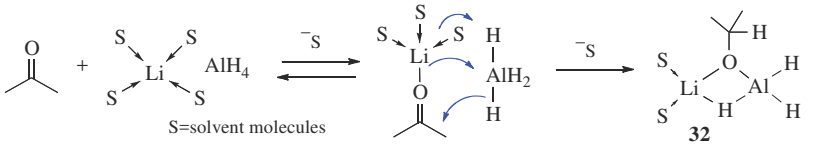
The resulting borate is then hydrolyzed to the alcohol. A variety of alkylboranes can be used for reduction.[966] Both 9-BBN[967] (Reaction **15-16**) and BH_3—Me_2S[968] reduce only the C=O group of conjugated aldehydes and ketones.[969] Tributylborane in ionic solvents reduces aldehydes to alcohols.[970] Enantioselective borane reductions lead to chiral alcohols.[971] Spiroborate esters have been used for enantioselective reduction,[972] and chiral boronic esters have also been used.[973]

Alane (AlH_3) derivatives can also be used, including diisobutylaluminum hydride.[974]



6. *Tin Hydrides*. Tributyltin hydride reduces aldehydes to primary alcohols by simply heating in methanol.[975] A mixture of Bu_3SnH and phenylboronic acid (Reaction **12-28**) reduces aldehydes in dichloromethane.[976] Reduction of ketones was achieved with Bu_2SnH_2 and a Pd catalyst.[977] Using triaryltin hydrides with $BF_3{\cdot}OEt_2$, where aryl is 2,6-diphenylbenzyl, selective reduction of aliphatic aldehydes in the presence of a conjugated aldehyde was achieved.[978] Tris(trimethylsilyl)methane has been used as a tin-free radical reducing agent.[979]
7. *Cannizzaro Reaction*. In the Cannizzaro reaction (see **19-81**), aldehydes without an α hydrogen are reduced to alcohols.
8. *Silanes*. In the presence of bases, certain silanes can selectively reduce carbonyls.[980] Transition metal complexes also catalyze hydrosilylation of ketones.[981] Controlling temperature and solvent leads to different ratios of *syn* and *anti* products.[982] Silanes reduce ketones in the presence of $BF_3{\cdot}OEt_2$.[983] Ketones are reduced with Cl_3SiH in the presence of pyrrolidine carbaldehyde[984] or under

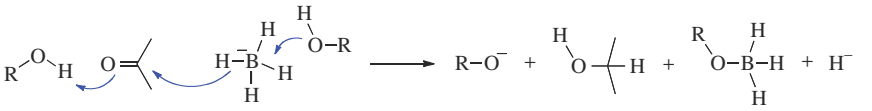
photochemical conditions.[985] Polymethylhydrosiloxane with tetrabutylammonium fluoride reduces α-amino ketones to give the syn amino alcohol.[986]



9. *Ammonium Formates*. Sodium formate and trialkylammonium formates can be used to reduce aldehydes and ketones to the corresponding alcohol. Decanal was reduced to decanol, for example, using sodium formate in *N*-methyl-2-pyrrolidinone as a solvent.[987] A mixture of formic acid and ethyl magnesium bromide was used to reduce decanal to decanol in 70% yield.[988] Transfer hydrogenation also occurs with formic acid–triethylamine and a Ru catalyst[989] in water.[990]
10. *Enzymatic Reductions*. Successful asymmetric reductions (see Section A) have been achieved with biologically derived reducing agents[991] (e.g., baker's yeast),[992] enzymes from other organisms,[993] or with other biocatalysts.[994] Ionic liquids have been used in conjugation with enzymatic reduction,[995] and enzymatic reduction has been done in supercritical CO_2.[996]

With most reagents there is an initial attack on the carbon of the carbonyl group by a hydride equivalent (H^-) although with BH_3[997] the initial attack is on the oxygen. Detailed mechanisms are not known in most cases.[998] With $LiAlH_4$ or $NaBH_4$, the attacking species is the AlH_4^- (or BH_4^-) ion, which, in effect, transfers H^- to the carbon. The following mechanism has been proposed for $LiAlH_4$:[999]

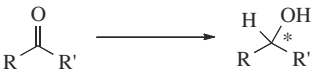
Evidence that the cation plays an essential role, at least in some cases, is that when the Li^+ was effectively removed from $LiAlH_4$ (by the addition of a crown ether), the reaction did not take place.[1000] Complex **32** must be hydrolyzed to the alcohol. For $NaBH_4$, the Na^+ does not seem to participate in the transition state, but kinetic evidence shows that an OR group from the solvent does participate and remains attached to B:[1001]

Free H^- cannot be the attacking entity in most reductions with boron or aluminum hydrides because the reactions are frequently sensitive to the size of the MH_4^- [or $MR_mH_n^-$ or $M(OR)_mH_n^-$ etc.].



The question of whether the initial complex in the $LiAlH_4$ reduction (**32**, or H—C—OAl^-H_3 = **33**) can reduce another carbonyl to give $(H—C—O)_2Al^-H_2$, and so on has been controversial. It has been shown[1002] that this is probably not the case but that, more likely, **33** disproportionates to $(H—C—O)_4Al^-$ and AlH_4^-, which is the only attacking species. Disproportionation has also been reported in the $NaBH_4$ reaction.[1003]

Aluminate (**33**) is essentially $LiAlH_4$ with one of the hydrogen atoms replaced by an alkoxy group (i.e., $LiAlH_3OR$). The fact that **33** and other alkoxy derivatives of $LiAlH_4$ are less reactive than $LiAlH_4$ itself has led to the use of such compounds as reducing agents that are less reactive and more selective than $LiAlH_4$.[1004] An example is $LiAlH(O\text{-}t\text{-}Bu)_3$ (Reactions **19-39**–**19-41**; see also, Table 19.5). As an example of chemoselectivity in this reaction it may be mentioned that $LiAlH(Ot\text{-}Bu)_3$ has been used to reduce only the keto group in a molecule containing both keto and carboxylic ester groups.[1005] However, the use of such reagents is sometimes complicated by the disproportionation mentioned above, which may cause $LiAlH_4$ to be the active species, even if the reagent is an alkoxy derivative. Another highly selective reagent (reducing aldehydes and ketones, but not other functional groups), which does not disproportionate, is potassium triisopropoxyborohydride.[1006]

For other reduction reactions of aldehydes and ketones, see **19-61**, **19-76**, and **19-81**.

A. Asymmetric Reduction

Unsymmetrical ketones are prochiral (Sec. 4.M); that is, reduction creates a new stereogenic center:

The relative effectiveness of various reagents for reduction of eight other types of ketone was determined, using several different reducing agents.[1007] The ketones examined included heterocyclic, aralkyl, β-keto esters, β-keto acids,[1008] and so on.[991] Much effort has been put into finding optically active reducing agents that will produce one enantiomer of the alcohol enantioselectively.[1009] Each reagent tends to show a specificity for certain types of ketones.[1010] Good enantioselectivity is usually obtained with the proper reagent.[1011] Substituents that are remote to the carbonyl group can play a role in facial selectivity of the reduction.[1012] Asymmetric reduction has been accomplished using bioreagents (e.g., enzymes, see item 10 above).

Asymmetric reduction with very high enantioselectivity has also been achieved with achiral reducing agents and optically active catalysts.[1013] Homogeneous catalytic asymmetric hydrogenation leads to reduction of substrates with high enantioselectivity.[1014] A typical chiral ligand is 2,2′-bis(diphenylphosphino)-1,1′-binaphthylruthenium acetate (BINAP, **34**), used with a metal catalysts [e.g., $Ru(OAc)_2$],[1015] β-Keto esters are reduced enantioselectively, for example.[1016] A variety of chiral additives and/or ligands have been used with catalytic hydrogenation reactions. Many functional groups can be tolerated.[1017] Asymmetric catalytic hydrogenation has been done in ionic liquids.[1018]

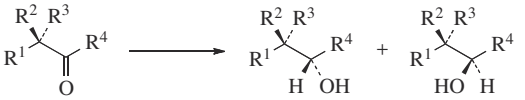
(*R*)-(+)-BINAP

35

A second approach is reduction with BH_3—THF or catecholborane,[1019] using an oxazaborolidine (**35**, R = H, Me, or *n*-Bu; Ar = Ph or β-naphthyl)[1020] or other chiral compounds[1021] as a catalyst. Both a polymer-bound oxazaborolidine[1022] and a dendritic chiral catalyst have been used in conjunction with borane,[1023] as well as other chiral additives can be used.[1024] Chiral sulfonamides have been used as additives.[1025]

Lithium aluminum hydride in combination with a chiral diol[1026] or other chiral ligands[1027] leads to enantioselective reduction, often in the presence of a transition metal complex.[1028] Chiral additives have also been used with $NaBH_4$.[1029] Examples include $LiBH_4/NiCl_2$ and a chiral amino alcohol,[1030] $NaBH_4$ with chiral Lewis acid complexes,[1031] or $NaBH_4/Me_3SiCl$ and a chiral ligand.[1032] A mixture of $NaBH_4$ and Me_3SiCl with a catalytic amount of a chiral, polymer-bound sulfonamide leads to asymmetric reduction.[1033]



Enantioselective reduction is possible with the other methods mentioned above. Transition metal catalyzed asymmetric transfer hydrogenation is effective for the

preparation of chiral alcohols.[1034] Reduction with silanes and transition metal catalysts (e.g., Ru compounds) is also very effective.[1035] Chiral Ru catalysts have been used with triethylammonium formate for the enantioselective reduction.[1036] The transition metal catalyzed hydrosilylation of ketones gives chiral alcohols in the presence of suitable chiral ligands.[1037] Enantioselective reduction was observed with $PhSiH_3$ and Cu compounds with a chiral ligand,[1038] with a mixture of Ru and Ag catalysts,[1039] or with $Mn(dpm)_3$ and oxygen (dpm = diphenylmethylene).[1040] Enantioselective hydrosilylation is possible using chiral organocatalysts.[1041] A chiral Sm complex has been used in conjunction with 2-propanol.[1042] Chiral mercapto alcohols have also been used for asymmetric reduction.[1043]

Enantioselective reduction is usually not possible for aldehydes,[1044] since the products are primary alcohols in which the reduced carbon is not chiral. Instead deuterated aldehydes (RCDO) give a chiral product, and these have been reduced enantioselectively with B-(3-pinanyl)-9-borabicyclo[3.3.1]nonane (Alpine-Borane) with almost complete optical purity.[1045] Other chiral boranes can be used to reduce aldehydes or ketones.[1046]

In the above cases, an optically active reducing agent or catalyst interacts with a prochiral substrate. Asymmetric reduction of ketones has also been achieved with an achiral reducing agent, if the ketone is complexed to an optically active transition metal Lewis acid.[1047]

There are other stereochemical aspects to the reduction of aldehydes and ketones. If there is a stereogenic center α to the carbonyl group,[1048] even an achiral reducing agent can give more of one diastereomer than of the other (a diastereoselective reduction). Such reductions have been carried out with considerable success.[1049] In most such cases, *Cram's rule* (Sec. 4.H., category 1) is followed, but exceptions are known.[1050]

19-37 Reduction of Carboxylic Acids to Alcohols

Dihydro-de-oxo-bisubstitution

$$RCOOH \xrightarrow{LiAlH_4} RCH_2OH$$

Carboxylic acids are easily reduced to primary alcohols by $LiAlH_4$.[1051] The conditions are particularly mild, the reduction proceeding quite well at room temperature. Other hydrides have also been used,[1052] but not $NaBH_4$ (see Table 19.5).[1053] A combination of $NaBH_4$ and an arylboronic acid (Reaction **12-28**) is also effective.[1054] A mixture of $NaBH_4$, Me_2SO_4, and $B(OMe)_3$ is effective for the reduction of hydroxyl-substituted aromatic carboxylic acids.[1055] Benzyltriethylammonium borohydride is dichloromethane reduces carboxylic acids to the alcohol.[1056] Catalytic hydrogenation is generally ineffective.[1057]

Borane (BH_3) is particularly good for carboxyl groups (Table 19.4) and permits selective reduction of them in the presence of many other groups (although the reaction with double bonds takes place at about the same rate in ether solvents).[1058] For many years, borane was the reagent of choice for this reduction. Borane also reduces carboxylic acid salts.[1059] Aluminum hydride reduces COOH groups without affecting carbon–halogen bonds in the same molecule. The reduction has also been carried out with SmI_2 in basic media[1060] or aq H_3PO_4,[1061] or simply with SmI_2 in water.[1062] A mixture of $NaBH_4$ and I_2 has been used to reduced amino acids to amino alcohols.[1063]

19-38 Reduction of Carboxylic Esters to Alcohols

Dihydro,hydroxy-de-oxo,alkoxy-tersubstitution

$$RCOOR' \xrightarrow{LiAlH_4} RCH_2OH + R'OH$$

Lithium aluminum hydride reduces carboxylic esters to give two different alcohols, as shown.[1064] The reaction is of wide scope and has been used to reduce many esters. Where the interest is in obtaining R′OH, this is a method that is often a working equivalent of "hydrolyzing" esters. Reduction of lactones yields diols.[1065] Among the reagents used for this reduction[1066] are Dibal-H, lithium triethylborohydride, $LiAlH(O\textit{t}\text{-}Bu)_3$,[1067] and $BH_3—SMe_2$ in refluxing THF.[1068] Although $NaBH_4$ reduces phenolic esters, especially those containing electron-withdrawing groups,[1069] its reaction with other esters is usually so slow that it is not the reagent of choice, but there are many exceptions.[1070]) However, it is generally possible to reduce an aldehyde or ketone without reducing an ester function in the same molecule. Note that $NaBH_4$ reduces esters in the presence of certain compounds (see Table 19.5).[1071] Note that $NaBH_4$ in DMF—MeOH reduces aryl carboxylic esters to benzylic alcohols,[1072] and $NaBH_4$—LiCl with microwave irradiation also reduces esters to primary alcohols.[1073]

Carboxylic esters can also be reduced to alcohols by hydrogenation over copper chromite catalysts,[1074] although high pressures and temperatures are required. Ester functions generally survive low-pressure catalytic hydrogenations, but homogeneous catalytic hydrogenation procedures have been developed.[1075] Before the discovery of $LiAlH_4$, the most common way of carrying out the reaction was with sodium in ethanol, a method known as the *Bouveault–Blanc procedure*.[1076] This procedure is still sometimes used where selectivity is necessary (see also, Reactions **19-62**, **19-65**, and **19-59**).

Silanes (e.g., Ph_2SiH_2), with a catalytic amount of triphenylphosphine and a Rh catalyst reduced esters to primary alcohols.[1077] Aliphatic silanes (e.g., $EtMe_2SiH$) also reduced esters with a Ru catalyst.[1078]

19-39 Reduction of Acyl Halides

Hydro-de-halogenation or Dehalogenation

$$\text{RCOCl} \xrightarrow[-78^\circ\text{C}]{\text{LiAlH(O}t\text{-Bu)}_3} \text{RCHO}$$

Acyl halides can be reduced to aldehydes[1079] by treatment with lithium tri-*tert*-butoxyaluminum hydride in diglyme at −78 °C.[1080] The R group may be alkyl or aryl and may contain many types of substituents, including NO_2, CN, and EtOOC groups. The reaction stops at the aldehyde stage because steric hindrance prevents further reduction with this reagent. Acyl halides can also be reduced to aldehydes by hydrogenolysis with Pd on barium sulfate as catalyst in what is called the *Rosenmund reduction*.[1081] A convenient hydrogenolysis procedure involves Pd on charcoal as the catalyst, with ethyldiisopropylamine as acceptor of the liberated HCl and acetone as the solvent.[1082] The reduction of acyl halides to aldehydes has also been carried out[1083] with Bu_3SnH,[1084] an $InCl_3$ catalyzed reaction using Bu_3SnH,[1085] $NaBH_4$ in a mixture of DMF and THF,[1086] with Sm—PBu_3,[1087] and with formic acid/NH_4OH.[1088] Polymethylhydrosiloxane (PMHS) reduces acid chlorides to aldehydes in the presence of a Pd catalyst.[1089] In some of these cases, the mechanisms are free radical.

There are several indirect methods for the conversion of acyl halides to aldehydes, most of them involving prior conversion of the halides to certain types of amides (see Reaction **19-41**). There is also a method in which the COOH group is replaced by a completely different CHO group (Reaction **16-87**).

19-40 Reduction of Carboxylic Acids, Esters, and Anhydrides to Aldehydes[1090]

Hydro-de-hydroxylation or Dehydroxylation (overall transformation)

$$\text{RCOOH} \longrightarrow \text{RCHO} \longleftarrow \text{RCOOR}'$$

With most reducing agents, reduction of carboxylic acids generally gives the primary alcohol (Reaction **19-37**) and the isolation of aldehydes is not feasible. However, simple straight-chain carboxylic acids have been reduced to aldehydes[1091] by treatment with Li in $MeNH_2$ or NH_3 followed by hydrolysis of the resulting imine,[1092] with

$$\text{RCOOH} \xrightarrow[\text{MeNH}_2]{\text{Li}} \text{RCH=N—Me} \xrightarrow{\text{H}_2\text{O}} \text{RCHO}$$

with thexylchloro(or bromo)borane–SMe_2[1093] (see Reaction **15-16** for the thexyl group), $Me_2N{=}CHCl^+\ Cl^-$ in pyridine,[1094] and with diaminoaluminum hydrides.[1095] Benzoic acid derivatives were reduced to benzaldehyde derivatives with NaH_2PO_2 and a diacylperoxide and Pd catalyst.[1096] Caproic and isovaleric acids have been reduced to aldehydes in 50% yields or better with Dibal-H (*i*-Bu_2AlH) at -75 to $-70\,^\circ C$.[1097]

Carboxylic esters have been reduced to aldehydes with Dibal-H at $-70\,^\circ C$, with diaminoaluminum hydrides,[1098] and for phenolic esters with $LiAlH(O\textit{t}\text{-Bu})_3$ at $0\,^\circ C$.[1099] Pretreatment of the acid with Me_3SiCl followed by reduction with Dibal-H also gives the aldehyde.[1100] Aldehydes have also been prepared by reducing ethyl thiol esters (RCOSEt) with Et_3SiH and a Pd—C catalyst.[1101] Thioesters have been reduced to the aldehyde with Li metal in THF at $-78\,^\circ C$, followed by quenching with methanol.[1102]

Anhydrides, both aliphatic and aromatic, as well as mixed anhydrides of carboxylic and carbonic acids, have been reduced to aldehydes in moderate yields with disodium tetracarbonylferrate [$Na_2Fe(CO)_4$].[1103] Heating a carboxylic acid, presumably to form the anhydride, and then reaction with Na/EtOH leads to the aldehyde.[1104]

Acid chlorides are reduced to aldehydes with Bu_3SnH and a Ni catalyst.[1105]

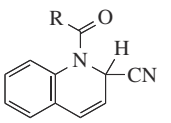
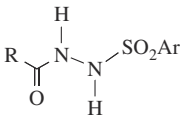
19-41 Reduction of Amides to Aldehydes



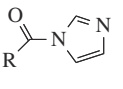
Hydro-de-dialkylamino-substitution

$$RCONR_2' + LiAlH_4 \longrightarrow RCHO + NHR_2'$$

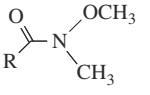


N,N-Disubstituted amides can be reduced to amines with $LiAlH_4$ (see Reaction **19-64**), but reduction to an aldehyde is possible.[1106] Keeping the amide in excess gives the aldehyde rather than the amine. Sometimes it is not possible to prevent further reduction and primary alcohols are obtained instead. Other reagents[1107] that give good yields of aldehydes are Dibal-H,[1108] $LiAlH(Ot\text{-}Bu)_3$, diaminoaluminum hydrides,[1109] disiamylborane (see Reaction **15-16** for the disiamyl group),[1110] and $Cp_2Zr(H)Cl$.[1111]

Aldehydes have been prepared from carboxylic acids or acyl halides by first converting them to certain types of amides that are easily reducible. There are several examples:[1112]



1. *Reissert Compounds.*[1113] Compounds, such as **36,** are prepared from the acyl halide by treatment with quinoline and cyanide ion. Treatment of **36** with sulfuric acid gives the corresponding aldehyde.



36

37

38

39

2. *Acyl Sulfonylhydrazides.* Compounds, such as **37**, are cleaved with base to give aldehydes. This reaction is known as the *McFadyen–Stevens reduction* and is applicable *only* to aromatic aldehydes or aliphatic aldehydes with no α hydrogen.[1114] Acyl imide (RCON=NH, see reaction **19-67**) has been proposed as an intermediate in this reaction.[1115]
3. *Acyl Imidazoles.* Compounds **38**[1116] can be reduced to aldehydes with $LiAlH_4$.

C. Attack at Non-Carbonyl Multiple Bonded Heteroatoms

19-42 Reduction of the Carbon–Nitrogen Double Bond (C=N)

C,*N*-Dihydro-addition

Imines and *Schiff bases*,[1119] hydrazones,[1120] and other C=N compounds can be reduced with $LiAlH_4$, $NaBH_4$,[1121] Na—EtOH, hydrogen and a catalyst, as well as with other reducing agents.[1122] Metal-free catalytic hydrogenation is known.[1123] Transfer hydrogenation of imines leads to amines.[1124] A mixture of Sm/I_2[1125] or In/NH_4Cl[1126] also reduces imines. Reduction with Bu_2SnClH in HMPA has been shown to be chemoselective for imines.[1127] Iminium salts are reduced by $LiAlH_4$ to the corresponding amine, although here there is no "addition" to the nitrogen:[1128] Silanes[1129] with a triarylborane catalyst reduces *N*-sulfonyl imines[1130] as does TiI_4.[1131] Imines are reduced with samarium bromide in HMPA,[1132] 2-propanol with a Ru catalyst,[1133] and with triethylammonium formate with microwave irradiation.[1134] Oximes are reduced with hydrogen gas and a catalytic amount of 48% HBr.[1135]

Oximes are generally reduced to amines (Reaction **19-48**),[1136] but simple reduction to give hydroxylamines can be accomplished with borane[1137] or sodium cyanoborohydride.[1138] Oxime *O*-ethers are reduced with Bu_3SnH and $BF_3{\cdot}OEt_2$.[1139] Diazo compounds (ArN=NAr) are reductively cleaved to aniline derivatives with Zn and ammonium formate in methanol.[1140]

Reduction of imines has been carried out enantioselectively.[1141] Catalytic hydrogenation[1142] with a chiral Ir[1143] Re,[1144] Rh,[1145] or Pd[1146] catalyst is effective. Catalytic hydrogenation of iminium salts with a chiral Ru catalyst gives the amine.[1147] Enantioselective reduction of imines is possible using a mixture of *Escherichia coli* whole cells and $H_3N{\cdot}BH_3$.[1148] *Hantzsch ester* (see Reactions **15-14** and **16-17**) reduction of imine-esters, in the presence of a chiral phosphoric acid derivative, leads to chiral amino esters.[1149] In a related reaction, enamines were reduced by hydrogenation over a chiral Rh catalyst.[1150]

Hydrogenation of oximes with Pd/C and a Ni complex gives the imine, and in the presence of a lipase and ethyl acetate the final product was an acetamide, formed with high enantioselectivity.[1151] Catalytic-transfer hydrogenation of imines leads with a chiral catalyst to chiral amines.[1152] Conjugated *N*-sulfonyl imines are reduced to the conjugated sulfonamide with good enantioselectivity using a chiral rhodium catalyst in the presence of LiF and $PhSnMe_3$.[1153] Phosphinyl imines, $R_2C{=}N{-}P(=O)Ar_2$, are reduced with high enantioselectivity using a chiral Cu catalyst.[1154] Silanes (e.g., $PhSiH_3$) can be used for the reduction of imines, and in the presence of a chiral Ti catalyst the resulting amine was formed with excellent enantioselectivity.[1155] The enantioselective reduction of aromatic imines is possible using trichlorosilane.[1156] Enzymatic reduction of imines leads to chiral amines.[1157]

19-43 The Reduction of Nitriles to Amines

***CC*,*NN*-Tetrahydro-biaddition**

$$R{-}C{\equiv}N + LiAlH_4 \longrightarrow R{-}CH_2{-}NH_2$$

Nitriles can be reduced to primary amines with many reducing agents,[1161] including $LiAlH_4$, and $BH_3{\cdot}SMe_2$.[1162] The reagent $NaBH_4$ does not generally reduce nitriles except in alcoholic solvents with a catalyst (e.g., $CoCl_2$,[1163] $NiCl_2$,[1164] or Raney nickel).[1165] Lithium dimethylaminoborohydride ($LiBH_3NMe_2$) reduces aryl nitriles to the corresponding benzylamines.[1166]

The reduction of nitriles is of wide scope and has been applied to many nitriles. Catalytic hydrogenation converts nitriles to primary amines,[1167] but secondary amines [$(RCH_2)_2NH$] are often side products.[1168] These can be avoided by adding a compound (e.g., acetic anhydride), which removes the primary amine as soon as it is formed,[1169] or by the use of excess ammonia to drive the equilibria backward.[1170] Sponge nickel[1171] or nickel on silica gel[1172] have been used for the catalytic hydrogenation of aryl nitriles to amines.

Attempts to stop with the addition with only 1 equiv of hydrogen, have failed; that is, to convert the nitrile to an imine, except where the imine is subsequently hydrolyzed (Reaction **19-44**).

N-Alkylnitrilium ions are reduced to secondary amines by $NaBH_4$.[1173]

$$RCN \xrightarrow{R'_3O^+BF_4^-} R{-}C{\equiv}\overset{+}{N}{-}R' \xrightarrow[\text{diglyme}]{NaBH_4} RCH_2{-}NH{-}R'$$

Since nitrilium salts can be prepared by treatment of nitriles with trialkyloxonium salts (see Reaction **16-8**), this is a method for the conversion of nitriles to secondary amines.

Note that the related compounds, the isonitriles ($R{-}N^+{\equiv}CO^-$, also called isocyanides) have been reduced to *N*-methylamines with $LiAlH_4$, as well as with other reducing agents.

OS **III**, 229, 358, 720; **VI**, 223.

19-44 The Reduction of Nitriles to Aldehydes

Hydro,oxy-de-nitrilo-tersubstitution

$$R{-}C{\equiv}N \xrightarrow[\text{2. hydrolysis}]{\text{1. HCl, } SnSl_2} RCH{=}O \qquad \underset{\mathbf{40}}{RCCl{=}\overset{+}{N}H_2Cl^-}$$

There are two principal methods for the reduction of nitriles to aldehydes.[1174] In one of these, known as the *Stephen reduction*, the nitrile is treated with HCl to form an iminium salt (**40**). Subsequent reduction of (**40**) with anhydrous $SnCl_2$ gives RCH=NH, which precipitates as a complex with $SnCl_4$ and is then hydrolyzed (Reaction **16-2**) to the aldehyde. The *Stephen reduction* is most successful when R is aromatic, but it can be done for aliphatic R up to about six carbons.[1175] It is also possible to prepare **40** in a different way, by treating ArCONHPh with PCl_5, which can then be converted to the aldehyde. This is known as the *Sonn–Müller method*. Aqueous formic acid in the presence of PtO_2, followed by treatment with aqueous acid converts aryl nitriles to aryl aldehydes.[1176]

The other way of reducing nitriles to aldehydes involves using a metal hydride reducing agent to add 1 molar equivalent of hydrogen and subsequent hydrolysis, *in situ*, of the resulting imine (which is undoubtedly coordinated to the metal). This reaction has been carried out with $LiAlH_4$, $LiAlH(OEt)_3$,[1177] $LiAlH(NR_2)_3$,[1178] and Dibal-H.[1179] The metal hydride method is useful for aliphatic and aromatic nitriles.

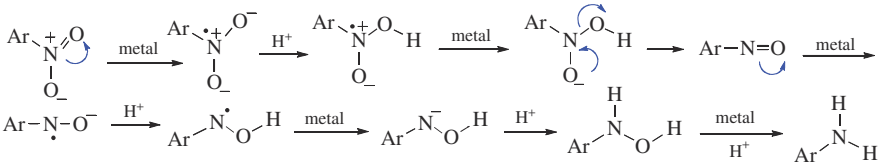
19-45 Reduction of Nitro Compounds to Amines

$$RNO_2 \xrightarrow[HCl]{Zn} RNH_2$$



Both aliphatic[1180] and aromatic nitro compounds can be reduced to amines, although the reaction has been applied much more often to aromatic nitro compounds, owing to their greater availability. Many reducing agents have been used to reduce aromatic nitro compounds, the most common being Zn, Sn, or Fe (or sometimes other metals) and acid, and catalytic hydrogenation.[1181] Chemoselective catalytic hydrogenation of nitro compounds is possible.[1182] Transfer hydrogenation is used to reduce nitro compounds.[1183] Indium metal in aq ethanol with ammonium chloride[1184] or with water in aq THF[1185] also reduces aromatic nitro compounds to the corresponding aniline derivative. Indium metal in methanol, with acetic anhydride and acetic acid, converts aromatic nitro compounds to the acetanilide.[1186] Both samarium metal in methanol with ultrasound,[1187] and a mixture of SmI_2–water and an amine reduce nitro compounds.[1188] Alternative reduction methods use ultrasound with Al(Hg) in aq THF[1189] or with stannous chloride in an ionic liquid.[1190] Some other reagents used[1191] were $Et_3SiH/RhCl(PPh)_3$,[1192] $AlH_3—AlCl_3$, formic acid and Pd—C,[1193] or formic acid with Raney nickel in methanol.[1194] The reaction with sulfides or polysulfides is called the *Zinin reduction*.[1195] Amines are also the products when nitro compounds, both alkyl and aryl, are reduced with $HCOONH_4$—Pd—C.[1196] Many other functional groups (e.g., COOH, COOR, CN, amide) are not affected by this reagent (although ketones are reduced, see Reaction **19-33**). With optically active alkyl substrates this method gives retention of configuration.[1197]

Lithium aluminum hydride reduces aliphatic nitro compounds to amines, but with aromatic nitro compounds the products with this reagent are azo compounds (Reaction **19-80**). Most metal hydrides, including $NaBH_4$ and BH_3, do not reduce nitro groups at all, although both aliphatic and aromatic nitro compounds have been reduced to amines with $NaBH_4$ and various catalysts (e.g., $NiCl_2$ or $CoCl_2$[1198] and $ZrCl_4$).[1199] Borohydride exchange resin (BER) in the presence of $Ni(OAc)_2$, however, gives the amine.[1200] Treatment of aromatic nitro compounds with $NaBH_4$ alone has resulted in reduction of the *ring* to a cyclohexane ring with the nitro group still intact[1201] or in cleavage of the nitro group from the ring.[1202] With $(NH_4)_2S$ or other sulfides or polysulfides it is often possible to reduce just one of two or three nitro groups on an aromatic ring or on two different rings in one molecule.[1203] Bakers yeast reduces aromatic nitro compounds to aniline derivatives.[1204] A combination of $NaH_2PO_2/FeSO_4$ with microwave irradiation reduces aromatic nitro compounds to aniline derivatives.[1205] Hydrazine on alumina, with $FeCl_3$ and microwave irradiation, accomplishes this reduction.[1206] Hydrazine–formic acid with Raney nickel in methanol reduces aromatic nitro compounds.[1207] Heating aromatic nitro compounds with 57% HI reduces the nitro group to the amino group.[1208]

With some reducing agents, especially with aromatic nitro compounds, the reduction can be stopped at an intermediate stage, and hydroxylamines (Reaction **19-46**), hydrazobenzenes, azobenzenes (Reaction **19-80**), and azoxybenzenes (Reaction **19-79**) can be obtained in this manner. However, nitroso compounds, which are often postulated as intermediates, are too reactive to be isolated, if indeed they are intermediates. Reduction by metals in mineral acids cannot be stopped, but always produces the amine.

The mechanisms of these reductions have not been much studied, although it is usually presumed that, at least with some reducing agents, nitroso compounds and hydroxylamines are intermediates. Both of these types of compounds give amines when exposed to most of these reducing agents (Reaction **19-47**), and hydroxylamines can be isolated (Reaction **19-46**). With metals and acid the following path has been suggested[1209]:

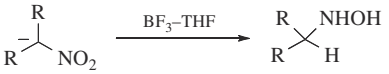
Certain aromatic nitroso compounds (Ar—NO) can be obtained in good yields by irradiation of the corresponding nitro compounds in 0.1 M aq KCN with UV light.[1210] The reaction has also been performed electrochemically.[1211] When nitro compounds are treated with most reducing agents, nitroso compounds are either not formed or react further under the reaction conditions and cannot be isolated.



Reductive alkylation of aromatic nitro compounds is possible. The reaction of nitrobenzene with allylic or benzyl halides in the presence of an excess of tin metal in methanol, leads to the *N,N*-diallyl or dibenzyl aniline.[1212] A similar reaction occurs with nitrobenzene, allyl bromide, and In metal in aq acetonitrile.[1213]

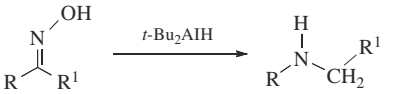
N-Hydro-de-hydroxylation or *N*-Dehydroxylation

$$RNHOH \xrightarrow[HCl]{Zn} RNH_2$$

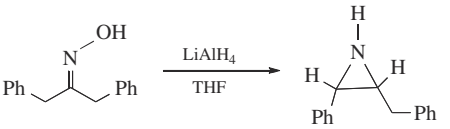
Nitroso compounds and hydroxylamines can be reduced to amines by the same reagents that reduce nitro compounds (Reaction **19-45**). Reaction with CuCl, and then phenylboronic acid (Reaction **12-28**), also reduces nitroso compounds to the amine.[1220] A hydroxylamine can be reduced to the amine with CS_2 in acetonitrile.[1221] Indium metal in EtOH/aq NH_4Cl reduces hydroxylamines to the amine.[1222] *N*-Nitroso compounds are similarly reduced to hydrazines ($R_2N—NO \rightarrow R_2N—NH_2$).[1223]

OS **I**, 511; **II**, 33, 202, 211, 418; **III**, 91; **IV**, 247. See also, OS **VIII**, 93.

19-48 Reduction of Oximes to Primary Amines or Aziridines



Both aldoximes and ketoximes can be reduced to primary amines with $LiAlH_4$. The reaction is slower than similar reduction of ketones, so that, for example, PhCOCH=NOH gave 34% PhCHOHCH=NOH.[1224] Among other reducing agents that give this reduction[1225] are zinc and acetic acid, BH_3,[1226] $NaBH_3CN—TiCl_3$,[1227] PMHS with Pd-C,[1228] and sodium and an alcohol.[1229] Catalytic hydrogenation is also effective.[1230] Reduction of oximes with In metal in acetic anhydride/acetic acid–THF leads to the acetamide.[1231]



The reduction has been performed enantioselectively with Baker's yeast[1232] and with Ph_2SiH_2 and an optically active Rh complex catalyst.[1233] Oxime *O*-ethers are reduced to the amine with modest enantioselectivity using a chiral boron compound.[1234]

When the reducing agent is Dibal-H, the product is a secondary amine, arising from a rearrangement[1235]:

With certain oximes (e.g., those of the type $ArCH_2CR{=}NOH$), treatment with $LiAlH_4$ gives aziridines,[1236] for example,

Hydrazones, arylhydrazones, and semicarbazones can also be reduced to amines with various reducing agents, including Zn—HCl and H_2 and Raney nickel.

Oximes have been reduced in a different way, to give imines ($RR'C{=}NOH \rightarrow RR'C{=}NH$), which are generally unstable, but which can be trapped to give useful products. Among reagents used for this purpose have been Bu_3P–SPh_2[1237] and $Ru_3(CO)_{12}$.[1238] Oximes can also be reduced to hydroxylamines (Reaction **19-42**). Nitrones have been reduced to imines using $AlCl_3{\cdot}6\ H_2O$/KI followed by $Na_2S_2O_3$—H_2O.[1239].

OS **II**, 318; **III**, 513; **V**, 32, 83, 373, 376.

19-49 Reduction of Aliphatic Nitro Compounds to Oximes or Nitriles

$$RCH_2NO_2 \xrightarrow[HOAc]{Zn} RCH{=}NOH$$

Nitro compounds that contain an α hydrogen can be reduced to oximes with zinc dust in acetic acid[1240] or with other reagents, among them CS_2—NEt_3,[1241] $CrCl_2$,[1242] and (for α-nitro sulfones) $NaNO_2$.[1243] α-Nitro alkenes have been converted to oximes (—C=C—$NO_2 \rightarrow$ —CH—C=NOH) with sodium hypophosphite, In with aq. NH_4Cl/MeOH,[1244] and with Pb—HOAc—DMF, as well as with certain other reagents.[1245]

$$RCH_2NO_2 \xrightarrow{NaBH_2S_3} RC{\equiv}N$$

Primary aliphatic nitro compounds can be reduced to aliphatic nitriles with *t*-BuN≡C/BuN=C=O.[1246] Secondary compounds give mostly ketones (e.g., nitrocyclohexane gave 45% cyclohexanone, 30% cyclohexanone oxime, and 19% *N*-cyclohexylhydroxylamine). Tertiary aliphatic nitro compounds do not react with this reagent (see also, Reaction **19-45**).

OS **IV**, 932.

19-50 Reduction of Azides to Primary Amines

N-Dihydro-de-diazo-bisubstitution

$$RN_3 \xrightarrow{LiAlH_4} RNH_2$$

Azides are easily reduced to primary amines by $LiAlH_4$, as well as by a number of other reducing agents,[1247] including $NaBH_4$, $NaBH_4/LiCl$,[1248] $NaBH_4/CoCl_2/H_2O$,[1249] $NaBH_4/ZrCl_4$,[1250] H_2 and a catalyst, Mg or Ca in MeOH,[1251] $Sm/NiCl_2$,[1252] Sm/I_2,[1253] $CeCl_3$,[1254] Zn/NH_4Cl/aq EtOH,[1255] baker's yeast,[1256] and In metal in EtOH.[1257] Triethylsilane has been used for the radical reduction of azides to amines.[1258]

Reaction with PPh_3 leads to a phosphazide ($Ph_3P{=}N{-}N{=}N{-}R$), which loses nitrogen in what is called the *Staudinger reaction*[1259]: a method to prepare phosphazo compounds, but in this case leads to reduction. Alkylation is possible, and the reaction of an alkyl azide with PMe_3, and then an excess of iodomethane, leads to the *N*-methylated amine.[1260] The reaction is diastereoselective.[1261] Chiral *N*-heterocyclic carbenes catalyze the *Staudinger reaction* of ketenes with imines to form β-lactam derivatives.[1262] This reaction, combined with RX → RN_3 (**10-43**), is an important way of converting alkyl halides (RX) to primary amines (RNH_2); in some cases the two procedures have been

combined into one laboratory step.[1263] Sulfonyl azides (RSO_2N_3) have been reduced to sulfonamides (RSO_2NH_2) by irradiation in isopropyl alcohol[1264] and with NaH.[1265]

OS **V**, 586; **VII**, 433.

19-51 Reduction of Miscellaneous Nitrogen Compounds

Isocyanate-methylamine transformation

$$R{-}N{=}C{=}O \xrightarrow{LiAlH_4} R{-}NH{-}CH_3$$

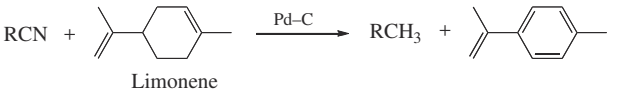
Isothiocyanate-methylamine transformation

$$R{-}N{=}C{=}S \xrightarrow{LiAlH_4} R{-}NH{-}CH_3$$

***N,N*-Dihydro-addition**

$$Ar{-}N{=}N{-}Ar \xrightarrow[cat]{H_2} Ar{-}NH{-}NH{-}Ar$$

Diazonium-arylhydrazone reduction



$$ArN_2^+Cl^- \xrightarrow{Na_2SO_3} ArNHNH_2$$

***N*-Hydro-de-nitroso-substitution**

$$R_2N{-}NO \xrightarrow[Ni]{H_2} R_2NH$$

Isocyanates and isothiocyanates are reduced to methylamines on treatment with $LiAlH_4$. Azo compounds are not usually reduced by $LiAlH_4$,[1266] (indeed these are the products from $LiAlH_4$ reduction of nitro compounds, Reaction **19-80**), but they can be reduced to hydrazo compounds by catalytic hydrogenation or with diimide[1267] (see Reaction **15-11**). Diazonium salts are reduced to hydrazines by sodium sulfite. This reaction probably has a nucleophilic mechanism.[1268] The initial product is a salt of hydrazinesulfonic acid, which is converted to the hydrazine by acid treatment. Diazonium salts can also be reduced to arenes (Reaction **19-69**). *N*-Nitrosoamines can be denitrosated to secondary amines by a number of reducing agents, including H_2 and a catalyst,[1269] $BF_3{-}THF{-}NaHCO_3$,[1270] and $NaBH_4{-}TiCl_4$,[1271] as well as by hydrolysis.[1272]

[1263] See Koziara, A.; Osowska-Pacewicka, K.; Zawadzki, S.; Zwierzak, A. ***1987***, 487. The Reactions **10-48**, **10-43**, and **19-50** have also been accomplished in one laboratory step: Koziara, A. *J. Chem. Res. (S)* ***1989***, 296.

Limonene

A cyano group can be reduced to a methyl group by treatment with a terpene (e.g., limonene), which acts as reducing agent in the presence of Pd–charcoal.[1273] Hydrogen gas (H_2) is also effective,[1274] although higher temperatures are required. The R group may be alkyl or aryl.

Aryl nitro compounds are reduced to diaryl hydrazines with Al−KOH in methanol.[1275]

OS **I**, 442; **III**, 475. Also see, OS **V**, 43.

D. Reactions in which a Heteroatom Is Removed from the Substrate

19-52 Reduction of Silanes to Methylene Compounds

_Si_-Hydrogen-uncoupling

$$R-SiR'_3 \longrightarrow R-H$$

In certain cases, the C−Si bond of silanes can be converted to C−H. α-Silyl esters are reduced to esters with mercuric acetate and tetrabutylammonium fluoride, for example.[1276]

19-53 Reduction of Alkyl Halides

Hydro-de-halogenation or Dehalogenation

$$RX \longrightarrow RH$$

This type of reduction can be accomplished with many reducing agents.[1277] A powerful but highly useful reagent ($LiAlH_4$)[1278] reduces almost all types of alkyl halide, including vinylic, bridgehead, and cyclopropyl halides.[1279] Reduction with lithium aluminum deuteride serves to introduce deuterium into organic compounds. An even more powerful reducing agent, lithium triethylborohydride ($LiEt_3BH$; Super hydride), rapidly reduces primary, secondary, allylic, benzylic, and neopentyl halides, but not tertiary (these give elimination) or aryl halides.[1280] A complex formed from lithium trimethoxyaluminum hydride [$LiAlH(OMe)_3$] and CuI is another powerful reagent, which reduces primary, secondary, tertiary, allylic, vinylic, aryl, and neopentyl halides.[1281] Sodium borohydride ($NaBH_4$) is a milder reducing agent that reduces primary, secondary, and some tertiary[1282]

halides in good yield, in a dipolar aprotic solvent (e.g., Me_2SO, DMF, or sulfolane)[1283] at room temperature or above without affecting other functional groups that would be reduced by $LiAlH_4$ (e.g., CO_2H, CO_2R, CN).[1284] A mixture of $NaBH_4$ and $InCl_3$ efficiently reduces secondary bromides.[1285] Borohydride exchange resin is also an effective reducing agent in the presence of metal catalysts [e.g., $Ni(OAc)_2$].[1286]

Other reducing agents[1287] include Zn (with acid or base), $SnCl_2$, and Et_3SiH in the presence of an $AlCl_3$,[1288] and also an Ir[1289] or In[1290] catalyst. Diethyl phosphonate–Et_3N,[1291] phosphorus tris(dimethylamide) $[(Me_2N)_3P]$,[1292] and organotin hydrides (R_nSnH_{4-n})[1293] (chiefly Bu_3SnH) usually used in conjunction with a radical-initiator (e.g., AIBN),[1294] or with transition metal salts (e.g., $InCl_3$).[1295] A water-soluble organotin hydride has been developed [$(MeOCH_2CH_2OCH_2CH_2CH_2)_3SnH$], which reduces alkyl halides.[1296] Raney nickel in 2-propanol reduces primary iodides in the presence of a lactone moiety.[1297] Aluminum amalgam efficiently reduced an iodohydrin to the alcohol.[1298]

Reduction, especially of bromides and iodides, can also be effected by catalytic hydrogenation.[1299] Raney nickel by itself can reduce alkyl halides.[1300] Homogeneous, chiral transition metal complexes can be used for the asymmetric hydrogenation of halides.[1301]

Alkali metals (e.g., Li[1302] or Na[1303] in *t*-BuOH or THF) are good reducing agents for the removal of all halogen atoms in a polyhalo compound (including vinylic, allylic, geminal, and even bridgehead halogens). Zinc and ammonium chloride in alcohol facilitates

dehalogenation with microwave irradiation.[1304] Nickel boride facilitates debromination.[1305] Propargylic halides can often be reduced with allylic rearrangement to give allenes.[1306]

The choice of a reducing agent usually depends on what other functional groups are present since each reducing agent reduces certain groups and not others. This type of selectivity is called *chemoselectivity*. A chemoselective reagent is one that reacts with one functional group (e.g., halide), but not another (e.g., C=O). For example, there are several reagents that reduce only the halogen of α-halo ketones, leaving the carbonyl group intact.[1307] Among them are decaborane with 10% Pd/C,[1308] Bi in aq THF[1309] or In metal in water,[1310] and *i*-$Bu_2AlH-SnCl_2$.[1311] Ionic liquids promote the selective debromination of α-bromo ketones.[1312] Debromination is also induced by indium metal in a carboxylic acid.[1313] In a similar chemoselective reaction, the halogen in α-haloimines has been reduced with $SnCl_2$/MeOH without reducing the C=N bond.[1314]

Tertiary alkyl, benzylic, and allylic halides are reduced by $NaBH_3CN-SnCl_2$[1315], but do not react with primary or secondary alkyl or aryl halides. Sodium cyanoborohydride ($NaBH_3CN$) in HMPA is another highly selective reagent, in this case for primary and secondary iodo and bromo groups.[1316] Most of the reducing agents mentioned reduce chlorides, bromides, and iodides, but organotin hydrides also reduce fluorides.[1317] See Section 19.B.ii-A for a discussion of selectivity in reduction reactions.

Alkyl halides, including fluorides and polyhalides, can be reduced with Mg and a secondary or tertiary alcohol (most often 2-propanol).[1318] This is actually an example of the occurrence in one step of the sequence:

$$RX \longrightarrow RMgX \xrightarrow{H^+} RH$$

More often the process is carried out in two separate steps (Reactions **12-36** and **12-22**).

Vinyl halides can be reduced to the corresponding alkene is some cases.[1319] When vinyl dibromides (e.g., $RCH{=}CBr_2$) are treated with $(MeO)_2P(=O)H$ and triethylamine, for example, the product is the vinyl bromide ($RCH{=}HBr$).[1320] Indium metal in ethanol accomplishes the same transformation.[1321] Similar reduction occurs when vinyl diiodides are treated with Zn−Cu in acetic acid.[1322]

With $LiAlH_4$ and most other metallic hydrides, the mechanism usually consists of simple nucleophilic substitution with attack by hydride ion equivalents. The mechanism is S_N2 rather than S_N1, since primary halides react better than secondary or tertiary (tertiary generally give alkenes or do not react at all) and since *Walden inversion* has been demonstrated. However, rearrangements found in the reduction of bicyclic tosylates with $LiAlH_4$ indicate that the S_N1 mechanism can take place.[1323] There is evidence that $LiAlH_4$ and other metal hydrides can also reduce halides by an SET mechanism,[1324] especially those (e.g., vinylic,[1325] cyclopropyl,[1326] or bridgehead halides) that are resistant to nucleophilic substitution. Reduction of halides by $NaBH_4$ in 80% aq diglyme[1327] and by BH_3 in nitromethane[1328] takes place by an S_N1 mechanism. It is known that $NaBH_4$ in sulfolane reduces tertiary halides possessing a β hydrogen by an elimination–addition mechanism.[1329]

The mechanism for reduction of alkyl halides is not always nucleophilic substitution. For example, reductions with organotin hydrides generally[1330] take place by free radical mechanisms,[1331] as do those with $Fe(CO)_5$.

19-54 Reduction of Alcohols[1332]

Hydro-de-hydroxylation or Dehydroxylation

$$ROH + H_2 \xrightarrow{\text{cat}} RH$$

The hydroxyl groups of most alcohols can seldom be cleaved by catalytic hydrogenation and alcohols are often used as solvents for hydrogenation of other compounds. However, benzyl-type alcohols undergo the reaction readily and have often been reduced.[1333] Diaryl

and triarylcarbinols are similarly easy to reduce with $LiAlH_4-AlCl_3$,[1334] with $NaBH_4$ in F_3CCOOH,[1335] and with iodine, water, and red phosphorus (OS **I**, 224). Other reagents have been used,[1336] including $Me_3SiCl-NaI$,[1337] $Et_3SiH-BF_3$,[1338] $SmI_2-THF-HMPA$,[1339] and Sn/HCl. The reduction of secondary alcohols was accomplished using Ph_2SiClH and $InCl_3$.[1340] 1,3-Diols are especially susceptible to hydrogenolysis. Tertiary alcohols can be reduced by catalytic hydrogenolysis when the catalyst is Raney nickel.[1341] Allylic alcohols (and ethers and acetates) can be reduced (often with accompanying allylic rearrangement) with Zn amalgam and HCl, as well as with certain other reagents.[1342] Reagents that reduce the OH group of α–hydroxy ketones without affecting the C=O group include red phosphorus–iodine,[1343] and Me_3SiI.[1344]

Alcohols can also be reduced indirectly by conversion to a sulfonate and reduction of that compound (Reaction **19-57**). The two reactions can be carried out without isolation of the sulfonate if the alcohol is treated with pyridine–SO_3 in THF, followed by $LiAlH_4$.[1345] Another indirect reduction that can be done in one step involves treatment of the alcohol (primary, secondary, or benzylic) with NaI, Zn, and Me_3SiCl.[1346] In this case, the alcohol is first converted to the iodide, which is reduced. For other indirect reductions of OH, see Reaction **19-59**.

The mechanisms of most alcohol reductions are obscure.[1347] Hydrogenolysis of benzyl alcohols can give inversion or retention of configuration, depending on the catalyst.[1348] The mechanism of electroreduction of allylic alcohols in acidic aqueous media has been examined.[1349]

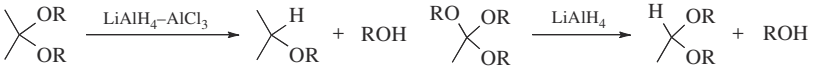
Oxygenated compounds (e.g., phenols, phenolic esters, and ethers) can be reduced.[1350] Phenols can be reduced by distillation over zinc dust or with HI and red phosphorus, but these methods are quite poor and are seldom feasible. Catalytic hydrogenation has also been used, but the corresponding cyclohexanol (see Reaction **15-13**) is a side product.[1351]

Much better results have been obtained by conversion of phenols to certain esters or ethers and reduction of the latter:

With a Pd−C catalyst, phenol derivatives are deoxygenated using Mg and MeO in the presence of ammonium acetate.[1355] Palladium-on-carbon also mediated hydrodexoygenation of phenol derivatives in the presence of diethylamine.[1356]

OS **VI**, 150. See also, OS **VII**, 476.

19-56 Replacement of Alkoxyl by Hydrogen



Hydro-de-alkoxylation or Dealkoxylation

$$R-O-R' \longrightarrow R-H + R'-H \qquad R, R' = \text{allyl, aryl, vinyl, benzylic}$$

Simple ethers are not normally cleaved by reducing agents, although such cleavage has sometimes been reported[1357] [e.g., THF treated with $LiAlH_4-AlCl_3$[1358] or with a mixture of $LiAlH(O\textit{t}\text{-Bu})_3$ and Et_3B[1359] gave 1-butanol; the latter reagent also cleaves methyl alkyl ethers].[1360] Certain types of ethers can be cleaved quite well by reducing agents.[1361]

Among these are allyl aryl,[1362] vinyl aryl,[1363] benzylic ethers,[1333,1364] and anisole[1365] (for epoxides, see Reaction **19-35**). 7-Oxobicyclo[2.2.1]heptanes can be reductively cleaved with Dibal-H and nickel catalysts.[1366] α-Methoxy ketones are demethoxylated (O=C−COMe → O=C−CH) with SmI_2.[1367]

Acetals and ketals are resistant to $LiAlH_4$ and similar hydrides, and carbonyl groups are often converted to acetals or ketals for protection (Reaction **16-5**). However, a combination of $LiAlH_4$ and $AlCl_3$[1368] does reduce acetals and ketals, removing one group, as shown above.[1369] The actual reducing agents in this case are primarily chloroaluminum hydride (AlH_2Cl) and dichloroaluminum hydride ($AlHCl_2$), which are formed from the reagents.[1370] This conversion can also be accomplished with Dibal-H,[1371] as well as with other reagents.[1372] Ortho esters are easily reduced to acetals by $LiAlH_4$ alone, offering a route to aldehydes, which are easily prepared by hydrolysis of the acetals (Reaction **10-6**). Mixed ketals [R(OMe)OR′] can be demethoxylated (to give RHOR′) with $Bn_3SnCl/NaCHBH_3$ in the presence of AIBN.[1373]

OS **III**, 693; **IV**, 798; **V**, 303. Also see, OS **III**, 742; **VII**, 386.

19-57 Reduction of Tosylates and Similar Compounds

Hydro-de-sulfonyloxy-substitution

$$RCH_2OTs + LiAlH_4 \longrightarrow RCH_3$$

Tosylates and other sulfonates can be reduced[1374] with $LiAlH_4$,[1375] with $NaBH_4$ in a dipolar aprotic solvent,[1376] with $LiEt_3BH$, with *i*-Bu_2AlH (Dibal-H),[1377] or with $Bu_3SnH-NaI$.[1378] The Ni catalyzed reduction of aryl tosylates proceeds in the presence

of borane hydrides.[1379] The scope of the reaction seems to be similar to that of **19-53**. When the reagent is $LiAlH_4$, alkyl tosylates are reduced more rapidly than iodides or bromides if the solvent is Et_2O, but the order is reversed in diglyme.[1380] The reactivity difference is great enough so that a tosylate function can be reduced in the presence of a halide and vice versa.

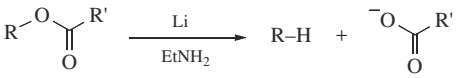
19-58 Hydrogenolysis of esters (Barton–McCombie Reaction)



Hydro-de-thioacetoxylation

Alcohols can readily be converted to carbonate and thiocarbonate derivatives. Under radical conditions,[1381] using AIBN (Sec. 14.A.i) and Bu_3SnH, the carbonate or thiocarbonate unit is reduced and replaced with hydrogen. The overall process is reduction of the ROH unit to RH and is called the *Barton–McCombie reaction*.[1382] Both $PhSiH_3$/AIBN[1383] and $PhSiH_2-BEt_3{\cdot}O_2$ can be used.[1384] This reaction can be catalytic in Bu_3SnH.[1385] Variations include reduction of ROCSNHPh derivatives using Ph_3SiH/BEt_3.[1386] Another variation used water as the hydrogen atom source when BMe_3 was used.[1387] Tetrabutylammonium peroxydisulfate and formate ion has been used.[1388]

19-59 Reductive Cleavage of Carboxylic Esters

Hydro-de-acyloxylation or Deacyloxylation

The alkyl group (R) of certain carboxylic esters can be reduced to RH[1389] by treatment with lithium in ethylamine.[1390] The reaction is successful when R is a tertiary or a sterically

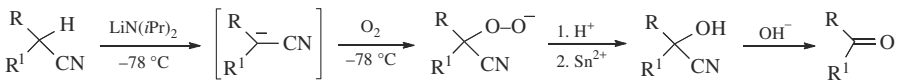
hindered secondary alkyl group. A free radical mechanism is likely.[1391] Similar reduction, also by a free radical mechanism, has been reported with sodium in HMPA–*t*-BuOH.[1392] In the latter case, tertiary R groups give high yields of RH, but primary and secondary R are converted to a mixture of RH and ROH. Both of these methods provide an indirect method of accomplishing Reaction **19-54** for tertiary R.[1393] The same thing can be done for primary and secondary R by treating alkyl chloroformates (ROCOCl) with tri-*n*-propylsilane in the presence of *tert*-butylperoxide[1394] and by treating thiono ethers [ROC(=S)W, where W can be OAr or other groups] with Ph_2SiH_2[1395] or Ph_3SiH[1396] and a free radical initiator. Allylic acetates can be reduced with $NaBH_4$ and a Pd complex,[1397] and with SmI_2–Pd(0).[1398] For other carboxylic ester reductions, see Reactions **19-62**, **19-38**, and **19-65**.



Note that acid chlorides can be reduced (R–COCl → R–H) using $(Me_3Si)_3SiH$/AIBN.[1399]

OS **VII**, 139.

19-60 Reduction of Hydroperoxides and Peroxides

$$R{-}O{-}O{-}H \xrightarrow{LiAlH_4} ROH$$

Hydroperoxides can be reduced to alcohols with $LiAlH_4$ or Ph_3P[1400] or by catalytic hydrogenation. This functional group is very susceptible to catalytic hydrogenation, as shown by the fact that a double bond may be present in the same molecule without being reduced.[1401]

The reaction is an important step in a method for the oxidative decyanation of nitriles containing an α hydrogen.[1402] The nitrile is first converted to the α-hydroperoxy nitrile by treatment with base at −78 °C followed by O_2. The hydroperoxy nitrile is then reduced to the cyanohydrin, which is cleaved (the reverse of Reaction **16-52**) to the corresponding ketone. The method is not successful for the preparation of aldehydes (R′ = H).

Peroxides are cleaved to 2 molar equivalents of alcohols by $LiAlH_4$, Mg/MeOH,[1403] or by catalytic hydrogenation. Peroxides can be reduced to ethers with $P(OEt)_3$.[1404] In a similar reaction, disulfides (RSSR′) can be converted to sulfides RSR′ by treatment with tris(diethylamino)phosphine $[(Et_2N)_3P]$.[1405]

OS **VI**, 130.

19-61 Reduction of Carbonyl to Methylene in Aldehydes and Ketones

Dihydro-de-oxo-bisubstitution

There are various ways of reducing the C=O group of aldehydes and ketones to CH_2.[1406] Two old but still popular methods are the *Clemmensen reduction*[1407] and the *Wolff–Kishner reduction*. The *Clemmensen reduction* consists of heating the aldehyde or ketone with zinc amalgam and aq HCl.[1408] Ketones are reduced more often than aldehydes. In the *Wolff–Kishner reduction*,[1409] the aldehyde or ketone is heated with hydrazine hydrate and a base (usually NaOH or KOH). The *Huang–Minlon modification*[1410] of the *Wolff–Kishner reduction*, in which the reaction is carried out in refluxing diethylene glycol, has completely replaced the original procedure. A microwave-assisted *Huang–Minlon* procedure has been reported.[1411] The reaction can be carried out under more moderate conditions (room temperature) in DMSO with potassium *tert*-butoxide as base.[1412] A new modification of the reduction treats a ketone with hydrazine in toluene with microwave irradiation, and subsequent reaction with KOH with microwave irradiation completes the *Wolff–Kishner reduction*.[1413] The *Wolff–Kishner reduction* can also be applied to the semicarbazones of aldehydes or ketones.

The *Clemmensen reduction* is usually easier to perform, but it fails for acid-sensitive and high-molecular-weight substrates. For these cases, the *Wolff–Kishner reduction* is quite useful. For high-molecular-weight substrates, a modified *Clemmensen reduction*, using activated zinc and gaseous HCl in an organic solvent (e.g., as ether or acetic anhydride) has proved successful.[1414] The *Clemmensen* and *Wolff–Kishner reductions* are complementary, since the former uses acidic and the latter basic conditions.

[1414] Toda, M.; Hayashi, M.; Hirata, Y.; Yamamura, S. *Bull. Chem. Soc. Jpn.* ***1972****, 45*, 264.

Both methods are fairly specific for aldehydes and ketones and can be carried out with many other functional groups present. However, certain types of aldehydes and ketones do not give normal reduction products. Under *Clemmensen* conditions,[1415] α-hydroxy ketones give either ketones (hydrogenolysis of the OH, Reaction **19-54**) or alkenes, and 1,3-diones usually undergo rearrangement (e.g., $MeCOCH_2COMe \rightarrow MeCOCHMe_2$).[1416] Neither method is suitable for α,β-unsaturated ketones, which give pyrazolines[1417] under *Wolff–Kishner* conditions. Under *Clemmensen* conditions, both groups of these molecules may be reduced or if only one group is reduced, it is the C=C bond.[1418] Sterically hindered ketones are resistant to both the *Clemmensen* and *Huang–Minlon* procedures, but can be reduced by vigorous treatment with anhydrous hydrazine.[1419] In the *Clemmensen reduction*, pinacols (Reaction **19-76**) are often side products.

Other reagents have also been used to reduce the C=O of aldehydes and ketones to CH_2.[1420] Among these are Me_3SiCl followed by $Et_3SiH/TiCl_4$,[1421] $Ni(OAc)_2$ on borohydride exchange resin,[1422] Et_3SiH on pyridinium poly(hydrogen fluoride) (PPHF),[1423] and, for aryl ketones (ArCOR and ArCOAr), $NaBH_3CN$ in THF–aq HCl,[1424] Ni−Al in H_2O,[1425] $HCOONH_4$−Pd−C,[1426] or trialkylsilanes in F_3CCOOH.[1427] Hydrogenation with a heterogeneous Cu–silica catalyst has been used.[1428] Silanes (e.g., Et_3SiH) and a triarylborane catalyst reduce aliphatic aldehydes to methyl, $-CHO \rightarrow -CH_3$.[1429] Zinc oxide/triethylsilane has been used,[1430] and also titanocene dichloride $[(C_5H_5)_2TiCl_2]$.[1431] Most of these reagents also reduce aryl aldehydes (ArCHO) to methylbenzenes ($ArCH_3$).[1432] One carbonyl group of 1,2-diketones can be selectively reduced by H_2S with an amine catalyst[1433] or by HI in refluxing acetic acid.[1434] One carbonyl group of quinones (e.g., **41**), can be reduced with Cu and H_2SO_4 or with Sn and HCl.[1435] One carbonyl group of 1,3-diketones was selectively reduced by catalytic hydrogenolysis.[1436]

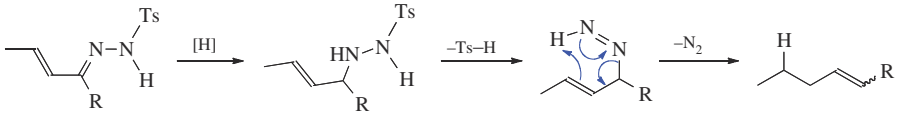
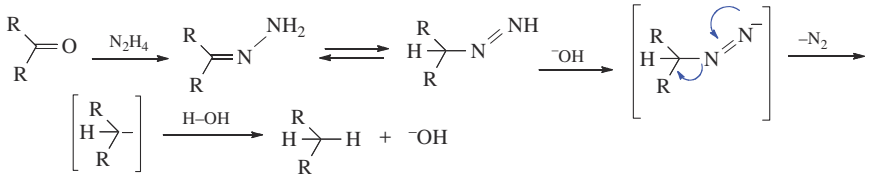
Simply heating a ketone in supercritical 2-propanol reduces the ketone to the methylene compound.[1437]



41

An indirect method of accomplishing the reaction is reduction of tosylhydrazones ($R_2C{=}N{-}NHTs$) to R_2CH_2 with $NaBH_4$, BH_3, catecholborane, bis(benzyloxy)borane, or $NaBH_3CN$. The reduction of α,β-unsaturated tosylhydrazones with $NaBH_3CN$, with $NaBH_4{-}HOAc$, or with catecholborane proceeds with migration of the double bond to the position formerly occupied by the carbonyl carbon, even if this removes the double bond from conjugation with an aromatic ring,[1438] for example,



A cyclic mechanism is apparently involved:

Another indirect method is conversion of the aldehyde or ketone to a dithioacetal or ketal, and desulfurization using Raney nickel or another reagent (Reaction **14-27**).

The first step in the mechanism[1439] of the *Wolff–Kishner reduction* consists of formation of the hydrazone (**16-14**). It is this species that undergoes reduction in the presence of base, most likely in the following manner:

[1437] Hatano, B.; Tagaya, H. *Tetraehedron Lett.* ***2003****, 44*, 6331.
[1438] Hutchins, R.O.; Natale, N.R. *J. Org. Chem.* ***1978****, 43*, 2299; Greene, A.E. *Tetrahedron Lett.* ***1979***, 63.

Not much is known about the mechanism of the *Clemmensen reduction*. Several mechanisms have been proposed,[1440] including one going through a zinc–carbene intermediate.[1441] One thing reasonably certain is that the corresponding alcohol is not an intermediate, since alcohols prepared in other ways fail to give the reaction. Note that the alcohol is not an intermediate in the *Wolff–Kishner reduction* either.

It is interesting to see that amines can be deaminated to give the corresponding methylene compounds with low-valent titanium ($TiCl_3$/Li/THF).[1442]

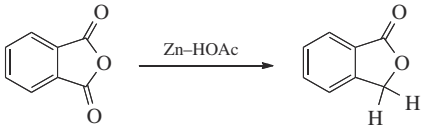
19-62 Reduction of Carboxylic Esters to Ethers

Dihydro-de-oxo-bisubstitution

$$RCOOR' \xrightarrow[LiAlH_4]{BF_3-\text{etherate}} RCH_2OR'$$

Carboxylic esters and lactones have been reduced to ethers, although 2 molar equivalents of alcohol are more commonly obtained (Reaction **19-38**). Reduction to ethers has been accomplished with a reagent prepared from BF_3–etherate and either $LiAlH_4$, $LiBH_4$, or $NaBH_4$,[1443] with trichlorosilane and UV light,[1444] and with catalytic hydrogenation. The reaction with the BF_3 reagent apparently succeeds with secondary R′, but not with primary R′, which give **19-38**. Acyloxy groups are reduced by cleavage of the C−C=O bond, R(Ar)COO−C → C−H) with an excess of Ph_2SiH_2 and di-*tert*-butyl peroxide.[1445] Esters are reduced to ethers using Et_3SiH and $TiCl_4$,[1446] BF_3,[1447] In(III) compounds,[1448] or $FeCl_3$.[1449] Lactones are converted to cyclic ethers[1450] by treatment with Cp_2TiCl_2 followed by Et_3SiH on Amberlyst 15.[1451]



Thiono esters (RCSOR′) can be reduced to ethers (RCH_2OR') with Raney nickel (Reaction **14-27**).[1452] Reaction of thio esters (e.g., C−OC(=O)Ph) with Ph_2SiH_2 and Ph_3SnH with BEt_3, followed by AIBN (Sec. 14.A.i) leads to reduction of the C=S unit to give an ether.[1453] Since the thiono esters can be prepared from carboxylic esters (Reaction **16-11**), this provides an indirect method for the conversion of carboxylic esters to ethers. Thiol esters (RCOSR′) have been reduced to thioethers (RCH_2SR').[1454]

19-63 Reduction of Cyclic Anhydrides to Lactones and Acid Derivatives to Alcohols

Dihydro-de-oxo-bisubstitution

Cyclic anhydrides are reduced with Zn−HOAc to give lactones, and also with hydrogen and Pt or $RuCl_2(Ph_3P)_3$,[1455] with $NaBH_4$.[1456] With cyclic anhydrides the reaction with $LiAlH_4$ can be controlled to give either diols or lactones,[1457] although diols are the more usual product. A BINOL–$LiAlH_4$–EtOH complex, however, gives smooth reduction to the lactone.[1458] With some reagents the reaction can be accomplished regioselectively; that is, only a specific one of the two C=O groups of an unsymmetrical anhydride is reduced.[1459] Open-chain anhydrides either are not reduced at all (e.g., with $LiAlH_4$ or $NaBH_4$) or give 2 molar equivalents of alcohol. The $NaBH_4$ in THF, with dropwise addition of methanol, reduces open-chain anhydrides to 1 equiv of primary alcohol and 1 equiv of carboxylic acid.[1460]

Acyl halides are reduced[1461] to alcohols by $LiAlH_4$ or $NaBH_4$, as well as by other metal hydrides (Table 19.4), but not by borane.

In general, reduction of amides to alcohols is difficult. More commonly the amide is reduced to an amine. An exception uses LiH_2NBH_3 to give the alcohol.[1462] Reduction with sodium metal in propanol also gives the alcohol.[1463] Acyl imidazoles are also reduced to the corresponding alcohol with $NaBH_4$ in aq HCl.[1464]

There are no *Organic Syntheses* references, but see OS **II**, 526, for a related reaction. See OS **VI**, 482 for reduction to alcohols and OS **IV**, 271 for reduction of acyl halides.

19-64 Reduction of Amides to Amines

Dihydro-deoxo-bisubstitution

$$RCONH_2 \xrightarrow{LiAlH_4} RCH_2NH_2$$

A useful reagent is $LiAlH_4$, although the reaction is more difficult than the reduction of most other functional groups. Other groups are often reduced without disturbing an amide function. Although $NaBH_4$ by itself does not reduce amides, it does so in the presence

of certain other reagents[1465] including iodine.[1466] Lithium borohydride reduces acetamides.[1467] Substituted amides can be reduced with these powerful reagents, and secondary amides are reduced to secondary amine and tertiary amides to tertiary amines. Borane[1468] and sodium in 1-propanol[1469] are good reducing agents for all three types of amides. Lithium triethylborohydride produces the alcohol with most *N,N*-disubstituted amides, but not with unsubstituted or *N*-substituted amides.[1470] Sodium (dimethylamino)borohydride reduces unsubstituted and disubstituted, but not monosubstituted amides.[1471]

Amides can be reduced[1472] to amines by catalytic hydrogenation,[1473] but high temperatures and pressures are usually required. Another reagent that reduces disubstituted amides to amines is trichlorosilane.[1474] Other silanes (e.g., Et_3SiH) in the presence of a Re[1475] Pt,[1476] In,[1477] Zn,[1478] or Ru,[1479] catalyst, reduce amides to amines. Electrolytic reduction of carbamates to give an amine are possible.[1480]

Hantzsch esters (see Reactions **15-14** and **16-17**) have been used for metal-free reduction of amides to amines.[1481]

With some $RCONR_2$, $LiAlH_4$ causes cleavage, and the aldehyde (Reaction **10-41**) or alcohol is obtained. Lactams are reduced to cyclic amines in high yields with $LiAlH_4$, although cleavage sometimes occurs here too. A mixture of $LiBHEt_3/Et_3SiH$ is also effective.[1482] Lactams are also reduced to cyclic amines with 9-BBN[1483] (Reaction **15-16**) or $LiBH_3NMe_2$.[1484]

Imides are generally reduced on both sides,[1485] although it is sometimes possible to stop with just one. Both cyclic and acyclic imides have been reduced in this manner, although with acyclic imides cleavage is often obtained.[1486]

Note that imides can be reduced to hydroxy lactams using different reagents, including $NaBH_4$.[1487]

OS **IV**, 339, 354, 564; **VI**, 382; **VII**, 41.

19-65 Reduction of Carboxylic Acids and Esters to Alkanes

Trihydro-de-alkoxy,oxo-tersubstitution, and so on

$$RCOOR' \xrightarrow{(C_5H_5)_2TiCl_2} RCH_3 + R'OH$$

The reagent titanocene dichloride reduces carboxylic esters in a different manner from that of Reactions **19-59**, **19-62**, or **19-38**. The products are the alkane RCH_3 and the alcohol $R'OH$. The mechanism probably involves an alkene intermediate. Aromatic acids can be reduced to methylbenzenes by a procedure involving refluxing first with trichlorosilane in MeCN, then with tripropylamine added, and finally with KOH and MeOH (after removal of the MeCN).[1488] The following sequence has been suggested[1488]:

$$ArCOOH \xrightarrow{SiHCl_3} (ArCO)_2O \xrightarrow[R_3N]{SiHCl_3} ArCH_2SiCl_3 \xrightarrow[MeOH]{KOH} ArCH_3$$

Esters of aromatic acids are not reduced by this procedure, so an aromatic COOH group can be reduced in the presence of a $COOR'$ group.[1489] However, it is also possible to reduce aromatic ester groups, by a variation of the trichlorosilane procedure.[1490] Both *o*- and *p*-hydroxybenzoic acids and their esters have been reduced to cresols ($HOC_6H_4CH_3$) with sodium bis(2-methoxyethoxy)aluminum hydride [$NaAlH_2(OC_2H_4OMe)_2$, Red-Al].[1491] Heating a 2-pyridylbenzyl ester with ammonium formate and a Ru catalyst leads to reduction of the CH_3COO unit to the alkane.[1492]

Carboxylic acids can also be converted to alkanes, indirectly,[1493] by reduction of the corresponding tosylhydrazides ($RCONHNH_2$) with $LiAlH_4$ or borane.[1494]

OS **VI**, 747.

19-66 Hydrogenolysis of Nitriles

Hydro-de-cyanation

$$R{-}CN \longrightarrow R{-}H$$

This transformation is not common, but given the proliferation of nitriles in organic chemistry, it is potentially quite useful. In the presence of mercuric compounds, tertiary nitriles can be reduced to the hydrocarbon with sodium cyanoborohydride.[1495]

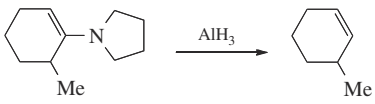
gem-Dinitriles can be reduced to the corresponding mono-nitrile with SmI_2.[1496] Hydrosilanes facilitate reductive cleavage of nitriles in the presence of a Rh catalyst.[1497]



19-67 Reduction of the C−N Bond

Hydro-de-amination or Deamination

$$RNH_2 \longrightarrow RH$$

Benzylic amines are particularly susceptible to hydrogenolysis by catalytic hydrogenation[1498] or dissolving metal reduction.[1499] Note that the *Wolff–Kishner reduction* in Reaction **19-61** involved formation of a hydrazone and deprotonation by base that led to loss of nitrogen and reduction. Ceric ammonium nitrate in aq acetonitrile has also been shown to reductively cleave the *N*-benzyl group.[1500] Primary amines have been reduced to RH with hydroxylamine-*O*-sulfonic acid and aq NaOH to give the hydrocarbon, nitrogen gas, and the sulfate anion.[1501] It is postulated that R−N=N−H is an intermediate that decomposes to the carbocation. An indirect means of achieving the same result is the conversion of the primary amine to the sulfonamide ($RNHSO_2R'$) (Reaction **16-102**) and subsequent treatment with NH_2OSO_2OH[1502] or NaOH, and then NH_2Cl.[1503] Tosylaziridines derived from terminal alkenes are reduced to the corresponding primary tosylamine with polymethylhydrosiloxane/Pd-C.[1504] Aziridines can be reduced in the same way as epoxides (Reaction **19-35**).

Other indirect methods involve reduction of *N,N*-ditosylates (Sec. 10.G.iii) with $NaBH_4$ in HMPA[1505] and modifications of the *Katritzky pyrylium–pyridinium method*.[1506] Allylic and benzylic amines[1333] can be reduced by catalytic hydrogenolysis. Aziridines can be reductively opened with SmI_2[1507] or with Bu_3SnH and AIBN.[1508] The C−N bond of enamines is reductively cleaved to give an alkene with alane (AlH_3)[1509]:

and with 9-BBN (Reaction **15-16**) or borane methyl sulfide (BMS).[1510] Since enamines can be prepared from ketones (Reaction **16-13**), this is a way of converting ketones to alkenes.

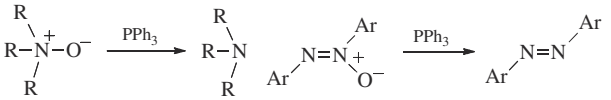
In the latter case, BMS gives retention of configuration [an (*E*)-isomer gives the (*E*)-product], while 9-BBN gives the other isomer.[1510] Diazo ketones are reduced to methyl ketones by HI: $RCOCHN_2 + HI \rightarrow RCOCH_3$.[1511]



Quaternary ammonium salts can be cleaved with $LiAlH_4$, $R_4N^+ + LiAlH_4 \rightarrow R_3N + R^-$, as can quaternary phosphonium salts (R_4P^+). Other reducing agents have also been used (e.g., lithium triethylborohydride, which preferentially cleaves methyl groups,[1512] and Na in liquid ammonia). When quaternary salts are reduced with Na(Hg) in water, the reaction is known as the *Emde reduction*. However, this reagent is not applicable to the cleavage of ammonium salts with four *saturated* alkyl groups.

Nitro compounds (RNO_2) can be reduced to RH[1513] by sodium methylmercaptide (CH_3SNa) in an aprotic solvent[1514] or by Bu_3SnH.[1515] Both reactions have free radical mechanisms.[1516] Tertiary nitro compounds can be reduced to RH by NaHTe.[1517] The nitro group of aromatic nitro compounds has been removed with sodium borohydride.[1518] Reduction of the C−N bond on aromatic amines with Li metal in THF generates the aryl compounds.[1519] Sodium nitrite, sodium bisulfite in EtOH/water/acetic acid does a similar reduction.[1520] Conversion of the aniline derivative to the methanesulfonamide and subsequent treatment with NaH and NH_2Cl gives the same result.[1521] The Bu_3SnH reagent also reduces isocyanides (RNC, prepared from RNH_2 by formylation followed by Reaction **17-31**) to RH,[1522] a reaction that can also be accomplished with Li or Na in liquid NH_3,[1523] or with K and a crown ether in toluene.[1524] α-Nitro ketones can be reduced to ketones with $Na_2S_2O_4$−Et_3SiH in HMPA−H_2O.[1525]

Amine oxides[1526] and azoxy compounds (both alkyl and aryl)[1527] can be reduced practically quantitatively with triphenylphosphine.[1528] Other reducing agents have also been used, including $LiAlH_4$, $NaBH_4/LiCl$,[1529] H_2-Ni, PCl_3, Ga/H_2O,[1530] or $In/TiCl_4$.[1531] Indium metal with aq ammonium chloride in methanol gives good yields of pyridine from pyridine *N*-oxide.[1532] Similar results are obtained using ammonium formate and Raney nickel[1533] or zinc.[1534] Sodium in ethanol, in a sealed tube, reduces pyridine *N*-oxide to pyridine.[1535] Similar reduction was accomplished with $Mo(CO)_6$ in ethanol.[1536] Indium (III) chloride has been used for the reduction of quinoline *N*-oxide to quinoline.[1537] Nitrile oxides[1538] ($R-C\equiv N^+-O^-$) can be reduced to nitriles with trialkylphosphines,[1539] and isocyanates (RNCO) to isocyanides (RNC) with $Cl_3SiH-Et_3N$.[1540]

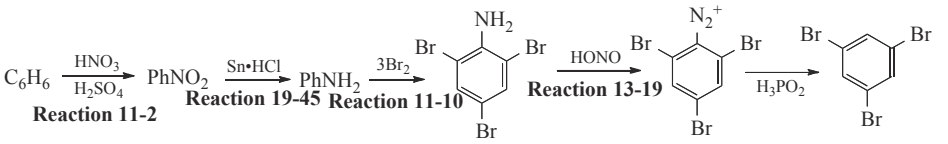
Analogous to amino *N*-oxides, phosphine oxides ($R_3P=O$) are reduced to phosphines (R_3P). Treatment of a phosphine oxide with MeOTf followed by reduced with $LiAlH_4$[1541] or Dibal-H[1542] gives the phosphine. Chiral phosphine oxides are reduced to the phosphine with excellent enantioselectivity using PPh_3 and Cl_3SiH.[1543]

OS **IV**, 166. See also, OS **VIII**, 57.

19-69 Replacement of the Diazonium Group by Hydrogen

Dediazoniation or **Hydro-de-diazoniation**

$$ArN_2^+ + H_3PO_2 \longrightarrow ArH$$



Reduction of a diazonium group (*dediazoniation*) provides an indirect method for the removal of an amino group from an aromatic ring.[1544] A common method uses hypophosphorous acid (H_3PO_2), although many other reducing agents[1545] have been used,

including HMPA,[1546] thiophenol,[1547] and sodium stannite (Na_2SnO_2). Ethanol was the earliest reagent used, and it frequently gives good yields, but ethers (ArOEt) are often side products. When H_3PO_2 is used, 5–15 molar equivalents of this reagent are required per molar equivalent of substrate. Diazonium salts can be reduced in nonaqueous media by several methods, including treatment with Bu_3SnH or Et_3SiH in ethers or MeCN[1548] and by isolation as the BF_4^- salt and reduction of this with $NaBH_4$ in DMF.[1549] Aromatic amines can be deaminated ($ArNH_2 \rightarrow ArH$) in one laboratory step by treatment with an alkyl nitrite in DMF[1550] or boiling THF.[1551] The corresponding diazonium salt is an intermediate.

Not many investigations of the mechanism have been carried out. It is generally assumed that the reaction of diazonium salts with ethanol to produce ethers takes place by an ionic (S_N1) mechanism while the reduction to ArH proceeds by a free radical process.[1552] The reduction with H_3PO_2 is also believed to have a free radical mechanism.[1553] In the reduction with $NaBH_4$, an aryldiazene intermediate (ArN=NH) has been demonstrated,[1554] arising from nucleophilic attack by BH_4^- on the β nitrogen. Such diazenes can be obtained as moderately stable (half-life of several hours) species in solution.[1555] It is not entirely clear how the aryldiazene decomposes, but there are indications that either the aryl radical (AR•) or the corresponding anion (Ar^-) may be involved.[1556]

The dediazoniation reaction is used for functionalization of aromatic rings, to remove an amino group after it has been used to direct one or more other groups to ortho and para positions. For example, the compound 1,3,5-tribromobenzene cannot be prepared by direct bromination of benzene because the bromo group is ortho–para directing; however, this compound is easily prepared by the following sequence:

Many other compounds that would otherwise be difficult to prepare are easily synthesized with the aid of the dediazoniation reaction.

Unwanted dediazoniation can be suppressed by using hexasulfonated calix[6]arenes (see Sec. 3.C.ii).[1557]

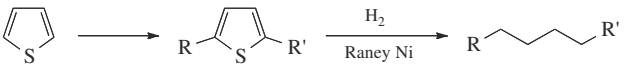
19-70 Desulfurization



Hydro-de-thio-substitution, and so on

$$RSH \longrightarrow RH \quad RSR' \longrightarrow RH + R'H \quad RS(O)_nR' \longrightarrow RH + R'H$$

Thiols and thioethers,[1558] both alkyl and aryl, can be desulfurized by hydrogenolysis with Raney nickel.[1559] The hydrogen is usually not applied externally, since Raney nickel typically contains enough hydrogen for the reaction. Other sulfur compounds can be similarly desulfurized, including disulfides, thiono esters,[1560] thioamides, sulfoxides, and thioacetals.[1561] Reduction of thioacetals is an indirect way of accomplishing reduction of a carbonyl to a methylene group (see Reaction **19-61**), and it can also give the alkene if a hydrogen atom is present.[1562] In most of the examples given, R can also be aryl. Other reagents[1563] have also been used.[1564] Reductive cleavage of sulfones and sulfonamides occurs with organobases [e.g., bis(imidazolylidenes)].[1565]

Lithium aluminum hydride reduces most sulfur compounds with cleavage of the C–S bond, including thiols.[1566] Thioesters can be reduced with Ni_2B (from $NiBr_2/NaBH_4$).[1567] β-Ketosulfones are reduced with $TiCl_4$–Zn[1568] or $TiCl_4$–Sm.[1569]

An important special case of RSR reduction is desulfurization of thiophene derivatives. This proceeds with concomitant reduction of the double bonds. Many compounds have been made by alkylation of thiophene to **42**, followed by reduction to give the alkane.

42

Thiophenes can also be desulfurized to alkenes ($RCH_2CH{=}CHCH_2R'$ from **42**) with a nickel boride catalyst prepared from $NiCl_2$ and $NaBH_4$ in CH_3OH.[1570] Only one SR group of a dithioacetal is reduced by treatment with borane–pyridine in trifluoroacetic acid or in CH_2Cl_2 in the presence of $AlCl_3$.[1571] Phenyl selenides (RSePh) can be reduced to RH with

Ph_3SnH[1572] and with nickel boride.[1573] Cleavage of the C−Se bond can also be achieved with SmI_2.[1574]

The exact mechanism of the Raney nickel reactions is still in doubt, although they are probably of the free radical type.[1575] It has been shown that reduction of thiophene proceeds through butadiene and butene, not through 1-butanethiol or other sulfur compounds; that is the sulfur is removed before the double bonds are reduced. This was demonstrated by isolation of the alkenes and the failure to isolate any potential sulfur-containing intermediates.[1576]

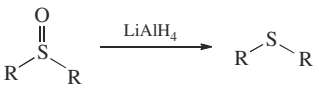
19-71 Reduction of Sulfonyl Halides and Sulfonic Acids to Thiols or Disulfides

$$RSO_2Cl \xrightarrow{LiAlH_4} RSH$$



Thiols can be prepared by the reduction of sulfonyl halides[1577] with $LiAlH_4$. Usually, the reaction is carried out on aromatic sulfonyl chlorides. Zinc and acetic acid, and HI, also give the reduction. Sulfonic acids have been reduced to thiols with a mixture of triphenylphosphine and either I_2 or a diaryl disulfide.[1578] For the reduction of sulfonyl chlorides to sulfinic acids, see Reaction **16-104**.

Disulfides (RSSR) can also be produced.[1579] Other sulfonic acid derivatives can be converted to disulfides. Esters (e.g., PhSAc) are converted to disulfides (PhS-SPh) with Clayan and microwave irradiation.[1580] Thiobenzoate derivatives (PhSBz) are similarly converted to PhS−SPh with SmI_2.[1581] In a similar manner, RS−SO_3Na is converted to RS−SR when heated with Sm metal in water.[1582]

Sulfoxides can be reduced to sulfides by many reagents,[1583] including $LiAlH_4$, HI, Bu_3SnH,[1584] H_2-Pd-C,[1585] $NaBH_4-NiCl_2$,[1586] $NaBH_4/I_2$,[1587] catecholborane,[1588] BH_3 with a Mo catalyst,[1589] a Mo/In system,[1590] Ti compounds,[1591] and Sm/methanolic NH_4Cl with ultrasound.[1592] Sulfoxides are deoxygenated by treatment with 2,4-diphenyl-1,3-diselenadiphosphetane-2,4-diselenide.[1593] Sulfones, however, are usually more difficult to reduce, but they have been reduced to sulfides with Dibal-H.[1594] A less general reagent is $LiAlH_4$, which reduces some sulfones to sulfides, but not others.[1595] Both sulfoxides and sulfones can be reduced by heating with sulfur, which is oxidized to SO_2, although the reaction with sulfoxides proceeds at a lower temperature. It has been shown by using substrate labeled with ^{35}S that sulfoxides simply give up the oxygen to the sulfur, but that the reaction with sulfones is more complex, since ~75% of the original radioactivity of the sulfone is lost.[1596] This indicates that most of the sulfur in the sulfide product comes in this case from the *reagent*. There is no direct general method for the reduction of sulfones to sulfoxides, but an indirect method has been reported.[1597] Selenoxides can be reduced to selenides with a number of reagents.[1598]

Li converts *N*-benzylamines to the amine.[1601] In the case of *N,N*-dimethyl amines, $RuCl_3$ and H_2O_2 demethylate the amine ($ArNMe_2 \rightarrow ArNHMe$).[1602] Tribenzylamines are dealkylated to give the dibenzylamine with ceric ammonium nitrate in aq acetonitrile.[1603] *N*-Benzyl indoles are cleaved to indoles with O_2, DMSO/K*O-t*-Bu[1604] or with tetrabutylammonium fluoride.[1605] *N*-Demethylation of alkaloids was reported using a Fe mediated two-step procedure.[1606] *N*-Deallylation and debenzylation of amines occurs with alkali metals on silica.[1607]

The process is not limited to amines. Amides can also be dealkylated. *N*-Benzyl amides are debenzylated in the presence of NBS and AIBN.[1608] Scandium triflate removes *N-tert*-butyl from amides.[1609]

N-Alkyl sulfonamides are dealkylated with $PhI(OAc)_2$ and I_2 with ultrasound to give a primary sulfonamide.[1610] Similar results are obtained with H_5IO_6 and a Cr catalyst.[1611] *tert*-Butyl sulfonamides are cleaved to the primary sulfonamide with BCl_3.[1612]

19-74 Reduction of Azo, Azoxy, and Hydrazo Compounds to Amines

Azo, azoxy, and hydrazo compounds can all be reduced to amines.[1613] Metals (notably Zn) and acids, and $Na_2S_2O_4$, are frequently used as reducing agents, and Bu_3SnH with a Cu catalyst has been used.[1614] Borane reduces azo compounds to amines, although it does not reduce nitro compounds.[1615] Lithium aluminum hydride does not reduce hydrazo compounds or azo compounds, although with the latter, hydrazo compounds are sometimes isolated. With azoxy compounds, $LiAlH_4$ gives only azo compounds (Reaction **19-68**). Note that azo compounds are reduced to the hydrazine by reaction with hydrazine hydrate in ethanol,[1616] or with Fe powder in ammonium chloride.[1617]

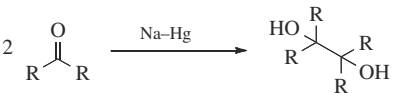
19-75 Reduction of Disulfides to Thiols

S-Hydrogen-uncoupling

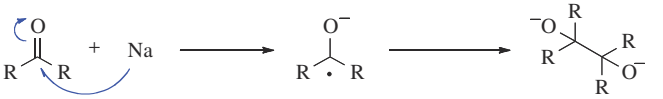
$$\mathrm{RSSR} \xrightarrow[\mathrm{H^+}]{\mathrm{Zn}} 2\,\mathrm{RSH}$$

Disulfides can be reduced to thiols by mild reducing agents[1618] (e.g., Zn and dilute acid, In and NH_4Cl/EtOH,[1619] or Ph_3P and H_2O).[1620] The reaction can also be accomplished simply by heating with alkali.[1621] Among other reagents used have been $LiAlH_4$, $NaBH_4/ZrCl_4$,[1622] Mg/MeOH,[1623] and hydrazine or substituted hydrazines.[1624]



Aryl diselenides are similarly cleaved to selenols (ArSeH) with Cp_2TiH followed by $Ph_2I^+X^-$.[1625]

OS **II**, 580. Also see, OS **IV**, 295.



F. Reductive Coupling

19-76 Bimolecular Reduction of Aldehydes and Ketones to 1,2-Diols and Imines to 1,2-Diamines

2/*O*-Hydrogen-coupling and 2/*N*-Hydrogen-coupling

1,2-Diols (pinacols) can be synthesized by reduction of aldehydes and ketones with active metals (e.g., Na, Mg, or Al).[1626] Aromatic ketones give better yields than aliphatic ones. The use of a $Mg-MgI_2$ mixture has been called the *Gomberg–Bachmann pinacol synthesis*.[1627] As with a number of other reactions involving Na, there is a direct electron transfer that converts the ketone or aldehyde to a ketyl, which dimerizes.

Other reagents have been used,[1628] including Sm,[1629] SmI_2,[1630] Pr,[1631] Yb,[1632] In with ultrasound,[1633] $InCl_3$ catalyst with Mg,[1634] $InCl_3$/Al in H_2O,[1635] Al/$TiCl_3$,[1636] VCl_3/Zn in H_2O,[1637] activated Mn,[1638] Zn,[1639] and a low-valent Ti reagent[1640] (see Reaction **19-76**). Unsymmetrical coupling between two different ketones has been accomplished using $TiCl_3$ in aqueous solution,[1641] and coupling of two different aldehydes has been achieved by the use of a V complex.[1642] Two aldehydes have also been coupled using Mg in water.[1643] Coupling leads to a mixture of *syn*- and *anti*-diols. "Syn-selective" reagents are Cp_2TiCl_2/Mn,[1644] $TiCl_4$/Bu_4I,[1645] TiI_4,[1646] and $NbCl_3$.[1647] "Anti-selective" coupling reactions are also known: Ti–salen,[1648] Mg with a $NiCl_2$ catalyst,[1649] and Sm/$SmCl_3$.[1650] Aryl aldehydes are coupled to give the bis(trimethylsilyl) ether using Mn, Me_3SiCl and Cp_2TiCl_2.[1651]

Stereoselective pinacol coupling reactions are well known.[1652] Chiral additives with pinacol couplings lead to formation of a diol with moderate to good enantioselectivity.[1653] A crossed-pinacol coupling was reported using Et_2Zn and with a BINOL catalyst gave good enantioselectivity.[1654] Enantioselective coupling was reported using a chiral salen–Mo

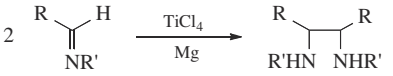
complex.[1655] A combination of Mg and Me_3SiCl was also used to effect a crossed-pinacol.[1656] Chiral metal complexes in conjunction with a metal leads to diol formation with good enantioselectivity.[1657]

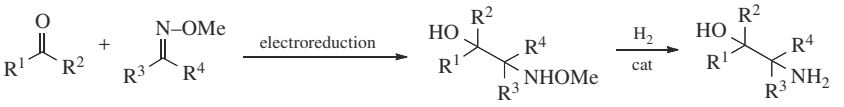
Intramolecular pinacol coupling reactions are known, giving cyclic 1,2-diols.[1658] Dialdehydes have been cyclized by reaction with $TiCl_3$ to give cyclic 1,2-diols in good yield.[1659]

A variation of the pinacol coupling treats acyl nitriles with In metal and ultrasound to give a 1,2-diketone.[1660] Another variation couples acetals to give 1,2-diols.[1661]

The photochemical dimerization of ketones to 1,2-diols is one of the most common photochemical reactions.[1662] The substrate, which is usually a diaryl or aryl alkyl ketone, is irradiated with UV light in the presence of a hydrogen donor (e.g., isopropyl alcohol, toluene, or an amine).[1663] In the case of benzophenone, irradiated in the presence of 2-propanol, the ketone molecule initially undergoes $n \rightarrow \pi*$ excitation, and the singlet species thus formed crosses to the T_1 state with a very high efficiency.



42



The T_1 species abstracts hydrogen from the alcohol (Sec. 7.A.vii, category 4) and then dimerizes. The *i*PrO$^{\bullet}$ radical, which is formed by this process, reacts by atom transfer of H$^{\bullet}$ to another molecule of ground-state benzophenone, producing acetone and another molecule of **51**. This mechanism[1664] predicts that the quantum yield for the disappearance of benzophenone should be 2, since each quantum of light results in the conversion of 2 equiv of benzophenone to **42**. Under favorable experimental conditions, the observed quantum yield does approach 2. Benzophenone abstracts hydrogen with very high efficiency. Other aromatic ketones are dimerized with lower quantum yields, and some (e.g., *p*-aminobenzophenone, *o*-methylacetophenone) cannot be dimerized at all in 2-propanol (although *p*-aminobenzophenone, e.g., can be dimerized in cyclohexane[1665]). The reaction has also been carried out electrochemically.[1666]

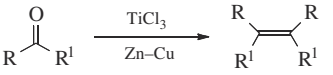
A coupling reaction similar to pinacol coupling has been used with imines, which dimerize to give 1,2-diamines. A number of reagents have been used, including treatment with $TiCl_4$–Mg,[1667] In/aq EtOH,[1668] Zn/aq NaOH,[1669] or SmI_2.[1670]

When electroreduction was used, it was possible to obtain cross-products by coupling a ketone to an *O*-methyl oxime[1671]: *O*-Methyl oxime ethers are coupled to give 1,2-diamines using Zn and $TiCl_4$.[1672] Aldehydes are converted to 1,2-diamines by treatment with TMS_2NH, NaH, and Li metal in 5 M $LiClO_4$ in ether, with sonication.[1673] Aldehydes are coupled with *N*-sulfinyl imines to give *N*-sulfinyl amino alcohols in the presence of SmI_2.[1674] Hemiaminals are coupled to give 1,2-diamines with TiI_4/Zn.[1675] Amides are converted to 1,2-diamines with Cp_2TiF_2 and $PhMeSiH_2$.[1676] Samarium(II) iodide was used to couple iminium salts, giving the 1,2-diamine.[1677] Ketones can be treated with Yb, and then an imine to give amino alcohols.[1678]



The *N*-methoxyamino alcohol could then be reduced to the amino alcohol.[1671] A photochemical coupling has also been reported.[1679] A variation of this reaction treats an imine with Yb in THF/HMPA, and then an aldehyde to give a 1,2-bis(imine).[1680]

generated with $TiCl_3$ and a Zn–Cu couple.[1682] This is called the *McMurry reaction*.[1683] The reagent produced in this way is called a *low-valent titanium reagent*, and the reaction has also been accomplished[1684] with low-valent Ti reagents prepared in other ways, for example, from Mg and a $TiCl_3$–THF complex;[1685] from $TiCl_4$ and Zn or Mg;[1686] from $TiCl_3$ and $LiAlH_4$;[1687] and from $TiCl_3$ and K or Li;[1688] and with certain compounds prepared from WCl_6 and either lithium, lithium iodide, $LiAlH_4$, or an organolithium[1689] (see Reaction **17-18**). Microwave irradiation has been used to facilitate the coupling.[1690] The reaction has been used to convert dialdehydes and diketones to cycloalkenes.[1691] Rings of 3–16 and 22 members have been closed in this way, for example,[1692]

The same reaction on a keto ester gives a cycloalkanone.[1693]

Indoles have been prepared form *o*-acyl amides with Ti(powder) and Me_3SiCl[1694] or with $TiCl_3$–C_8K.[1695] Benzofurans have been prepared by a closely related reaction.[1696]

Unsymmetrical alkenes can be prepared from a mixture of two ketones in a cross-coupling reaction, if one is in excess.[1697] An aldehyde and a ketone were cross-coupled using $Yb(OTf)_3$, for example.[1698] The mechanism consists of initial coupling of two radical

species to give a 1,2-dioxygen compound (a titanium pinacolate), which is then deoxygenated.[1699]

OS **VII**, 1.

19-78 Acyloin Ester Condensation

43

When carboxylic esters are heated with sodium in refluxing ether or benzene, a bimolecular reduction takes place, and the product is an α-hydroxy ketone (called an acyloin).[1700] The reaction, called the *acyloin ester condensation* (or just *acyloin condensation*),[1701] is quite successful when R is alkyl. Acyloins with long chains have been prepared in this way (e.g., $R = C_{17}H_{35}$), but for high-molecular-weight esters, toluene or xylene is used as the solvent. Modifications to this procedure have been reported, including an ultrasound-promoted acyloin condensation in ether,[1702] which improved the yields of four-, five-, and six-membered rings, and Olah's procedure, which was also done in ether.[1703]

The acyloin condensation has been used with great success, in boiling xylene, to prepare cyclic acyloins from diesters.[1704] The yields are 50–60% for the preparation of 6- and 7-membered rings, 30–40% for 8- and 19-membered, and 60–95% for rings of 10–20 members. Even larger rings have been closed in this manner. Indeed, this is one of the best ways of closing rings of 10 members or more. The reaction has been used to close 4-membered rings,[1705] although this is generally unsuccessful. For larger rings, the presence of double or triple bonds does not interfere.[1706] Even a benzene ring can be present, and many paracyclophane derivatives (**44**) with $n = 9$ or more have been synthesized in this manner.[1707]

Yields in the acyloin condensation can be improved by running the reaction in the presence of chlorotrimethylsilane (Me_3SiCl), in which case the dianion (**43**) is converted to the bis (silyl) enol ether (**45**), which can be isolated and subsequently hydrolyzed to the acyloin with aq acid.[1708] This is now the standard way to conduct the acyloin condensation. Among other things, this method inhibits the *Dieckmann condensation*[1709] (Reaction **16-85**), which otherwise competes with the acyloin condensation when a five-, six-, or seven-membered ring can be closed (note that the ring formed by a *Dieckmann condensation* is

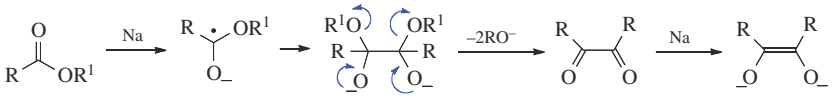
always one carbon atom smaller than that formed by an acyloin condensation of the same substrate). The Me_3SiCl method is especially good for the closing of four-membered rings.[1710]

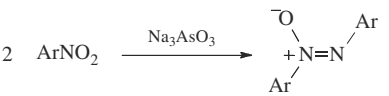


44

45

The mechanism is usually presumed to have a diketone (RCOCOR) as an intermediate,[1711] since small amounts of it are usually isolated as side products, and when it is resistant to reduction (e.g., *t*-Bu−COCO−*t*-Bu), it is the major product. A possible sequence (analogous to that of Reaction **19-76**) is

A large surface area for the Na is usually required for good results in this coupling, consistent with a surface reaction. In order to account for the ready formation of large rings, which means that the two ends of the chain must approach each other even though this is conformationally unfavorable for long chains, it may be postulated that the two ends become attached to nearby sites on the surface[1712] of the Na. Although high dilution techniques are not always necessary, effective stirring (high-speed stirrer at 2000–2500 rpm) is usually required to generate "sodium sand". Highly pure Na gives poorer results because the presence of a small percentage of K is important. Up to 50% potassium (1 : 1 Na/K)[1713] has been used in acyloin condensations.



In a related reaction, aromatic carboxylic acids were condensed to α-diketones (2ArCOOH → ArCOCOAr) on treatment with excess Li in dry THF in the presence of ultrasound.[1714]

The acyloin condensation was used in an ingenious manner to prepare the first reported catenane (see Sec. 3.D).[1715] This synthesis of a catenane produced only a small yield and relied on chance for threading the molecules before ring closure.

Azoxy compounds can be obtained from nitro compounds with certain reducing agents, notably sodium arsenite, sodium ethoxide, NaTeH,[1716] and glucose. The most probable mechanism with most reagents is that one molecule of nitro compound is reduced to a nitroso compound and another to a hydroxylamine (Reaction **19-46**), and these combine (Reaction **12-51**). The combination step is rapid compared to the reduction process.[1717] Nitroso compounds can be reduced to azoxy compounds with triethylphosphite or triphenylphosphine[1718] or with an alkaline aqueous solution of an alcohol.[1719]

OS **II**, 57.

19-80 Reduction of Nitro to Azo Compounds

_N_-De-bisoxygen-coupling

$$2\,ArNO_2 \xrightarrow{LiAlH_4} Ar{-}N{=}N{-}Ar$$

Nitro compounds can be reduced to azo compounds with various reducing agents, of which $LiAlH_4$ and Zn and alkali are the most common. A combination of triethylammonium formate and lead in methanol is also effective.[1720] With many of these reagents, slight differences in conditions can lead either to the azo or azoxy (Reaction **19-79**) compound. By analogy to Reaction **19-79**, this reaction may be looked on as a combination of ArN=O and $ArNH_2$ (**13-24**). However, when the reducing agent was $NaBH_4$,[1721] it was shown that azoxy compounds were intermediates. Nitroso compounds can be reduced to azo compounds with $LiAlH_4$. Dicarborane, with a catalytic amount of acetic acid, reduces aromatic nitro compounds to the amine.[1722]

Nitro compounds can be further reduced to hydrazo compounds with Zn and sodium hydroxide, with hydrazine hydrate and Raney nickel,[1723] or with $LiAlH_4$ mixed with a metal chloride (e.g., $TiCl_4$ or VCl_3).[1724] The reduction has also been accomplished electrochemically.

OS **III**, 103.

G. Reactions in which an Organic Substrate Is Both Oxidized and Reduced

Some reactions that belong in this category have been considered in earlier chapters. Among these are the *Tollens' condensation* (Reaction **16-43**), the benzil–benzilic acid rearrangement (Reaction **18-6**), and the *Wallach rearrangement* (Reaction **18-43**).

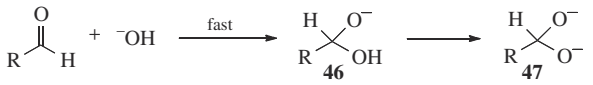
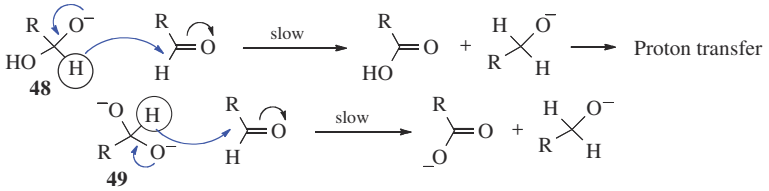
Aromatic aldehydes, and aliphatic ones with no α hydrogen, give the *Cannizzaro reaction* when treated with NaOH or other strong bases.[1725] Reaction with triethylamine and $MgBr_2$ gave a room temperature *Cannizzaro reaction*.[1726] The reaction is mediated by organobases.[1727] In this reaction, one molecule of aldehyde oxidizes another to the acid and is itself reduced to the primary alcohol. Aldehydes with an α hydrogen do not give the reaction, because when these compounds are treated with base, the aldol reaction (**16-34**) is much faster.[1728] Normally, the best yield of acid or alcohol is 50% each, but this can be altered in certain cases. Solvent-free reactions are known.[1729] On the other hand, high yields of alcohol can be obtained from almost any aldehyde by running the reaction in the presence of formaldehyde.[1730] In this case, the formaldehyde reduces the aldehyde to alcohol and is itself oxidized to formic acid. In such a case, where the oxidant aldehyde differs from the reductant aldehyde, the reaction is called the *crossed-Cannizzaro reaction*.[1731] The *Tollens' condensation* (Reaction **16-43**) includes a *crossed-Cannizzaro reaction* as its last step. A *Cannizzaro reaction* with 1,4-dialdehydes (note that α-hydrogen atoms are present here) and a Rh catalyst gives ring closure, for example,[1732]

The product is the lactone derived from the hydroxy acid that would result from a normal *Cannizzaro reaction*. Chiral additives have been used, but with bis(oxazolidine) derivatives, the reaction proceeded with poor enantioselectivity.[1733]



α-Keto aldehydes give internal *Cannizzaro reactions*[1734]:



This product is also obtained on alkaline hydrolysis of compounds of the formula $RCOCHX_2$. Similar reactions have been performed on α-keto acetals[1735] and γ-keto aldehydes.

The mechanism[1736] of the *Cannizzaro reaction*[1737] involves a hydride shift (an example of mechanism type 2, Sec. 19.A). First ^-OH adds to the C=O to give **46**, which may lose a proton in the basic solution to give the diion (**47**).

The strong electron-donating character of O^- greatly facilitates the ability of the aldehyde hydrogen to leave with its electron pair. Of course, this effect is even stronger in **49**. Hydride is transferred to another molecule of aldehyde. The hydride can come from **48** or **49**:

If the hydride ion comes from **48**, the final step is a rapid proton transfer. In the other case, the acid salt is formed directly, and the alkoxide ion acquires a proton from the solvent. Evidence for this mechanism is (1) The reaction can be first order in base and second order in substrate (thus going through **48**) or, at higher base concentrations, second order in each (going through **49**); and (2) when the reaction was run in D_2O, the recovered alcohol contained no α deuterium,[1738] indicating that the hydrogen comes from another equivalent of aldehyde and not from the medium.[1739]

19-82 The Tishchenko Reaction

Tishchenko aldehyde-ester disproportionation

$$2\ \mathrm{ArCHO} \xrightarrow{\mathrm{Al(OEt)_3}} \mathrm{ROOCH_2R}$$

When aldehydes, with or without an α hydrogen, are treated with aluminum ethoxide, one molecule is oxidized and another is reduced, as in Reaction **19-81**, but here they are found as the ester. The process is called the *Tishchenko reaction*.[1740] Crossed-*Tishchenko reactions* are also possible. With more strongly basic alkoxides (e.g., Mg or sodium alkoxides), aldehydes with an a hydrogen give the *aldol reaction*. Treatment of a dialdehyde [e.g., phthalic dicarboxaldehyde (phthalaldehyde) with CaO] leads to a lactone.[1741] Like Reaction **19-81**, this reaction has a mechanism that involves hydride transfer.[1742] The *Tishchenko reaction* can also be catalyzed[1743] by Ru complexes,[1744] organoactinides,[1745] alkaline earth amides,[1746] by Cp_2ZrH_2[1747] and, for aromatic

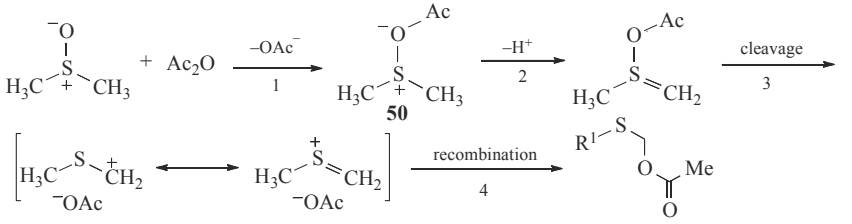
aldehydes, by disodium tetracarbonylferrate [$Na_2Fe(CO)_4$].[1748] Both CaO (noted above) and SrO have been used as catalysts.[1749] A bis(phenylenedioxy) bis(aluminum) catalyst has been used to convert aliphatic aldehydes to the corresponding ester.[1750] The bis Al(O-*i*Pr)$_2$ derivative of catechol has also been used as a catalyst.[1751]

A *Tishchenko–aldol transfer reaction* was reported using β-hydroxy ketones and an aldehydes with an $AlMe_3$ catalyst, giving a monoacyl diol.[1752]

OS **I**, 104.



19-83 The Pummerer Rearrangement[1753]

Pummerer methyl sulfoxide rearrangement

When sulfoxides bearing an α hydrogen are treated with acetic anhydride, the product is an α-acetoxy sulfide. This is one example of *the Pummerer rearrangement*,[1754] in which the sulfur is reduced while an adjacent carbon is oxidized.[1755] The product is readily hydrolyzed (Reaction **10-6**) to the aldehyde (R_2CHO).[1756] Besides acetic anhydride, other anhydrides and acyl halides give similar products. Inorganic acids (e.g., HCl), also give the reaction, and $RSOCH_2R'$ can be converted to $RSCHClR'$ in this way. Sulfoxides can also be converted to α-halo sulfides[1757] by other reagents, including sulfuryl chloride, NBS, and NCS. Enantioselective *Pummerer rearrangements* are known.[1758] Uncatalyzed thermal rearrangements are also known.[1759]

The following 4-step mechanism has been proposed for the reaction between acetic anhydride and DMSO[1760]:

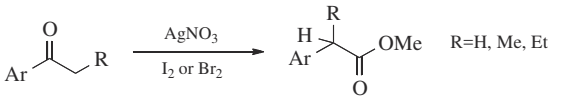
For DMSO and acetic anhydride, step 4 is intermolecular, as shown by ^{18}O isotopic labeling studies.[1761] With other substrates, however, step 4 can be inter- or intramolecular, depending on the structure of the sulfoxide.[1762] Depending on the substrate and reagent, any of the first three steps can be rate determining. In the case of Me_2SO treated with $(F_3CCO)_2O$, the intermediate corresponding to **50**[1763] could be isolated at low temperature, and on warming gave the expected product.[1764] There is also an abundance of other evidence for this mechanism.[1765]

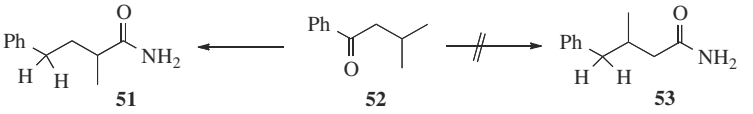
A *sila-Pummerer rearrangement* has been reported.[1766]

19-84 The Willgerodt Reaction



Willgerodt carbonyl transformation

$$ArCOCH_3 \xrightarrow{(NH_4)_2S_x} ArCH_2CONH_2 + ArCH_2COO^-NH_4^+$$



In the *Willgerodt reaction*, a straight- or branched-chain aryl alkyl ketone is converted to the amide and/or the ammonium salt of the acid by heating with ammonium polysulfide.[1767] The carbonyl group of the product is always at the end of the chain. Thus $ArCOCH_2CH_3$ gives the amide and the salt of $ArCH_2CH_2CO_2H$ and $ArCOCH_2CH_2CH_3$ gives derivatives of $ArCH_2CH_2CH_2CO_2H$. However, yields sharply decrease with increasing length of chain. The reaction has also been carried out on vinylic and ethynyl aromatic compounds and on aliphatic ketones, but yields are usually lower in these cases. Unlike the *Pummerer rearrangement* (Reaction **19-83**), which involves transposition of an oxygen from S to C, the *Willgerodt reaction* involves oxygen migration *and* oxidation of the organic species. The use of sulfur and a dry primary or secondary amine (or ammonia), as the reagent is called the *Kindler modification* of the *Willgerodt reaction*.[1768] The product in this case is $Ar(CH_2)_nCSNR_2$,[1769] which can be hydrolyzed to the acid. Particularly good results are obtained with morpholine as the amine. For volatile amines, the HCl salts can be used instead, with NaOAc in DMF at 100 °C.[1770] Dimethylamine has also been used in the form of dimethylammonium dimethylcarbamate (Me_2NCOO^- $Me_2NH_2^+$).[1771] The *Kindler modification* has also been applied to aliphatic ketones.[1772] Thioamides have been prepared from ketones in a base-catalyzed reaction.[1773]

Alkyl aryl ketones can be converted to arylacetic acid derivatives in an entirely different manner. The reaction consists of treatment of the substrate with silver nitrate and I_2 or Br_2.[1774]

The mechanism of the *Willgerodt reaction* is not completely known, but some conceivable mechanisms can be excluded. Thus, one might suppose that the alkyl group becomes completely detached from the ring, and then attacks it with its other end. However, this possibility is ruled out by experiments, such as the following: When isobutyl phenyl ketone (**51**) is subjected to the *Willgerodt reaction*, the product is **52**, not **53**, which would arise if the end carbon of the ketone became bonded to the ring in the product[1775]:

This also excludes a cyclic-intermediate mechanism similar to that of the *Claisen rearrangement* (Reaction **18-33**). Another important fact is that the reaction is successful for singly branched side chains (e.g., **52**), but not for doubly branched side chains, as in $PhCOCMe_3$.[1775] Still another piece of evidence is that compounds oxygenated along the chain give the same products; thus $PhCOCH_2CH_3$, $PhCH_2COMe$, and $PhCH_2CH_2CHO$ all give $PhCH_2CH_2CONH_2$.[1776] All these facts point to a mechanism consisting of consecutive oxidations and reductions along the chain, although just what form these take is not certain. Initial reduction to the hydrocarbon can be ruled out, since alkylbenzenes do not give the reaction. In certain cases, imines[1777] or enamines[1778] have been isolated from primary and secondary amines, respectively, and these have been shown to give the normal products, leading to the suggestion that they may be reaction intermediates.

APPENDIX A

The Literature of Organic Chemistry

All discoveries in the laboratory must be published somewhere if the information is to be made available to the scientific community. A new experimental result that is not published is useless, insofar as it benefits the entire chemical world. Traditionally, the total body of chemical knowledge (called *the literature*) is located on the combined shelves of all the chemical libraries in the world. Nowadays, books remain on library shelves, but many, if not most, chemical journals are available online. As e-books become increasingly available, however, books will be available online or for personal electronic reading devices. Anyone who wishes to learn the answer to a chemical question will access the chemical literature, both books and original articles in journals. The expressions "is known", "has been done", and so on, usually means "has been published". The contents of the scientific literature may appear formidably large, but the process of extracting information from the literature of organic chemistry is usually manageable. Appendix A examines both the print literature of organic chemistry[1] and, within reasonable limits, electronic forms of the literature.

It is quite clear that the literature can be divided into two broad categories: primary sources and secondary sources. A *primary source* publishes the original results of laboratory investigations, usually in scientific journals. Indeed, the two chief kinds of primary source are journals and patents. Books, indexes, and other publications that cover material that has previously been published in primary sources are called *secondary sources*. Electronic search engines that use primary sources as a database are also considered to be secondary sources. It is because of the excellence of the secondary sources in organic chemistry (especially *Chemical Abstracts*, *SciFinder*) that literature searching is comparatively straightforward.

A. PRIMARY SOURCES

A.i. Journals

For well over 100 years, nearly all new work in organic chemistry (except for that disclosed in patents) has been published in journals. There are many journals that publish chemical papers, in many countries and in many languages. Nowadays, a high percentage of the journals are published in English, but not all. Some print papers cover all fields of science; some are restricted to chemistry; some to organic chemistry; and some are still more specialized. As noted above, many journals are now available in electronic form.[2] The actual article is usually offered as an html file, or a PDF file, often with links to the cited references. The vast majority of important papers in "pure" organic chemistry (as opposed to "applied") are published in relatively few journals, perhaps 50 or fewer. The concept of "pure" organic chemistry is not as useful nowadays because organic chemistry is important in many areas, and multidisciplinary research often includes organic chemistry. Literature that is important to an organic chemist is found in journals and patents that focus on bioorganic, organometallic, materials science, polymer science, separation science, medicinal chemistry, pharmaceutical sciences, and medicine to name a few. The reader is therefore cautioned that the journals listed in this section have organic chemistry as their primary focus, but are by no means the only sources of information concerning organic chemistry. The literature is vast and many journals are published weekly and some semimonthly.

Ordinary papers, usually referred to as full papers, usually include full experimental details, either as part of the paper itself or as accompanying supplemental information. Such details are the mainstay of modern research, providing a guide to what has been done, and the experimental details allow one to repeat that work. With the increase in the volume of chemical literature, and especially with the proliferation of electronic journals, and as noted above, many journals now place full experimental details into "Supplemental Information". For journals published by the American Chemical Society, a URL link is provided for each article that contains the supplemental information: experiential details, spectral data, visual reproductions of spectral data, X-ray crystallographic data, and so on. Other publishers offer similar links. Once a paper is accepted, the online version (e.g., American Chemical Society ASAP papers) can be found before the print version or the full electronic version that contains the page numbers appear.

In addition to full papers, there are two other types of publications in which original work is reported: *notes* and *communi*cation*s*. A note is a brief paper, often without a summary (nearly all papers are published with summaries or abstracts prepared by the author). Otherwise, a note is similar to a paper.[3] Some journals specialize in publishing only notes. Communications (also called *letters*) are also brief and are usually without summaries (some journals now publish summaries along with their communications), and there are journals that publish only communications or letters.

Communications differ from notes and papers in three respects:

1. They are brief, not because the work is of small scope, but because they are condensed. Usually they include only the most important experimental details or none at all.

[2] For examples of the contents of an academic electronic library see http://lib.uconn.edu/ or http://www.chem.ox.ac.uk/cheminfo/ejournals.html. Also see eJournal Locator.

[3] In some journals, notes are called "short communications", an unfortunate practice, because they are not communications as that term is defined in this text.

2. They are often of immediate significance. Journals that publish communications make every effort to have them appear as soon as possible after they are received. With modern computer technology, communications can often be published in a matter of weeks.
3. Communications are preliminary reports, and the material in them may be republished as papers at a later date, in contrast to the material in papers and notes, which cannot be republished.

Although chemical publications are published in many languages, the vast majority of important papers in organic chemistry are published in English. For example, six prominent European journals (*Chemische Berichte, Liebigs Annalen der Chemie*, *Bulletin de la Société Chimique de France, Bulletin des Sociétés Chimique Belges, Recueil des Travaux Chimiques des Pays-Bas, and Gazzetta Chimica Italiana*) were discontinued. In their place is the *European Journal of Organic Chemistry, published in English.* Most of the articles published in other languages have summaries printed in English also. Important papers were published in German and French for >200 years, and these are generally not available in translation, so that the organic chemist was required to have at least a reading knowledge of these languages. Before ~1920, more than one-half of the important chemical papers were in these languages. In recent years, however, fewer papers in French or German have appeared without an English translation. Of course, a reading knowledge of French and German (especially German) is critical for the older literature. It must be realized that the original literature is never obsolete. With the rise of China in the scientific community, journals are published in Chinese, and there are journals and important chemical discoveries published in Japanese. Work by Chinese and Japanese scientists regularly appears in English-language journals. Secondary sources become superseded or outdated, but nineteenth century journals with primary literature are found in most chemical libraries and are still consulted. Table A.1 presents a list of important current journals that publish original papers[4] and communications in organic chemistry. Some of them also publish review articles, book reviews, and other material. In 1999, the *Journal of Organic Chemistry* stopped publishing communications, and these are now published in *Organic Letters*.

For some years, the American Chemical Society journals, including *J. Am. Chem. Soc.* and *J. Org. Chem.*, provided supplementary material for some of their papers on microfilm or microfiche. As noted above, this material is now available online, and for older literature from the Microforms and Back Issues Office at the ACS Washington office, either on microfiche, or as a photocopy. These practices have not yet succeeded in substantially reducing the total volume of the world's primary chemical literature since many new journals have appeared, and the yearly page count for most journals has doubled or tripled.

A.ii. Patents

In many countries, including the United States, it is possible to patent a new compound or a new method for making a known compound (either laboratory or industrial procedures). It comes as a surprise to many to learn that a substantial proportion of the patents granted (perhaps 20–30%) have been chemical patents. Chemical patents are part of the chemical literature, and both U.S. and foreign patents were regularly abstracted by *Chemical Abstracts* and now *SciFinder*. In addition to learning about the contents of patents

[4] In Table A.1, notes are counted as papers.

TABLE A.1 A List of the More Important *Current* Journals[a]

No.	Name	Papers or Communications	Issues per Year
1	**Angew**andte **Chem**ie (1887)[b]	C[c]	12
2	**Angew**andte **Chem**ie **Int**ernational **Ed**ition (1962)[b]	C[c]	48
3	**Aust**ralian **J**ournal of **Chem**istry (1948)	P	12
4	**Bioorg**anic **Chem**istry (1971)	P[b]	4
5	**Bioorg**anic & **Med**icinal **Chem**istry **Lett**ers (1991)	C	12
6	**Bull**etin of the **Chem**ical **Soc**iety of **Jap**an (1926)	P	12
7	**Can**adian **J**ournal of **Chem**istry (1929)	P,C	12
8	**Carbohydr**ate **Res**earch (1965)	P,C	22
9	**Chem**istry, a **Eur**opean **Journal** (1995)	P	24
10	**Chem**istry, an **Asian J**ournal (2006)	P	24
11	**Chem**istry and **Ind**ustry **(London)** (1923)	C	24
12	**Chem**istry **Lett**ers (1972)	C	12
13	**Chimia** (1947)	C[b]	12
14	**ChemPlusChem**	New	
15	**Dokl**ady **Chem**istry (1922)[b]	C	12
17.	**Eur**opean **J**ournal of **Org**anic **Chem**istry (1998)	P	12
18	**Helv**etica **Chim**ica **Acta** (1918)	P	8
19	**Heteroat**om **Chem**istry (1990)	P	6
20	**Heterocycles** (1973)	C[b]	12
21	**Ind**ian **J**ournal of **Chem**istry (Section **B**)	P	12
22	**Int**ernational **J**ournal of chemical **Kinet**ics (1969)	P	12
23	**Isr**ael **J**ournal of **Chem**istry (1963)	P[d]	4
23	**J**ournal of the **Am**erican **Chem**ical **Soc**iety (1879)	P,C	52
25	**J**ournal of **Carbohydr**ate **Chem**istry (1981)	P,C	6
26	**J**ournal of **Chem**ical **Res**earch, **Synop**ses (1977)	P	12
27	**Chem**ical **Commun**ications (1965)	C	24
28	**J**ournal of **Comb**inatorial **Chem**istry (2000)	P,C	6
29.	**J**ournal of **Comput**ational **Chem**istry (1979)	P	16
30	**J**ournal of **Fluorine Chem**istry (1971)	P,C	12
31	**J**ournal of **Heterocycl**ic **Chem**istry (1964)	P,C	12
32	**J**ournal of the **Indian** Chemical **Soc**iety (1924)	P	12
33	**J**ournal of **Lipid Res**earch (1959)	P	12
34	**J**ournal of **Med**icinal **Chem**istry (1958)	P,C	12
35	**J**ournal of **Mol**ecular **Struct**ure (1967)	P,C	16
36	**J**ournal of **Organomet**allic **Chem**istry (1963)	P,C	48
37	**J**ournal of **Org**anic **Chem**istry (1936)	P,C	26
38	**J**ournal of **Photochem**istry and **Photobiol**ogy, **A**: Chemistry (1972)	P	12
39	**J**ournal of **Phys**ical **Org**anic **Chem**istry (1988)	P	12
40	**J**ournal of **Poly**mer **Sci**ence Part **A** (1962)	P	24
41	**J**ournal für **Prakt**ische **Chem**ie (1834)	P	6
42	**Macromolecules** (1968)	P,C	26
43	**Liebigs Ann**alen der **Chem**ie (1832)	P	12
44	**Mendeleev Commun**ications (1991)	C	8
45	**Monatsh**efte für **Chem**ie (1870)	P	12
46	**New J**ournal of **Chem**istry (1977)[d]	P	11
47	**Organometallics** (1982)	P,C	12
48	**Org**anic and **Biomol**ecular **Chem**istry (2003)	P	24

49	**Org**anic **Lett**ers (1999)	C	12
50	**Org**anic **Mass Spectrom**etry (1968)	PC	12
51	**Org**anic **Prep**arations and **Proced**ures **Int**ernational (1969)	P[b]	6
52	**Org**anic **Process Res**earch & **Dev**elopment (1997)	P	6
53	**Photochem**istry and **Photobiol**ogy (1962)	P[b]	12
54	**Pol**ish **J**ournal of **Chem**istry (1921)[e]	PC	12
55	**Pure** and **Appl**ied **Chem**istry (1960)	[f]	12
56	**Res**earch on Chemical **Intermed**iates (1973)[g]	P[b]	6
57	**Russ**ian **J**ournal of **Org**anic **Chem**istry (1984)	P,C	12
58	**Sulf**ur **Lett**ers (1982)	C	6
59	**Synlett** (1989)	C[b]	12
60	**Synth**etic **Commun**ications (1971)	C	22
61	**Synthesis** (1969)	P[b]	12
62	**Tetrahedron** (1958)	P[b]	52
63	**Tetrahedron: Asymmetry** (1990)	PC	12
64	**Tetrahedron Lett**ers (1959)	C	52

[a]These journals currently publish original papers in organic chemistry, listed in alphabetical order of *Chemical Abstracts* abbreviations, which are indicated in boldface. Also given are the year of founding, number of issues per year as of 2012, and whether the journal primarily publishes papers (P), communications (C), or both.

[b]See Ref. 5.

[c]See Ref. 6.

[d]See Ref. 7.

[e]See Ref. 8.

[f]See Ref. 9.

[g]See Ref. 10.

from this source, chemists may consult the *Official Gazette* of the U.S. Patent Office, which, published weekly and available in many libraries, lists titles of all patents issued that week. Bound volumes of all U.S. patents are kept in a number of large libraries, including the New York Public Library, which also has an extensive collection of foreign patents. Photocopies of any U.S. patent and most foreign patents were obtained at low cost from the U.S. Patent and Trademark Office, Washington, DC, 20231. Many patents can now be obtained online as well or are available as PDF files. Patents are also available via SciFinder (formerly, CAS online).

Although patents are often very useful to the laboratory chemist, and no literature search is complete that neglects relevant patents, as a rule they are not as reliable as papers. There are two reasons for this finding:

1. It is in the interest of the inventor to claim as much as possible. The patent may show, for example, that a reaction was actually carried with ethanol and with 1-propanol, but will claim all primary alcohols, and perhaps even secondary and tertiary alcohols, glycols, and phenols. An investigator repeating the reaction on an alcohol that the inventor did not use may find that the reaction gives no yield at all.

[5] These journals are available in English translation.
[6] These journals also publish review articles regularly.
[7] Each issue of this journal is devoted to a specific topic.
[8] Before 1978 this journal was called ***Roczniki Chemii***.
[9] *Pure Appl. Chem.* publishes IUPAC reports and lectures given at IUPAC meetings.
[10] Before 1989 this journal was called ***Rev****iews of* ***Chem****ical* ***Intermed****iates*.

In general, it is safest to duplicate the actual examples given, of which most chemical patents contain one or more.

2. Although legally a patent gives an inventor a monopoly, any alleged infringements must be protected in court, and this may cost a good deal of money. Therefore some patents are written so that certain essential details are concealed or entirely omitted. A patent is supposed to be a full disclosure, but patent attorneys are generally skilled in the art of writing patents, and procedures given are not always sufficient to duplicate the results.

Fortunately, the above statements do not apply to all chemical patents: many make full disclosures and claim only what was actually done. It must also be pointed out that it is not always possible to duplicate the work reported in every paper in a journal due to the use of proprietary catalysts or equipment not available to the public. It is not uncommon to literally purchase the world's supply of a key ingredient. Note, however, that some work is not published or patented but rather maintained within the company as a trade secret. Such work is not, of course, available to the public.

B. SECONDARY SOURCES

Journal articles and patents contain virtually all of the original work in organic chemistry. However, if this were all, if there were no indexes, abstracts, review articles, and other secondary sources, the literature would be unusable, because it is so vast that no one could hope to find anything in particular. Fortunately, the secondary sources are excellent. There are various kinds and the classification shown here is somewhat arbitrary.

B.i. Listings of Titles

The profusion of original papers is so great that publications that list the titles of current papers find much use. Such lists are primarily methods of alerting the chemist to useful papers published in journals that are not normally read. This approach using print versions containing lists or journals and articles is used sparingly nowadays. Most journals are available online with useful search engines, and most have the original papers, with supplemental material, as html and PDF[11] documents. The PDF document can be downloaded to the searcher's desktop, sometimes for a fee, shipped to other scientists electronically, and is most convenient. *Chemical Abstracts* was available online as *CAS OnLine*, but this service has been supplanted by *SciFinder* (see Appendix A.D.iii). University libraries and companies pay the appropriate fees, so access to the journals is usually quite easy if one is affiliated with these organizations. Search engines allow one to quickly scan an enormous amount of literature from office or home. In addition, most browsers have online searching capabilities via various search engines, and simply typing in an author, a topic, a chemical, or a few keywords can lead to important articles or information. "Google® searching"[12] is commonly employed for a "quick and dirty" search, but one is strongly urged to use one of the established scientific search engines for a proper search.

[11] Adobe Acrobat files.
[12] Available at www.google.com/

The more important online technology will be discussed below. However, some other resources[13] include Specialty Citation Indexes Science Citation Index Expanded™, Web of Science®, Science Citation Index®, ISI ProceedingsSM, Reaction Citation Index™, and the Derwent Innovations IndexSM. The discussion will begin with the older print versions for chemical searches.

A print-version "title" publication covering the whole of chemistry is *Current Contents Physical, Chemical & Earth Sciences*,[14] which began in 1967 and appears weekly, contains the contents pages of all issues of about 800 journals in chemistry, physics, earth sciences, mathematics, and allied sciences. Each issue contains an index of important words taken from the titles of the papers listed in that issue, and an author index, which, however, lists only the first-named author of each paper. The author's address is also given, so that one may write for reprints. An online service is available called *Current Contents Connect*® is a multidisciplinary Web resource providing access to complete bibliographic information from >8000 of the world's leading scholarly journals and >2000 books.[15]

Chemical titles is a similar publication produced by the Chemical Abstracts Service (CAS). SciFinder described below allows one to search a variety of databases, including journal titles.

B.ii. Abstracts

Listings of titles are valuable, as far as they go, but they do not tell what is in the paper, beyond the implications carried by the titles. Most current journals contain a graphic abstract, as well as a title and a brief print description of the research. The graphical abstract is extremely useful for scanning the literature presented in a journal, and both the print and graphical abstracts are available online for most journals.

From the earliest days of organic chemistry, abstracts of papers have been widely available, often as sections of journals whose principal interests lay elsewhere.[16] At the present time there are only two publications entirely devoted to abstracts covering the whole field of chemistry. One of these, *Referativnyi Zhurnal, Khimiya*, which began in 1953, is published in Russian and is chiefly of interest to Russian-speaking chemists. The other is *Chemical Abstracts*, which was published until 2010. Abstracts are now available online via *SciFinder*. Although out of print, knowledge of Chemical Abstracts is important to properly do a literature search that includes older literature. *Chemical Abstracts* appeared weekly and printed abstracts in English of virtually every paper containing original work in pure or applied chemistry published anywhere in the world.[17] More than 18,000 journals were covered, in many languages. In addition, *CA* published abstracts of every patent of chemical interest from 18 countries, as well as many patents from additional countries. The abstracts currently appeared in 80 sections, with sections 21–34 devoted to organic chemistry, under such headings as Alicyclic Compounds, Alkaloids, Physical Organic Chemistry, Heterocyclic Compounds (One Heteroatom),

[13] See http://scientific.thomson.com/products/categories/citation/

[14] Title pages of organic chemistry journals are also carried by *Current Contents Life Sciences*, which is a similar publication covering biochemistry and medicine.

[15] Available at http://scientific.thomson.com/products/ccc/

[16] For example, *Chem. Ind. (London)* publishes abstracts of papers that appear in other journals. In the past, journals, such as *J. Am. Chem. Soc., J. Chem. Soc.,* and *Ber*. also did so.

[17] For a guide to the use of *CA*, see Schulz, H. *From CA to CAS ONLINE*; VCH: NY, 1988.

and so on. Each abstract of a paper had a heading that gave (1) the abstract number;[18] (2) the title of the paper; (3) the authors' names as given in the paper; (4) the authors' address; (5) the abbreviated name of the journal (see Table A.1);[19] (6) the year, volume, issue, and page numbers; and (7) the language of the paper. In earlier years *CA* gave the language only if it differed from the language of the journal title. Abstracts of patents showed the abstract number, title, inventor and company (if any), patent number, patent class number, date patent issued, country of priority, patent application number, date patent applied for, and number of pages in the patent. The body of the abstract contained a concise summary of the information in the paper. For many common journals, the author's summary (if there is one) was used in *CA* as it appeared in the original paper, with perhaps some editing and additional information. Each issue of *CA* contained an author index, a patent index, and an index of keywords taken from the titles and the texts or contexts of the abstracts. The patent index listed all patents in order of number. The same compound or method is often patented in several countries. *Chemical Abstracts* abstracted only the first patent, but listed the patent numbers of the duplicated patents in the patent index along with all previous patent numbers that correspond to it. Before 1981 there were separate Patent Number Indexes and Patent Concordances (the latter began in 1963).

At the end of each section of *CA* a list of cross-references to related papers in other sections is given.

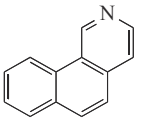
Chemical Abstracts is useful as a repository of chemical information, a place for finding out what was done in the past. This value stems from the excellent indexes, which enable the chemist in most cases to ascertain quickly where information is located. From the time of its founding in 1907 until 1961, *CA* published annual indexes. After 1962 there were two volumes published each year, and a separate index is issued for each volume. Each volume contained an index of subjects, authors, formulas, and patent numbers. Beginning in 1972, the subject index was issued in two parts, a chemical substance index and a general subject index, which included all entries that are not the names of single chemical substances. However, the indexes to each volume were essentially superseded by each collective index. The first collective indexes were 10-year (decennial) indexes, but the volume of information made 5-year indexes necessary since 1956. Collective indexes so far published are shown in Table A.2.

As noted above, the print form of Chemical Abstracts has been superseded by SciFinder (see Appendix A.D.iii)

Beginning with the Eighth collective index period, *CA* has published an *Index Guide*. This publication gave structural formulas and/or alternate names for thousands of compounds, as well as many other cross-references. It was designed to help the user efficiently and rapidly to find *CA* references to subjects of interest in the general subject, formula, and chemical substance indexes. Each collective index contained its own *Index Guide*. The *Index Guide* was necessary because the *CA* general subject index was a "controlled index", meaning it restricted its entries only to certain terms.

For example, anyone looking for the term "refraction" in the printed general subject index will not find it. The *Index Guide* included this term, and directed the reader to "Electromagnetic wave, refraction of", "Sound and ultrasound, refraction of", and other terms, all of which were found in the general subject index. Similarly, the chemical substance index usually listed a compound only under one name - the approved *CA* name.

[18] Began in 1967. See Appendix A.B.ii.



[19] These abbreviations are changed from time to time. Therefore the reader may notice inconsistencies.

TABLE A.2 *CA* Collective Indexes So Far Published

Collective Index	Subject General Subject	Chemical Substance	Author	Formula	Patents
1	1907–1916		1907–1916		
2	1917–1926		1917–1926		1907–1936

Trivial and other names were found in the *Index Guide*. For example, the term "methyl carbonate" is not in the chemical substance index, but the *Index Guide* does have this term, and directs the reader to the chemical substance index under the headings "carbonic acid, esters, dimethyl ester" (for Me_2CO_3) and "carbonic acid, esters, monomethyl ester" (for $MeHCO_3$). Furthermore, the *Index Guide* gives terms related to the chosen term, helping users to broaden a search. For example, one who looks for "Atomic orbital" in the *Index Guide* will find the terms "Energy Level", "Molecular orbital", "Atomic integral", and "Exchange, quantum mechanical, integrals for", all of which are controlled index terms.

Each index (annual, semiannual, or collective) also provided an index of ring systems. This valuable index enables the user to ascertain immediately if any ring system appears in the corresponding subject or chemical substance index and under what names. For example, someone wishing to determine whether any compounds

Benz(*h*)isoquinoline

containing the benz(*h*)isoquinoline ring system are reported in the 1982–1986 collective index would locate, under the heading "3-ring systems", the listing **6**, **6**, **6** (since the compound has three rings of six-members each), and would find the sublisting C_5N–C_6–C_6 (since one ring contains five carbons and a nitrogen while the others are all-carbon), under which is listed the name benz(*h*)isoquinoline, as well as the names of 30 other systems C_5N–C_6–C_6. A search of the chemical substance index under these names will give all references to these ring systems that appeared in *CA* from 1982 to 1986.

Nowadays, the drawing tools of SciFinder (sec. Appendix A.D.iii) are used to draw this structure, and then perform the search.

Before 1967, *CA* used a two-column page, with each column separately numbered. A row of letters from *a* to *h* appeared down the center of the page for the guidance of the user. Thus an entry 7337*b* refers to the *b* section of column 7337. In early years, superscript numbers (e.g., 4327^5) were used in a similar manner. In very early years, these numbers were not printed on the page at all, though they are given in the decennial indexes, so that the user must mentally divide the page into nine parts. Beginning with 1967, abstracts are individually numbered and column numbers are discarded. Therefore, beginning with 1967, index entries give abstract number rather than column number. The abstract numbers are followed by a letter that serves as a check character to prevent miscopying errors in computer handling. To use the *CA* general subject, chemical substance, and formula indexes intelligently requires practice, and the student should become familiar with representative volumes of these indexes and with the introductory sections to them, as well as with the *Index Guides*.

In the *CA* formula indexes, formulas were listed in order of (1) number of carbon atoms; (2) number of hydrogen atoms; (3) other elements in alphabetic order. Thus, all C_3 compounds are listed before any C_4 compound; all C_5H_7 compounds before any C_5H_8 compound; $C_7H_{11}Br$ before $C_7H_{11}N$; $C_9H_6N_4S$ before C_9H_6O, and so on. Deuterium and tritium are represented by D and T and treated alphabetically (e.g., C_2H_5DO after C_2H_5Cl and before C_2H_5F or C_2H_6).

Since 1965, *CA* has assigned a Registry Number[20] to each unique chemical substance. This is a number of the form [766-51-8] that remains invariant, no matter what names are used in the literature. More than 64 million numbers have already been assigned and thousands are added each week. Registry Numbers are primarily for computer use, but chemical suppliers use CAS registry numbers to identify chemicals that are available for sale.

There were a number of earlier abstracting publications now defunct. The most important are *Chemisches Zentralblatt* and *British Abstracts*. These publications are still valuable because they began before *CA* and can therefore supply abstracts for papers that appeared before 1907. Furthermore, even for papers published after 1907, *Zentralblatt* and *British Abstracts* are often more detailed. *Zentralblatt* was published, under various names, from 1830 to 1969.[21] *British Abstracts* was a separate publication from 1926 to 1953, but earlier abstracts from this source are available in the *Journal of the Chemical Society* from 1871 to 1925.

B.iii. Beilstein

This publication has been so important to organic chemistry that it deserves a section by itself. Beilstein's *Handbuch der Organischen Chemie*, usually referred to as *Beilstein*, lists all the known organic compounds reported in the literature during its period of coverage. The print version will be described first, as it is particularly important for older literature.

For each compound in *Beilstein*, the following data are given: all names; the molecular formula; the structural formula; all methods of preparation (briefly, e.g., "by refluxing 1-butanol with NaBr and sulfuric acid"); physical constants (melting point, refractive index, etc.); other physical properties; chemical properties including reactions; occurrence in nature (i.e., which species it was isolated from); biological properties, if any; derivatives

[20] See http://www.cas.org/expertise/cascontent/registry/regsys.html

[21] An "obituary" of *Zentralblatt* by Weiske, C., gives its history and statistical data about its abstracts and indexes, and was published in the April 1973 issue of *Chem. Ber.* (pp. I–XVI).

with melting points; analytical data, and any other information that has been reported in the literature.[22] Equally important, for every piece of information, a reference is given to the original literature. Furthermore, the data in Beilstein have been critically evaluated. That is, all information is carefully researched and documented, and duplicate and erroneous results are eliminated. Some compounds are discussed in two or three lines and others require several pages.

The print editions are invaluable for searching older literature, but even today provide valuable data for many compounds used every day. A discussion of using *Beilstein* is therefore essential.

The first three editions of Beilstein are obsolete. The fourth edition (*vierte Auflage*) covers the literature from its beginnings through 1909. This edition, called *das Hauptwerk*, consists of 27 volumes. The compounds are arranged in order of a system too elaborate to discuss fully here.[23] The compounds are divided into three divisions that are further subdivided into "systems":

Division	Volumes	System Numbers
I. Acyclic Compounds	1–4	1–499
II Carbocyclic Compounds	5–16	450–2359
III. Heterocyclic Compounds	17–27	2360–4720

Das Hauptwerk is still the basis of Beilstein and has not been superseded. The later literature is covered by supplements that have been arranged to parallel *das Hauptwerk*. The same system is used, so that the compounds are treated in the same order. The first supplement (*erstes Ergänzungswerk*) covers 1910–1919; the second supplement (*zweites Ergänzungwerk*) covers 1920–1929; the third supplement (*drittes Ergänzungswerk*) covers 1930–1949; the fourth supplement (*viertes Ergänzungswerk*) covers 1950–1959, and the fifth supplement covers 1960–1979. Like *das Hauptwerk*, each supplement contains 27 volumes,[24] except that supplements 3 and 4 are combined for Vols. 17–27, so that for these volumes the combined third and fourth supplement covers the years 1930–1959. Each supplement has been divided into volumes in the same way as *das Hauptwerk*, and, for example, compounds found in Vol. 3, system number 199 of *das Hauptwerk* will also be found in Vol. 3, system number 199 of each supplement. To make cross-referencing even easier, each supplement gives, for each compound, the page numbers at which the same compound can be found in the earlier books. Thus, on page 554 of Vol. 6 of the fourth supplement, under the listing phenetole are found the symbols (H 140; E I 80; E II 142; E III 545) indicating that earlier information on phenetole is given on page 140 of Vol. 6 of *das Hauptwerk*, on page 80 of the first, page 142 of the second, and

[22] For a discussion of how data are processed for inclusion in Beilstein, see Luckenbach, R.; Ecker, R.; Sunkel, J. *Angew. Chem. Int. Ed. Engl.* ***1981****, 20,* 841 [*Angew. Chem. 93*, 876].

[23] For descriptions of the Beilstein system and directions for using it, see Sunkel, J.; Hoffmann, E.; Luckenbach, R. *J. Chem. Educ.* ***1981****, 58*, 982; Luckenbach, R. *CHEMTECH* ***1979***, 612. The Beilstein Institute has also published two English language guides to the system. One, available free, is *How to Use Beilstein*, Beilstein Institute, Frankfurt/Main, ***1979***. The other is by Weissbach, O. *A Manual for the Use of Beilstein's Handbuch der Organischen Chemie*, Springer, NY, ***1976***. An older work, which many students will find easier to follow, is by Huntress, E.H. *A Brief Introduction to the Use of Beilstein's Handbuch der Organischen Chemie,* 2nd ed., Wiley, NY, ***1938***.

[24] In some cases, to keep the system parallel and to avoid books that are too big or too small, volumes are issued in two or more parts, and, in other cases, two volumes are bound as one.

page 545 of the third supplement. Furthermore, each page of the supplements contains, at the top center, the corresponding page numbers of *das Hauptwerk*. Since the same systematic order is followed in all six series, location of a compound in any one series gives its location in the other five. If a compound is found, for example, in Vol. 5 of *das Hauptwerk*, one has but to note the page number and scan Vol. 5 of each supplement until that number appears in the top center of the page (the same number often covers several pages). Of course, many compounds are found in only one, two, three, four, or five of the series, since no work may have been published on that compound during a particular period covered.

From *das Hauptwerk* to the fourth supplement, Beilstein is in German, but it is not difficult to read since most of the words are the names of compounds (a Beilstein German–English Dictionary, available free from the publisher, is in many libraries). For the fifth supplement (covering 1960–1979), which is in English, publication of Division III began before the earlier divisions. Volumes 17–22 (totaling 70 separate parts exclusive of index volumes) of this supplement have been published, as well as a combined index for volumes 17–19. This index covers only the fifth supplement. The subject portion of this index, which lists compound names only, gives these names in English.

Volumes 28 and 29 of Beilstein are subject and formula indexes, respectively. The most recent complete edition of these volumes is part of the second supplement and covers only *das Hauptwerk* and the first two supplements (though complete indexes covering *das Hauptwerk* and the first four supplements have been announced to appear in the next few years). For Vol. 1, there is a cumulative subject and a cumulative formula index, which combine *das Hauptwerk* and the first four supplements.[25] Similar index volumes, covering all four supplements, have been issued for the other volumes, 2–27. Some of these are combined (e.g., 2–3, 12–14, and 23–25). For English-speaking chemists (and probably for many German-speaking chemists) the formula indexes are more convenient. Of course (except for the fifth supplement indexes), one must still know some German, because most formula listings contain the names of many isomers. If a compound is found only in *das Hauptwerk*, the index listing is merely the volume and page numbers (e.g., **1**, 501). Roman numbers are used to indicate the supplements (e.g., **26**, 15, I 5, **II** 7). Thus the subject and formula indexes lead at once to locations in *das Hauptwerk* and the first four supplements. The Beilstein formula indexes are constructed the same way as the *CA* indexes (Appendix A.B.ii).

There is also a fourth division of Beilstein (systems 4721–4877) that covers natural products of uncertain structure: rubbers, sugars, and so on. These are treated in Vols. 30 and 31, which do not go beyond 1935 and that are covered in the collective indexes. These volumes will not be updated. All such compounds are now included in the regular Beilstein volumes.

In recent years, Beilstein was available online, with the useful search engine *CrossFire*. However, this database is now incorporated into *Reaxys (see Appendix A.D.vi)*.

B.iv. Tables of Information

In addition to Beilstein, there are many other print reference works in organic chemistry that are essentially compilations of data. These books are very useful and often save the

[25] Most page number entries in the combined indexes contain a letter (e.g., $CHBr_2Cl$ 67f, **II** 33a, **III** 87d, **IV**, 81). These letters tell where on the page to find the compound and are useful because the names given in the index are not necessarily those used in the earlier series. The letter "a" means the compound is the first on its page, "b" is the second, and so on. No letters are given for the fourth supplement.

research worker a great deal of time. In this section, we discuss some of the more important of such works.

1. The sixth edition of *Heilbron's Dictionary of Organic Compounds*, J. Buckingham, Ed., 9 vols., Chapman and Hall, London, ***1996***, contains brief listings of >150,000 organic compounds, giving names, structural formulas, physical properties, and derivatives, with references. For many entries, additional data concerning occurrence, biological activity, and toxicity hazard information are also given. The arrangement is alphabetical. The dictionary contains indexes of names, formulas, heteroatoms, and *CA* Registry Numbers. Annual supplements, with cumulative indexes, have appeared since 1983. A similar work, devoted to organometallic compounds, is the 2nd edition of the *Dictionary of Organometallic Compounds*, 6 vols. in its 5th supplement, published by Chapman and Hall in ***1989***. Another, *Dictionary of Steroids*, 2 vols., 1991, is also published by Chapman and Hall.
2. A multivolume compendium of physical data is *Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik, und Technik, 6th ed.,* by H. Landolt and R. Börnstein, Springer, Berlin, 1950. There is also a "New Series", for which the volumes are given the English title *Numerical Data and Functional Relationships in Science and Technology*, as well as the German title. This compendium, which is not yet complete, lists a great deal of data, some of which are of interest to organic chemists (e.g., indexes of refraction, heats of combustion, optical rotations, and spectral data). Literature references are given for all data.
3. *The Handbook of Chemistry and Physics*, CRC Press, Boca Raton, FL (called the "rubber handbook"), which is revised annually (92nd ed., 2011–2012), is a valuable repository of data quickly found. For organic chemists an important table is *Physical Constants of Organic Compounds*, which lists names, formulas, color, solubility, and physical properties of thousands of compounds. However, there are many other useful tables. A similar work is *Lange's Handbook of Chemistry*, 16th ed., McGraw-Hill, New York, 2004. Another such handbook, but restricted to data of interest to organic chemists, is *Dean's Handbook of Organic Chemistry, 2nd ed.,* McGraw-Hill, New York, 2003. This book also contains a long table of *Physical Constants of Organic Compounds*, and has much other information including tables of thermodynamic properties, spectral peaks, pK_a values, bond distances, and dipole moments.
4. A list of most of the known natural compounds (e.g., terpenes, alkaloids, carbohydrates) to which structures have been assigned, along with structural formulas, melting points, optical rotations, and references, is provided in T.K. Devon and A.J. Scott, *Handbook of Naturally Occurring Compounds*, 3 vols., Academic Press, New York, ***1972***.
5. R.R. Dreisbach, *Physical Properties of Chemical Compounds*, Advances in Chemistry Series Nos. 15, 22, 29, American Chemical Society, Washington, 1955–1961 lists many physical properties of >1000 organic compounds.
6. Physical properties of thousands of organometallic compounds, with references, are collected in five large compendia: the *Dictionary of Organometallic Compounds*, mentioned under item 1, above; M. Dub, *Organometallic Compounds, 2nd ed*., 3 vols. with supplements and index, Springer, New York, 1966–1975; N. Hagihara, M. Kumada, and R. Okawara, *Handbook of Organometallic Compounds*,

W.A. Benjamin, New York, ***1968***; and H.C. Kaufman, *Handbook of Organometallic Compounds*, Van Nostrand, Princeton, NJ, ***1961***; *Comprehensive Organometallic Chemistry II*, 14 vols, Pergamon, 1995.

7. The *Merck Index, 14th ed.*, Merck and Company, Rahway, NJ, ***2006*** is a good source of information about chemicals of medicinal importance. Many drugs are given three types of name: chemical *name* (which is the name an organic chemist would give it; of course, there may well be more than one); *generic name*, which must be placed on all containers of the drug; and *trade names,* which are different for each company that markets the drug. For example, the generic name for 1-(4-chlorobenzhydryl)-4-methylpiperazine is chlorcyclazine. Among the trade names for this drug, which is an antihistamine, are Trihistan, Perazyl, and Alergicide. The *Merck Index* is especially valuable because it gives all known names of all three types for each compound and the names are cross-indexed. Also given, for each compound, are the structural formula, *CA* preferred name and Registry Number, physical properties, medicinal and other uses, toxicity indications, and references to methods of synthesis. There are indexes of formulas and Registry Numbers, and miscellaneous tables. The "Merck Index" also includes a lengthy list of organic name reactions, with references.
8. There are two publications that list properties of azeotropic mixtures. J. Timmermans, *The Physico-chemical Constants of Binary Systems in Concentrated Solutions,* 4 vols., Interscience, New York, ***1959–1960***, is by far the more comprehensive. The other is *Azeotropic Data*, 2 vols., Advances in Chemistry Series No. 6 and No. 35, American chemical Society, Washington, ***1952***, ***1962***.
9. Thousands of dipole moments, with references, are collected in V.A.L. McClellan, *Tables of Experimental Dipole Moments, Vol. 1*, W.H. Freeman, San Francisco, CA, ***1963***; *Vol. 2*, Rahara Enterprises, El Cerrita, CA, ***1974***.
10. *Tables of Interatomic Distances and Configurations in Molecules and Ions*, London Chemical Society Special publication no. 11, ***1958***, and its supplement, Special publication no. 18, ***1965***, include bond distances and angles for hundreds of compounds, along with references.
11. The *Ring Systems Handbook*, published in 1988 by the chemical Abstracts Service, provides the names and formulas of ring and cage systems that have been published in *CA*. The ring systems are listed under a system essentially the same as that used for the *CA* index of ring systems (sec. Appendix A.B.i, A.B.ii). Each entry gives the *CA* index name and Registry Number for that ring system. In many cases a *CA* reference is also given. There is a separate Formula Index (for the parent ring systems) and a *Ring Name Index*. Cumulative supplements are issued twice a year. The *Ring Systems Handbook* supersedes earlier publications called *The Parent Compound Handbook* and *The Ring Index*.
12. The Sadtler Research Laboratories published large collections of IR, UV, NMR, and other spectra, in loose-leaf form. Indexes are available.
13. Infrared, UV, NMR, Raman, and mass spectral data, as well as melting-point, boiling-point, solubility, density, and other data for >30,000 organic compounds are collected in the *CRC Handbook of Data on Organic Compounds, 2nd ed.,* 9 vols., CRC Press, Boca Raton, FL, 1988, edited by R.C. Weast and J.G. Grasselli. It differs from the Sadtler collection in that the data are given in tabular form (lists of peaks)

rather than reproduction of the actual spectra, but this book has the advantage that all the spectral and physical data for a given compound appear at one place. References are given to the Sadtler and other collections of spectra. Volumes 7–9 contain indexes of spectral peaks for IR, UV, NMR, ^{13}C NMR, mass, and Raman spectra, as well as indexes of other names, molecular formulas, molecular weights, and physical constants. Annual updates began appearing in 1990 (the first one is called volume 10).

14. The *Aldrich Library of Infrared Spectra, 3rd ed.*, Aldrich Chemical Company, Milwaukee, WI, ***1981***, by Pouchert contains >12,000 IR spectra so arranged that the user could readily see the change that takes place in a given spectrum when a slight change is made in the structure of a molecule. The same company also publishes the *Aldrich Library of FT-IR Spectra* and the *Aldrich Library of NMR Spectra*, both also by C. Pouchert. A similar volume, which has IR and Raman spectra of ∼1000 compounds, is *Raman/Infrared Atlas of Organic Compounds, 2nd ed.,* VCH, New York, ***1989***, by B. Schrader.
15. An extensive list of visible and uv peaks is given in *Organic Electronic Spectral Data,* Wiley, New York. Twenty-six volumes have appeared so far, covering the literature through 1984.
16. A collection of 500 ^{13}C NMR spectra is found in L.F. Johnson and W.C. Jankowski, *Carbon-13 NMR Spectra*, Wiley, New York, ***1972***.

C. REVIEWS

A review article is an intensive survey of a rather narrow field. For example, the titles of some recent reviews are "Metathesis of Alkanes and Related Reactions"[26], "Potassium Organotrifluoroborates: New Perspectives in Organic Synthesis"[27], and "Asymmetric Addition of Allylic Nucleophiles to Imino Compounds".[28] A good review article is of enormous value, because it is a thorough survey of all the work done in the field under discussion. Review articles are printed in review journals and in certain books. The most important review journals in organic chemistry (though most are not exclusively devoted to organic chemistry) are shown in Table A.3. Some of the journals listed in Table A.1, for example, *Chemical Reviews, Accounts of Chemical Research, and Synlett, Tetrahedron, Synthesis, Organic Preparations and Procedures International,* and *J. Organomet. Chem.* also publish occasional review articles. As with other journals, journals that contain reviews are available online.

There are several open-ended serial publications that are similar in content to the review journals but are published irregularly (seldom more often than once a year) and are hardbound. Some of these publish reviews in all fields of chemistry; some cover only organic chemistry; some specialize further. The coverage is indicated by the titles. Table A.4 shows some of the more important such publications, with *CA* abbreviations.

Another publication is the *Index of Reviews in Organic Chemistry*, complied by Lewis, Chemical Society, London, a classified listing of review articles. The first volume, published in 1971, lists reviews from ∼1960 (in some cases much earlier) to ∼1970 in alphabetical

order of topic. Thus four reviews are listed under "Knoevenagel condensation", five under "Inclusion compounds", and one under "Vinyl ketones". There is no index. A second volume (1977) covers the literature to 1976. Annual or biannual supplements appeared from 1979 until the publication was terminated in 1985. Classified lists of review articles on organometallic chemistry are found in articles by Smith and Walton[31] and by Bruce.[32] A similar list for heterocyclic chemistry is found in articles by A. Katritzky and others.[33] See also the discussion of the *Index of Scientific Reviews* in Appendix A.D.iv.

C.i. Annual Reviews

The review articles discussed in Table A.3 are each devoted to a narrow topic covering the work done in that area over a period of years. An annual review is a publication that covers a broad area but limits the period covered, usually to 1 or 2 years.

1. The oldest annual review publication still publishing is *Annual Reports on the Progress of Chemistry*, published by the Royal Society of Chemistry (formerly the chemical Society), which began in 1905 and which covers the whole field of chemistry. Since 1967 it has been divided into sections. Organic chemistry is found in Section B.
2. Because the number of papers in chemistry has become so large, the Royal Society of Chemistry publishes annual-review-type volumes of smaller scope, called *Specialist Periodical Reports*. Among those of interest to organic chemists are *Carbohydrate Chemistry* (Vol. 22 covers 1988); *Photochemistry* (Vol. 21 covers 1988–1989); and *General and Synthetic Methods* (Vol. 12 covers 1987).
3. *Organic Reaction Mechanisms*, published by Wiley, New York, is an annual survey that covers the latest developments in the field of mechanisms. The first volume, covering 1965, appeared in 1966.
4. There are two annual reviews devoted to progress in organic synthesis. Theilheimer, *Synthetic Methods of Organic Chemistry*, S. Karger, Verlag, Basel, is an annual compilation, beginning in 1946, of new methods for the synthesis of organic compounds, arranged according to a system based on bond closing and bond breaking reactions. Equations, brief procedures, yields, and literature references are given. Volume 44 was issued in 1990. Volumes 3 and 4 are available only in

[31] Smith, J.D.; Walton, D.R.M. *Adv. Organomet. Chem.* ***1975****, 13,* 453.
[32] Bruce, M.I. *Adv. Organomet. Chem.* ***1972****, 10,* 273, ***1973****, 11,* 447, ***1974****, 12,* 380.
[33] Belen'kii, L.I. *Adv. Heterocycl. Chem.* ***1988****, 44,* 269; Katritzky, A.R.; Jones, P.M. *Adv. Heterocycl. Chem.* ***1979****, 25,* 303; Katritzky, A.R.; Weeds, S.M. *Adv. Heterocycl. Chem.* ***1966****, 7*, 225.

German, but all the rest are in English. There is an index to each volume. Cumulative indexes appear in every fifth volume. Beginning with vol. 8, each volume includes a short summary of trends in synthetic organic chemistry. A more recent series is *Annual Reports in Organic Synthesis,* Academic Press, New York, which has covered the literature of each year since 1970. Equations are listed with yields and references according to a fairly simple system.

C.ii. Awareness Services

Besides the annual reviews and the title and abstract services previously mentioned, there exist a number of publications designed to keep readers aware of new developments in organic chemistry or in specific areas of it.

1. *Chemtracts: Organic Chemistry* is a bimonthly Periodical, begun in 1988, that prints abstracts of certain recently published papers (those that the editors consider most important), with commentaries on these papers by distinguished organic chemists. Important current research in bioorganic, organometallic, synthesis, physical-organic and theoretical chemistry, and pharmaceutical/medicinal chemistry is covered in each issue, giving readers updates on the newest trends and developments in organic chemistry by summarizing and commenting on current and past research.
2. The Institute for Scientific Information (ISI), besides publishing *Current Contents* (sec. Appendix A.B.i) and the *Science Citation Index* (sec. Appendix A.B.i), also publishes *Index Chemicus* (formerly called *Current Abstracts of Chemistry and Index Chemicus*). This publication, begun in 1960 and appearing weekly, is devoted to printing structural formulas of all new compounds appearing in >100 journals, along with equations to show how they were synthesized and an author's summary of the work. Each issue contains five indexes: author, journal, biological activity, labeled compounds, and intermediates that were not isolated. These indexes are cumulated annually.
3. Theilheimer and the *Annual Reports on Organic Synthesis*, mentioned in the previous section, list new synthetic methods once a year. There are several publications that do this monthly. Among these are *Current Chemical Reactions* (begun in 1979 and published by ISI), *Journal of Synthetic Methods* (begun in 1975 and published by Derwent publications), and *Methods in Organic Synthesis*, begun in 1984 and published by the Royal Society of Chemistry. *Methods in Organic Synthesis* also lists books and review articles pertaining to organic synthesis.
4. *Natural Product Updates,* a monthly publication begun in 1987 and published by the Royal Society of Chemistry, lists recent results in the chemistry of natural products, along with structural formulas. It covers new compounds, structure determinations, new properties and total syntheses, among other topics.

C.iii. General Treatises

There are a number of large-scale multivolume treatises that cover the whole field of organic chemistry or large areas of it.

1. *Rodd's Chemistry of Carbon Compounds*, edited by S. Coffey, Elsevier, Amsterdam, is a treatise consisting of five main volumes, each of which contains several

parts. Publication began in 1964 and is not yet complete. The organization is not greatly different from most textbooks, but the coverage is much broader and deeper. Supplements to many of the volumes have appeared. An earlier edition, called *Chemistry of Carbon Compounds,* edited by E.H. Rodd, was published in 10 parts from 1951 to 1962.

2. Houben–Weyl's *Methoden der Organischen Chemie*, Georg Thieme Verlag, Stuttgart, is a major treatise in German devoted to laboratory methods. The fourth edition, which was begun in 1952 and consists of 20 volumes, most of them in several parts, is edited by E. Muller. The series includes supplementary volumes. The first four volumes contain general laboratory methods, analytical methods, physical methods, and general chemical methods. The later volumes are devoted to the synthesis of specific types of compounds (hydrocarbons, oxygen compounds, nitrogen compounds, etc.). Beginning in 1990 parts of the series have appeared in English.
3. *Comprehensive Organic Chemistry*, Pergamon, Elmsford, NY, ***1979***, is a six-volume treatise on the synthesis and reactions of organic compounds. The first three volumes cover the various functional groups, Vol. 4, heterocyclic compounds, and Vol. 5, biological compounds (e.g., proteins, carbohydrates, and lipids). Probably the most useful volume is Vol. 6, which contains formula, subject, and author indexes, as well as indexes of reactions and reagents. The last two of these not only refer to pages within the treatise, but directly give references to review articles and original papers Several similar treatises, including the nine-volume *Comprehensive Organometallic Chemistry* (1982), the eight-volume *Comprehensive Heterocyclic Chemistry* (1984), and the six-volume *Comprehensive Medicinal Chemistry* (1989) are also published by Pergamon. The indexes to these works also include references.
4. A major treatise devoted to experimental methods of chemistry is *Techniques of Chemistry*, edited first by A. Weissberger and then by J.K.M. Saunders, Wiley, New York. This publication, which began in 1970, so far consists of 21 volumes, most of them in several parts, covering such topics as electrochemical and spectral methods, kinetic methods, photochromism, and organic solvents. *Techniques of Chemistry* is a successor to an earlier series, called *Techniques of Organic Chemistry*, which appeared in 14 volumes, some of them in more than one edition, from 1945 to 1969.
5. *Comprehensive Chemical Kinetics,* edited by C.H. Bamford and C.F.H. Tipper, ***1969***, Elsevier, Amsterdam, is a multivolume treatise covering the area of reaction kinetics. Six of these volumes (not all published at the time of writing) deal with the kinetics and mechanisms of organic reactions in a thorough and comprehensive manner.
6. Three multivolume treatises that cover specific areas are R.C. Elderfield, *Heterocyclic Compounds,* Wiley, New York, ***1950***; R.H.F. Manske and H.L. Holmes, *The Alkaloids*, Academic Press, New York, ***1950***; and J.L. Simonson, L.N. Owen, D.H. R. Barton, and W.C.J. Ross, *The Terpenes*, Cambridge University Press, London, 1947–1957.
7. *Encyclopedia of Reagents for Organic Synthesis,* edited by L. Paquette, Wiley, New York, was published in 1995. It is an 8 volume, alphabetic listing of reagents used in organic chemistry with descriptions of the preparation, use and chemistry, with references. Each reagent was researched by organic chemists active in research, who contributed to the total publication.

This latter work is available online as **eEROS.** The *Encyclopedia of Reagents for Organic Synthesis*, e-EROS, provides updated information on ~3800 reagents with a database of close to 50,000 reactions. Each reagent entry includes properties (e.g., physical data, solubility, form supplied in, purification, and preparative methods); examples of use in reactions; and literature references. Search options include: name, CAS number, structure and reaction.

8. *Comprehensive Organic Synthesis*, edited by B.M. Trost and I. Fleming, Pergamon, was published in 1991. It is a 9 volume compilation.
9. *Comprehensive Organic Functional Group Transformations,* edited by A.R. Katritzky, O. Meth-Cohn, and C.W. Rees, Pergamon, was published in 1995. It is a 7 volume compilation.

C.iv. Monographs and Treatises on Specific Areas

There are many books devoted to organic chemistry that provide a thorough coverage of a specific area. Many of these are essentially very long review articles, differing from ordinary review articles only in size and scope. Some are comprised of a series of articles, edited by an organic chemist for a specific area of research. Some of the books are by a single author, and others have chapters by different authors. All, however, are carefully planned to cover a specific area. Many of these books have been referred to in footnotes in appropriate places in this book. There have been several series of monographs, one of which is worth special mention: *The Chemistry of Functional Groups,* under the general editorship of Z. Rappoport (S. Patai was the original editor), published by Wiley, New York. Each volume deals with the preparation, reactions, and physical and chemical properties of compounds containing a given functional group. There are >130 volumes in the series, covering functional groups have appeared so far, including books on alkenes, cyano compounds, amines, carboxylic acids and esters, quinones, and so far. Since 2003, the series has appeared both in print and online.

C.v. Textbooks

There are many excellent textbooks in the field of organic chemistry. We restrict ourselves to listing only a few of those published, mostly since 1985. Some of these are first-year texts and some are advanced (advanced texts generally give references; first-year texts do not, though they may give general bibliographies, suggestions for further reading, etc.); some cover the whole field, and others cover reactions, structure, and/or mechanism only. All the books listed here are not only good textbooks and the advanced books are valuable reference books for graduate students and practicing chemists.

Bruckner, *Advanced Organic Chemistry: Reaction Mechanisms*, Academic Press, ***2001***.

Bruice, *Organic Chemistry, 6th ed.*, Prentice-Hall, NJ, ***2010***.

Carey, *Organic Chemistry, 8th ed.*, McGraw-Hill, New York, ***2010***.

Carey and Sundberg, *Advanced Organic Chemistry: Structure and Mechanisms (Part A), 4th ed.*, Springer, ***2004***.

Carey and Sundberg, *Advanced Organic Chemistry: Structure and Mechanisms (Part B), 4th ed.*, Springer, ***2001***.

Carruthers and Coldham, *Some Modern Methods of Organic Synthesis, 4th ed.,* Cambridge University Press, Cambridge, ***2004***.

Ege, *Organic Chemistry: Structure and Reactivity, 5th ed.*, D.C. Houghton Mifflin, Boston ***2003***.

Fox and Whitesell, *Organic Chemistry, 3rd ed,* Jones and Bartlett, Sudbury, MA, ***2004***.

Grossman *The Art of Writing Reasonable Organic Reaction Mechanisms, 2nd ed*, Springer, ***2005***.

House, *Modern Synthetic Reactions, 2nd ed.,* W.A. Benjamin, New York, ***1972***.

Ingold, *Structure and Mechanism in Organic Chemistry, 2nd ed.*, Cornell University Press, Ithaca, NY, ***1969***.

Isaacs, *Physical Organic Chemistry,* Wiley, New York, ***1987***.

Jones, *Organic Chemistry, 4th ed.* W.W. Norton, New York, ***2009***.

Klein, *Organic Chemistry*, Wiley, New York, ***2011***.

Loudon, *Organic Chemistry, 5th ed.*, Oxford University Press, ***2009***.

Lowry and Richardson, *Mechanism and Theory in Organic Chemistry, 3rd ed.*, Harper and Row, New York, ***1987***.

McMurry, *Organic Chemistry, 8th ed.*, Brooks/Cole, Monterey CA, ***2012***.

Maskill, *The Physical Basis of Organic Chemistry,* Oxford University Press, Oxford, ***1985***.

Mundy, Ellerd and Favaloro, Jr. *Name Reactions and Reagents in Organic Synthesis, 2nd ed,* Wiley, ***2005***.

Ritchie, *Physical Organic Chemistry, 2nd ed.,* Marcel Dekker, New York, ***1989***.

Solomons and Fryhle, *Organic Chemistry, 10th ed.*, Wiley, New York, ***2011***.

Smith, *Organic Synthesis, 3rd ed.* Wavefunction Inc. and Elsevier, New York/London, ***2010***.

Smith, *Organic Chemistry: An Acid–Base Approach,* CRC Press, Boca Raton, FL, ***2011***.

Streitwieser, Heathcock and Kosower, *Introductory Organic Chemistry, 4th ed.,* Prentice Hall, ***1998***.

Sykes, A *Guidebook to Mechanism in Organic Chemistry, 6th ed.,* Longmans Scientific and Technical, Essex, ***1986***.

Vollhardt and Schore, *Organic Chemistry, 6th ed.,* W.H. Freeman, New York, ***2010***.

Wade, *Organic Chemistry, 7th ed.,* Prentice-Hall, Upper Saddle River, NJ, ***2009***.

C.vi. Other Books

In this section, we mention several books that do not fit conveniently into the previous categories. All but the last have to do with laboratory synthesis.

1. *Organic Syntheses*, published by Wiley, New York is a collection of procedures for the preparation of specific compounds. *Organic Syntheses* is currently available online.[34] The thin annual volumes have appeared each year since 1921. For the first

[34] Available at http://www.orgsyn.org/

59 volumes, the procedures for each 10- (or 9-) year period are collected in cumulative volumes. Beginning with Vol. 60, the cumulative volumes cover 5-year periods. The cumulative volumes published so far are

Annual Volumes	Collective Volumes
1–9	**I**
10–19	**II**
20–29	**III**
30–39	**IV**
40–49	**V**
50–59	**VI**
60–64	**VII**
65–69	**VIII**
70–74	**IX**
75–80	**X**
81–84	**XI**

The advantage of the procedures in *Organic Syntheses*, compared with those found in original journals, is that these procedures are *tested*. Each preparation is carried out first by its author and then by a member of the *Organic Syntheses* editorial board, and only if the yield is essentially duplicated is the procedure published. While it is possible to repeat most procedures given in journals, this is not always the case. All *Organic Syntheses* preparations are noted in Beilstein and in *CA*. In order to locate a given reaction in *Organic Syntheses*, the reader may use the OS references given in the present volume (through OS **69**); the indexes in *Organic Syntheses* itself; R. Shriner and R. Shriner, "*Organic Syntheses* Collective Volumes **I**, **II**, **III**, **IV**, **V** Cumulative Indices", Wiley, New York, ***1976***, or S. Sugasawa and S. Nakai; "Reaction Index of *Organic Syntheses*", Wiley, New York, ***1967*** (through OS **45**). Another book classifies virtually all the reactions in *Organic Syntheses* (collective vols. **I–VII** and annual vols. 65–68) into 11 categories: annulation, rearrangement, oxidation, reduction, addition, elimination, substitution, C—C bond formation, cleavage, protection/deprotection, and miscellaneous. This is *Organic Syntheses: Reaction Guide*, by D. Liotta and M. Volmer, published by Wiley, New York, in ***1991***. Some of the categories are subdivided further, and some reactions are listed in more than one category. What is given under each entry are the equation, the volume, and page reference to *Organic Syntheses*.

2. Volume 1 of *Reagents for Organic Synthesis*, by L. Fieser and M. Fieser, Wiley, New York, ***1967***, is a 1457–page volume that discusses, in separate sections, some 1120 reagents and catalysts. It tells how each reagent is used in organic synthesis (with references) and, for each, tells which companies sell it, or how to prepare it, or both. The listing is alphabetical. There are now a total of 25 volumes published as of 2009, which continue the format of Vol. 1 and add more recent material. A cumulative index for Vols. 1–12, by J. Smith and M. Fieser, was published in ***1990***. A cumulative index for volumes 1–22 was published in ***2005***, by M.B. Smith. The series included volumes 1–18 with Mary Fieser.

   After the death of Mary Fieser, the series was resumed by T.-L. Ho and now includes volumes 19–25.

3. *Comprehensive Organic Transformations, 2nd ed.* by R.C. Larock, Wiley–VCH, New York, ***1999***, has been frequently referred to in footnotes in Part 2 of this book. This compendium is devoted to listings of methods for the conversion of one functional group into another, and covers the literature through 1987. It is divided into nine sections covering the preparation of alkanes and arenes, alkenes, alkynes, halides, amines, ethers, alcohols and phenols, aldehydes and ketones, and nitriles, carboxylic acids and derivatives. Within each section are given many methods for synthesizing the given type of compound, arranged in a logical system. A schematic equation is given for each method, and then a list of references (without author names, to save space) for locating examples of the use of that method. When different reagents are used for the same functional group transformation, the particular reagent is shown for each reference. There is a 164 page index of group transformations. The 2nd edition has only recently been published and is *not* referenced in this edition, and a CD–ROM version is now available.
4. *Survey of Organic Synthesis*, by C.A. Buehler and D.E. Pearson, Wiley, New York, 2 vols., ***1970***, ***1977***, discusses hundreds of reactions used to prepare the principal types of organic compounds. The arrangement is by chapters, each covering a functional group (ketones, acyl halides, amines, etc.). Each reaction is thoroughly discussed and brief synthetic procedures are given. There are many references.
5. A similar publication is S. Sandler and W. Karo, *Organic Functional Group Preparations, 2nd ed.,* 3 vols., Academic Press, New York, 1983–1989. This publication covers more functional groups than Buehler and Pearson.
6. *Compendium of Organic Synthetic Methods,* Wiley, New York, contains equations describing the preparation of thousands of monofunctional and difunctional compounds with references. Twelve volumes have been published so far (Vols. 1–2, edited by I.T. Harrison and S. Harrison; Vol. 3, edited by L. Hegedus and L.G. Wade, Jr.; Vol. 4–5, edited by L.G. Wade, Jr.; Vols. 6–12, edited by M.B. Smith). Volume 13 will appear in 2014.
7. *The Vocabulary of Organic Chemistry,* by M. Orchin, F. Kaplan, R.S. Macomber, R. M. Wilson, and H. Zimmer, Wiley, New York, ***1980***, presents definitions of >1000 terms used in many branches of organic chemistry, including stereochemistry, thermodynamics, wave mechanics, natural products, and fossil fuels. There are also lists of classes of organic compounds, types of mechanism, and name reactions (with mechanisms). The arrangement is topical rather than alphabetical, but there is a good index. *Compendium of Chemical Terminology,* by V. Gold, K.L. Loening, A. D. McNaught, and P. Sehmi (the "Gold book"), published by Blackwell Scientific Publications, Oxford, in ***1987***, is an official IUPAC list of definitions of terms in several areas of chemistry, including organic.

D. LITERATURE SEARCHING

Until recently, searching the chemical literature meant looking only at printed materials (some of which might be on microfilm or microfiche). Now, however, virtually all of the literature can be searched online. Whether the search is online or uses only the printed material, there are two basic types of search, (1) searches for information about one or more specific compounds or classes of compounds, and (2)

other types of searches. First, we will discuss searches using only printed materials, and then online searching.[35]

D.i. Literature Searching Using Printed Materials

Searching for Specific Compounds. Organic chemists often need to know if a compound has ever been prepared and if so, how, and/or they may be seeking a melting point, an ir spectrum, or some other property. Someone who wants all the information that has ever been published on any compound begins by consulting the formula indexes in Beilstein (sec. Appendix A.B.iii). At this time there are two ways to do this. (1) The formula index to the second supplement (Vol. 29, see Appendix A.B.iii) will quickly show whether the compound is mentioned in the literature through 1929. If it is there, the searcher turns to the pages indicated, where all methods used to prepare the compound are given, as well as all physical properties, with references. Use of the page heading method described in Appendix A.B.iii will then show the locations, if any, in the third and later supplements. (2) If one has an idea what volume of Beilstein the compound is in (and the tables of contents at the front of the volumes may help), one may search the cumulative index for that volume. If not sure, one may consult several indexes. One of these two procedures will locate all compounds mentioned in the literature through 1959. If the compound is heterocyclic, it may be in the fifth supplement. If it is in Vols. 17–19 (or in a later volume whose index has been published), the corresponding indexes may be consulted. If not, the page heading method will find it, if it was reported before 1960.[36] There is a way by which all of the above can be avoided. At this point, the investigator will know (1) all information published through 1959 or 1979,[35] or (2) that the compound is not mentioned in the literature through 1959 or 1979.[37] In some cases, scrutiny of Beilstein will be sufficient, perhaps if only a boiling point or a refractive index is required. In other cases, especially where specific laboratory directions are needed, the investigator will have to turn to the original papers.

To carry the search to more recent articles, the chemist turned to the collective formula indexes of *Chemical Abstracts* and such later collective indexes as have appeared; and the semiannual indexes thereafter. *However, such searches now would use SciFinder*.

If the compound has not been reported, the investigator will know that. Indeed, this is perhaps the most important consideration when considering a new area of research. It should be pointed out that for common compounds (benzene, ether, acetone, etc.), trivial mentions in the literature are not indexed (so they will not be found by this procedure), only significant ones. Thus, if acetone is converted to another compound, an index entry will be found, but not if it is used as a solvent or an eluant in a common procedure.

[35] For a monograph that covers both online searching and searching using printed materials, see Wiggins, G. *Chemical Information Sources*, McGraw-Hill, NY, ***1991***.

[36] Compounds newly reported in the fifth supplement that are in a volume whose index has not yet been published will not be found by this procedure. To find them in Beilstein, it is necessary to know something about the system, but they may also be found by consulting *SciFinder*.

[37] For those heterocyclic compounds that would naturally belong to a volume for which the fifth supplement has been published.

While online searching is extraordinarily powerful, it should be pointed out that there are two problems with computer searches. First of all, far too many "hits" may be returned. For example, a 2011 research topic search (see Appendix A.D.iii) of the topic "macrolactones from hydroxy acids" gave the results:

Research Topic Candidates	References
159 references were found containing the two concepts "macrolactones" and "hydroxy acids" closely associated with one another	159
474 references were found where the two concepts "macrolactones" and "hydroxy acids" were present anywhere in the reference	474
35157 references were found containing the concept "macrolactones"	35157
193323 references were found containing the concept "hydroxy acids"	193323

Clearly, only examining the first few hundred references is practical. The search can, and must be refined. Depending on the scope of the search, this fact can be a limitation. The second problem relates to the search words used (the keywords). If they are too broad, little useful information is returned. If the keywords are too narrow in scope, many useful references may be missed. The point of these two cautions is to take care in choosing keywords. On the other hand, using many related keywords and doing multiple searches is very easy using SciFinder, and is probably a good strategy.

Often, all the information one needs about a compound will be found in one of the handbooks (Appendix A.C.i), in the *Dictionary of Organic Compounds* (Appendix A.C.i), or in one of the other compendia listed in this chapter, most of which give references to the original literature.

Other Searches. There is no definite procedure for making other literature searches using only printed materials. Any chemist who wishes to learn all that is known about the mechanism of the reaction between aldehydes and HCN, or which compounds of the general formula Ar_3CR have been prepared, or which are the best catalysts for *Friedel–Crafts acylation* of naphthalene derivatives with anhydrides, or where the group —$C(NH_2)$=N— absorbs in the IR, is dependent on ingenuity and knowledge of the literature. If a specific piece of information is needed, it may be possible to find it in one of the compendia mentioned previously. If the topic is more general, the best procedure is often to begin by consulting one or more monographs, treatises, or textbooks that will give general background information and often provide references to review articles and original papers. In many cases this is sufficient, but when a complete search is required, it is necessary to consult the *CA* subject and/or chemical substance indexes, and also *SciFinder*, where the ingenuity of the investigator is most required, for now it must be decided which words to look under. This statement relates to the keyword used for a computer search, as indicated above. If one is interested in the mechanism of the reaction between aldehydes and HCN, one might look under "aldehydes", or "hydrogen cyanide", or even under "acetaldehyde" or "benzaldehyde", and so on, but then the search is likely to prove long. A better choice in this case would be "cyanohydrin", since these are the normal products and references there would be fewer. It would be a waste of time to look under "mechanism". In any case, many of the abstracts would not prove helpful. If it is necessary to search before 1907

(and even before 1920, since *CA* was not very complete from 1907 to ~1920), recourse may be made to *Chemisches Zentralblatt* and the abstracts in the *Journal of the Chemical Society*.

D.ii. Literature Searching Online[20]

Most of the *Chemical Abstracts* literature can be accessed online via *CAS*, using *SciFinder* in Appendix A.D.iii, the largest and most current database of chemical substance information in the world. *CAS* is located in Columbus, Ohio and is a division of the American Chemical Society. *CAS* can be contacted at Chemical Abstracts Service, 2540 Olentangy River Road, P.O. Box 3012, Columbus, Ohio 43210 (e-mail: help@cas.org). *CAS* is a team of scientists who provide digital information environment for scientific research and discovery. *CAS* provides pathways to published research in the world's journal and patent literature back to the beginning of the 20th century. Since 1907, *CAS* has indexed and summarized chemistry-related articles from >40,000 scientific journals, in addition to patents, conference proceedings and other documents pertinent to chemistry, life sciences, and many other fields. Through the printed *CA* (*Chemical Abstracts*), *CA* on CD, STN, the *CAS* files distributed through licensed vendors, the *SciFinder* and *SciFinder Scholar* desktop research tools, and the *STN Easy* or *STN* on the Web services, data produced by *CAS* is accessible to virtually any scientific researcher worldwide in industry, governmental research institutions, and academia.

Substance identification is a special strength of *CAS*. It is widely known as the *CAS Registry*, the largest substance identification system in existence. When a chemical substance, newly encountered in the literature, is processed by *CAS*, its molecular structure diagram, systematic chemical name, molecular formula, and other identifying information are added to the Registry and it is assigned a unique *CAS Registry* Number.

The *CAS REGISTRY* mostly covers substances identified from the scientific literature from 1957 to the present with some classes (fluorine- and silicon-containing compounds) going back to the early 1900s. An important piece of information that assists in such a search is the *CAS* registry number. Each substance in *REGISTRY* is identified by a unique numeric identifier called a CAS Registry Number.[38] "The CAS Registry number is a unique number assigned to a chemical by the Chemical Abstracts Service.[39] A fairly large collection of *CAS* numbers, with links to safety data for many chemicals, can be found at the listing of chemicals by *CAS* number at the Safety Home Page of the Physical and Theoretical Chemistry Laboratory at Oxford University".[40] The CAS Registry Number is a unique numeric identifier that designates only one substance, has no chemical significance, and is a link to finding information about a specific chemical substance. A *CAS* Registry Number includes up to 9 digits that are separated into 3 groups by hyphens. The first part of the number, starting from the left, has up to 6 digits; the second part has 2 digits. The final part consists of a single check digit.[41]

Online searching means using a computer terminal to search a *database*. Although databases in chemistry are available from several organizations, STN International (The

[38] Available at http://www.cas.org/EO/regsys.html
[39] Available at http://www.cas.org/
[40] Available at http://ptcl.chem.ox.ac.uk/MSDS/glossary/casnumber.html
[41] Available at http://www.cas.org/EO/checkdig.html

Scientific & Technical Information Network) is important because it is comprehensive and available in many countries. STN has dozens of databases, including many that cover chemistry and chemical engineering. To access these databases a chemistry department, a library, or an individual subscribes to STN (for a nominal fee), and receives code numbers that will permit access to the system, usually via a desktop computer.

D.iii. SciFinder—the CAS database[42]

Tutorials are available to help use Sci-Finder.[43] SciFinder can search a research topic[44] or a compound can be searched by structure[45] The search engine is known as STN Express with Discover![46] and can easily and efficiently search >200 scientific and technical databases online through STN®.[47] The Analysis Edition of STN Express with Discover! allows one to search, analyze, visualize, and discover sci-tech information by the ability to create a table for substance analysis that identifies the common substructure for an answer set of structurally related substances: Group related author/inventor names and company names for better analysis and visualization results; Analyze and tabulate data from single- or multi-file search results, and create a data table and 3D chart; Save an answer set from databases (e.g., CAplusSM, PCTFULL, and USPATFULL) with the Save for STN AnaVist Wizard, and then import and open it in STN® AnaVistTM; Create an interactive spreadsheet from all or only hit CAS Registry Numbers and their corresponding CAS Roles through the CAS Registry Number®; Upload lengthy genetic sequences automatically for searching in DGENE and PCTGEN via the Upload Query Wizard. STN Express was developed in collaboration with Hampden Data Services.

To illustrate how STN is used, an online tutorial is available.[48] A few online windows from a *SciFinder* search are provided to illustrate how searches can be done. This presentation is by no means complete or intended as an alternative to the actual tutorial. Indeed, one could *not* use *SciFinder* properly after simply reading this discussion. The intent is to illustrate some features that are available and to present an overview of the use of this important tool.

Using *SciFinder*®, a search can be done in one of several different ways. Searches can be done by research topic, by substances, or by reactions. The latter two searches use drawing tools that are part of *SciFinder*. An example is shown of a search done by research topic:[49] The example shown in Fig. A.3. shows a search for intramolecular hydroamination of aminoalkenes. To begin, click Explore by research topic and enter the appropriate information.

It is possible to use filters (see Fig. A.1) in order to refine the search by year, document type (journal, patent, review, etc.), author or company. A window is returned that contain references categorized by their relationship to the search phrase, as shown in Fig. A.2. One simply checks those reference lists that appear closest to those of interest.

FIG. A.1. Explore by research topic.

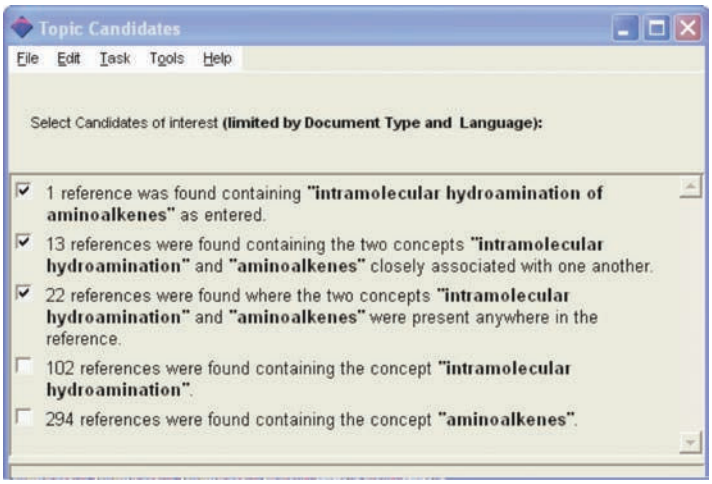

FIG. A.2. Selection of candidates of interest for search by research topic.

After clicking on "get references," a screen is returned (Fig. A.3) that has the original references, as shown in the window. One is given the option of refining this list further, and for each reference, most browsers allow viewing the abstract or the full references as an HTML or a PDF file. However, your library must have paid the appropriate fees so the journal and volumes of interest are available online. Otherwise, interlibrary loan or direct ordering of the article may be necessary.

Other examples of typical searches allowed by SciFinder include search by author's name,[50] as with the example of Professor K. Barry Sharpless shown in Fig. A.4. Search by structure is also possible,[51] such as the example shown in Fig. A.5, using SciFinder drawing tools. Once a structure is drawn, SciFinder searches to find matches based on that structure. The drawing tools can be used to show a reaction, and reaction information is returned, as shown in Fig. A.6. Ultimately, journal article and/or patents are returned that provide direct access to the literature of interest.

FIG. A.4. Screen shot for beginning a search by author.

D.iv. Science Citation Index

As seen in the SciFinder search tutorials, it is possible to track papers that have cited a particular article or author. A publication that can greatly facilitate literature searching is *Science Citation Index(*SCI*)*, begun in 1961. This publication, which is quite different from any other mentioned in this chapter, gives a list of all papers in a given year that have cited a

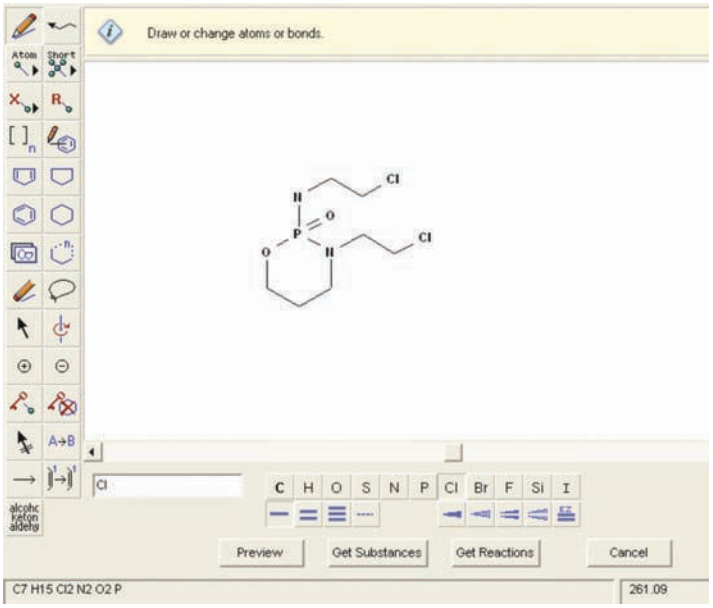

FIG. A.5. Screen shot for beginning a search by structure, using the drawing tools.

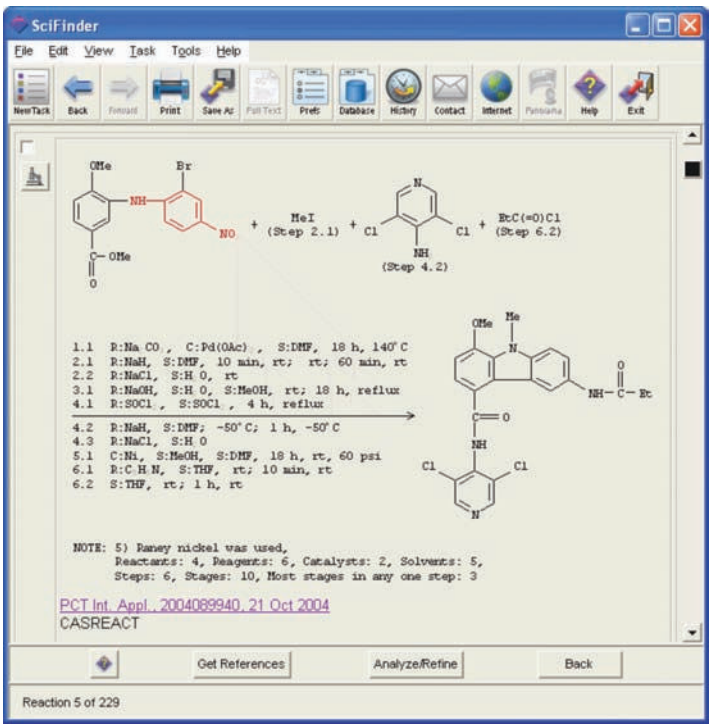

FIG. A.6. Screen shot of results for a search by reaction, using the drawing tools.

given paper, patent, or book. Its utility lies in the fact that it enables the user to search *forward* from a given paper or patent, rather than backward, as is usually the case. For example, suppose a chemist is familiar with a paper by W.P. Jencks and M. Gilchrist (*J. Am. Chem. Soc.,* ***1968***, *90*, 2622) entitled "Nonlinear Structure–Reactivity Correlations. The Reactivity of Nucleophilic Reagents toward Esters". The chemist is easily able to begin a search for earlier papers by using references supplied in this paper and can then go further backward with the aid of references in those papers, and so on. But for obvious reasons the paper itself supplies no way to locate *later* papers. *Science Citation Index* is designed to make up for this gap. The citation index of *SCI* lists all papers, patents, or books cited in a given year or 2-month period (by first author only) and then gives a list of papers that have done the citing. The index is published bimonthly and cumulated annually. For example, column 43901 of the 1989 citation index shows that the Jencks paper mentioned above was cited as a footnote in 16 papers published in 1989. It is reasonable to assume that most of the papers that cited the Jencks paper were on closely related subjects. For each of the 16 papers are listed the first author, journal abbreviation, volume and page numbers, and year. In a similar manner, if one consulted *SCI* for all the years from 1968 to date, one would have a complete list of papers that cited that paper. One could obviously broaden the search by then consulting *SCI* (from 1989 on) for papers that cited these 16 papers, and so on. Papers, patents, or books listed (e.g., in the 1989 *SCI*) may go back many years (e.g., papers published by A. Einstein in 1905 and 1906 are included). The only requirement is that a paper published in 1989 (or late 1988) has mentioned the earlier paper in a footnote. The arrangement of cited papers or books is alphabetical by cited first author and then by cited year. Cited patents are listed in a separate table, in order of patent number, though the inventor and country are also given.

SCI covers ~3200 journals in the physical and biological sciences, as well as in medicine, agriculture, and technology. In addition to the citation index, each bimonthly and annual *SCI* also includes three other indexes. One of these, called *Source Index*, is similar to the *CA* author index. It lists the titles, journal abbreviations, volume, issue, page numbers, and year of all papers published by a given author during that 2-month period or year. All authors are listed; not just first authors. The second, called the *Corporate Index*, lists all publications that have been published from a given institution during that period, by first author. Thus, the corporate index for 1989 lists 63 papers by 45 different first authors emanating from the Department of Chemistry of Rutgers University, New Brunswick, NJ. The main section of the corporate index (the Geographic Section) lists institutions by country or (for the US) by state. There is also an Organization Section, which lists the names of institutions alphabetically, and for each gives the location, so it can be found in the geographic section. The third index included in *SCI* is the *Permuterm*[52] *Subject Index*. This index alphabetically lists every significant word in the titles of all papers published in that year or bimonthly period, paired with all other significant words in the same title. Thus, for example, a title with seven significant words appears at 42 separate places in the index. Each of the seven words appears six times as the main word, each time paired with a different word as the coword. The user is then led to the *Source Index*, where the full reference is given. *Science Citation Index* is also available online (though not through STN) and on CD–ROM discs. A version of *SCI* that is restricted to chemistry but also includes searchable abstracts, is available only in the CD–ROM format.

[52] Registered trade name.

The publishers of *SCI* also produce another publication, called *Index to Scientific Reviews* that appears semiannually. This publication, which began in 1974, is very similar to *SCI*, but confines itself to listing citations to review articles. The citations come from ~2500 journals in the same general areas as are covered by *SCI*. The review articles cited appeared in ~215 review journals and books, as well as in those journals that publish occasional review articles. Like *SCI*, the *Index to Scientific Reviews* contains citation, source, corporate, and Permuterm indexes. It also contains a "Research Front Specialty Index", which classifies reviews by subject.

D.v. How to Locate Journal Articles

Having obtained a reference from various sources or searches, one often needs to consult the original journal (patents are discussed in Appendix A.A.ii). The first step is to ascertain the full name of the journal, since it is the abbreviation that is generally given. Of course, everyone should be familiar with the abbreviations of the very important journals (*J. Org. Chem.*, *Chem. Ber.*, etc.), but references are often found to journals whose titles are not at all familiar (e.g., *K. Skogs Lantbruksakad. Tidskr.* or *Nauchn. Tr. Mosk. Lesotekh. Inst.*). In such cases, one consults the *Chemical Abstracts Service Source Index(*CASSI*)*, 1989 edition, which contains the names of all the journals covered by *CA* from 1907 to 1989 (even those no longer published), with the most recent abbreviations in bold print. *Chemical Abstracts Service Source Index* also lists journals covered by *Chemisches Zentralblatt* and its predecessors from 1830 to 1969, and journals cited in Beilstein before 1907. The journals are listed in alphabetical order of the *abbreviations*, not of the titles. Journal title changes have not been infrequent, and *CASSI* also contains all former names, with cross-references to the current names. Quarterly supplements, cumulated annually, to *CASSI* have appeared since 1990 listing new journals and recent changes in journal titles. Note that while many publications use the *CA* abbreviations, not all do. Usage will vary from country to country, and even from journal to journal within a country. Furthermore, the *CA* abbreviations have changed from time to time. This latter point is particularly important when doing keywords searches. Using a structure search in SciFinder may get around this problem.

Once the complete title is known, the journal can easily be obtained if it is in the library customarily used by the chemist, or if that journal is available in electronic form. If not, one must use another library. The next step is to find out which libraries carry the journal and *CASSI* answers this question too, since it carries a list of some 360 libraries in the United States and other countries. *For each journal it tells which of these libraries carries it*, and furthermore, if the holdings are incomplete, which volumes of that journal are carried by each library. However, most libraries have an inter-library loan service that will provide access to such journal articles. It may be possible to visit the closest library personally and *CASSI* also includes lists of journal publishers, sales agents, and document depositories. Photocopies of most documents cited in *CA* can be obtained from chemical Abstracts Document Delivery Service, Customer Services, 2540 Olentangy River Road, Columbus OH, 43210, USA. Orders for documents can be placed by mail, telephone, Telex, fax, or online through STN or other services.

These latter comments are largely out of date given the online status of most journals. As mentioned above, PDF files of an article can be downloaded, or they can be read directly via the HTML file using any current browser. The reader is encouraged to contact the library person in your establishment that is responsible for chemical literature and to learn which online services are available through your local library.

D.vi. REAXYS® [53]

Launched in 2009, "Reaxys was created through the merger of the existing *CrossFire* databases (AppendixA.B.iii.) into a single database with a new and intuitive user interface. Reaxys is a fully integrated content source providing in-depth coverage of inorganic, organic, and organometallic small molecule chemistries excerpted from appropriate journal and patent literature".[54] Reaxys is available online with drawing tools that allows entry of a structure, or multiple structures as part of a reaction. Once the structure is drawn, Reaxys offers several options for the search:

Reaxys is a unique workflow solution for research chemists providing in depth coverage of inorganic, organic, and organometallic small molecule chemistries. The database consists of chemical compounds and related factual properties; chemical reaction and synthesis information; related bibliographic data, all of which have been excerpted from a carefully selected list of journals and patents: The latter is sourced from carefully selected patent classes and patent offices. This content is delivered through a web-based interface, designed for chemists, with powerful functionality that delivers the content in a flexible and intuitive way and helps a chemist with his/her major information tasks.

At the heart of Reaxys is the concept of "Chemistry as the organizing principle". This means that the chemical compound or reaction is central to the way in which the data is organized in the database. This is fundamentally different from bibliographic databases in which a journal or patent record is at the center. This chemically focused approach allows all data from multiple sources to be combined together in one de duplicated record for a given compound or reaction (i.e., a single compound or reaction can have multiple source citations, whereas a bibliographic database will have one record per published item, so the same compound or reaction may be found in multiple records).

The value of Reaxys to organic chemists may be understood best in relation to the synthesis of compounds, which is at the core of organic chemistry. Devising new routes to unique and artificial scaffolds requires the skills of planning and executing multistep syntheses and having a toolbox of methodologies at one's disposal. However, even the best conceived synthesis plans may require modifications, fine-tuning or entire rerouting, and chemists are faced with the daily challenge of choosing the right combination of reagents and building blocks for a whole set of problems: Which building blocks are optimal? In which sequence should they be assembled? Which reactions accomplish the task best? The Reaxys synthesis planning tool has been designed to make these choices as painless as possible using information and data from the journal and patent literature to investigate a number of possible alternative synthetic routes.

As an example, searching for papers that have reported direct arylation of indoles at the C-3 position. Construct a graphical search query (using one of the common graphical chemical structure editors, e.g., ChemDraw), with GH on indole nitrogen and also at the 5- and 6-positions of indole. The screen in Fig. A.7. shows the entry information required for the search. This query, retrieved 164 reactions from 45 citations (search results obtained in February 2012):

[53] Available at https://www.reaxys.com/info/
[54] Available at Reaxys_whitepaper_2011_whatsinReaxys.pdf

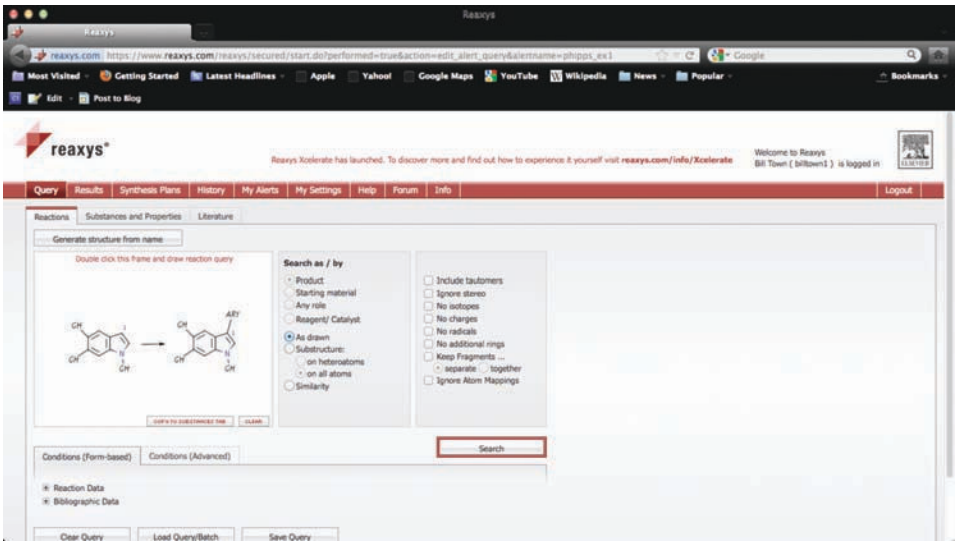

FIG. A.7. Search for direct arylation of indoles at C-3.

The Reaxys Version used in the above example is Application version: 1.0.9619; Content last updated: February 2012; Reactions: 31.681.788; Substances: 20.286.045; Citations: 4.504.504. Figure A.8 shows details for one of the reactions returned for this search. Also shown on this screen are various parameters that are available to search for this example. The original publication from which the reaction was taken is readily available.

It is also possible to expand the literature review by viewing the details of any recent articles that cite articles of interest. This is easily achieved by clicking on the 'view citing

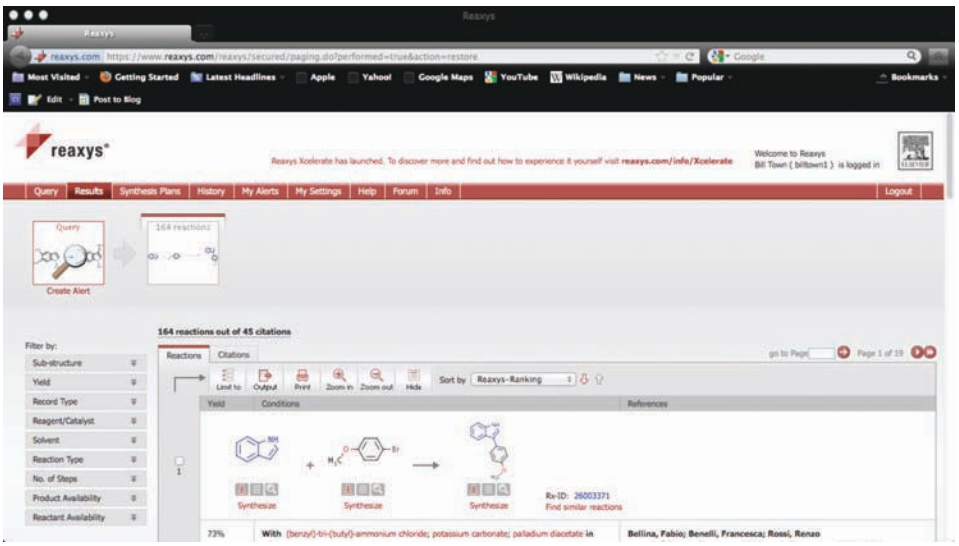

FIG. A.8. One reaction returned for this search.

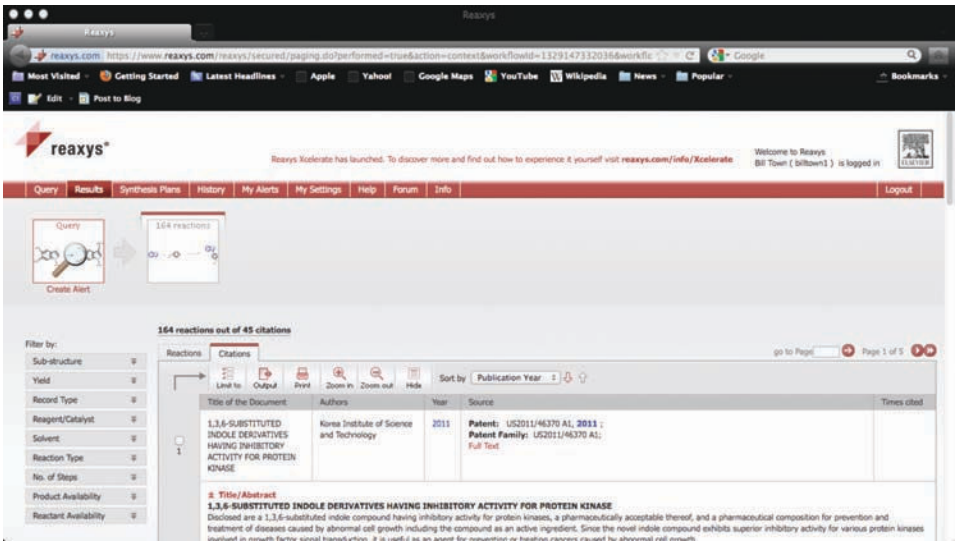

FIG. A.9. Papers that cited the work in Fig. A.8.

articles' hyperlink. The reaction shown in Fig. A.8 was cited in the patent literature and also in the *Journal of Organic Chemistry*, as shown in Fig. A.9. In this manner, relevant, more recent articles may be identified and explored using citation data from Scopus. A few of such citations are shown in Fig. A.10.

The synthesis planning tool allows a more in depth investigation. The Reaxys synthesis tool makes it easy to add more steps to the synthesis plan by searching the journal and patent literature for reactions designed to prepare the precursor molecules in any reaction step. Figure A.11 illustrates how a synthesis of a target that is consistent with the original

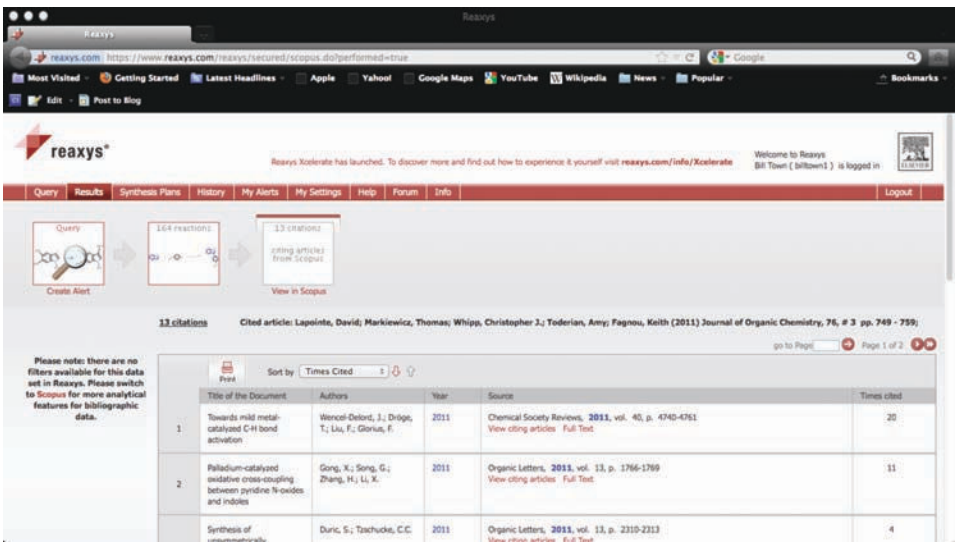

FIG. A.10. Other potentially relevant papers based on an expanded search.

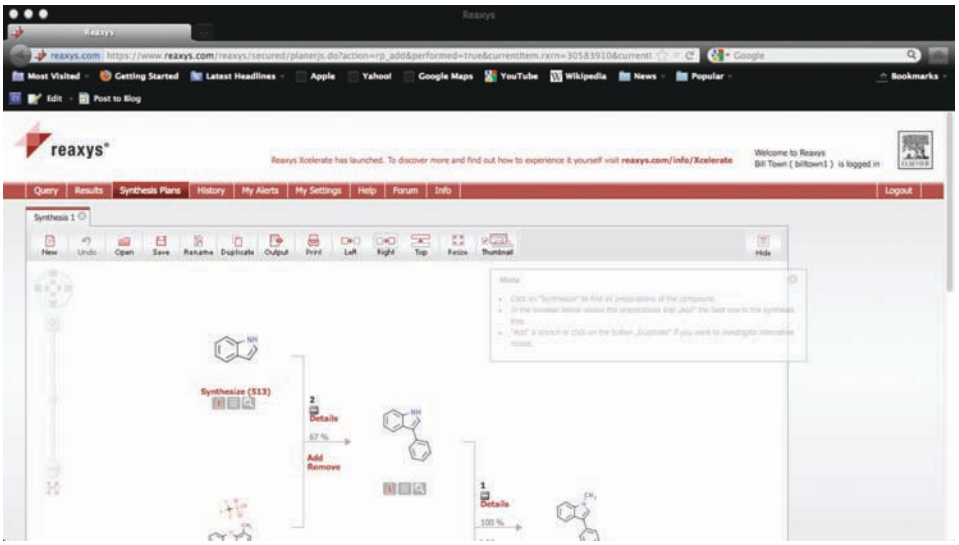

FIG. A.11. Synthesis plan for 3-phenylindole.

search parameters may be constructed. Extensive property data for chemical substances is available at every stage in the process. Reaxys is a valuable addition to the information resources used by synthetic chemists.

APPENDIX B

Classification of Reactions by Type of Compounds Synthesized

ACETALS

acetals + RM **10-64**
aldehydes + alcohols **16-05**
by transetherification **10-13**
from dihalides **10-08**
from hydroxy-ethers **14-06**
ortho esters + RM **10-64**
reductive cleavage of ortho esters **19-56**

ACYLALS (DIESTERS)

aldehydes + anhydrides **16-06**

ACYLOINS: See hydroxy-ketones

ALCOHOLS

addition of other organometallics to carbonyls **16-25**
aldehydes + allylic silanes **16-51**
alkenes + alcohols **15-33**
alkenes + aldehydes or ketones **16-54**
alkenes-oxymercuration **15-03**
amides + organometallic compounds **16-82**
amines + KOH **10-23**
anhydrides + organometallic compounds **16-82**
aromatics + carbonyls **11-12**
arylation of ketones **11-12**
boranes + CO; oxidation **18-23**
boranes + CO; reduction **18-24**
by the Cannizzaro reaction **19-81**
by Wittig rearrangement **18-22**
carboxylic esters + organometallics **16-82**
cleavage of ethers **10-49**
condensation of aldehydes **19-81**
conjugate reduction **15-14**
epoxides + organometallics **10-65**
epoxides + silanes **10-55**
from alcohols **10-17**
from amines **10-23**
from boranes **10-01**
from boranes **12-27**
from boranes **18-23**
from boronates **18-23**
from epoxides **10-65**
from ethers **10-13**
from silanes **10-16**
Grignard addition to aldehydes or ketones **16-24**
hydration of alkenes **15-03**
hydrolysis of acetals and ketals **10-06**
hydrolysis of alkyl halides **10-01**
hydrolysis of inorganic esters **10-04**
hydrolysis of sulfonate esters **10-04**
hydrolysis of vinyl ethers **10-06**
hydroxylation at aliphatic carbon **19-14**
hydroxymethylation of arenes **11-12**
organolithium addition to aldehydes or ketones **16-24**
organometallics + oxygen **12-25**
oxidation of boranes **12-27**
oxidation of boranes **15-16**
oxidation of boranes **18-23**

March's Advanced Organic Chemistry: Reactions, Mechanisms, and Structure, Seventh Edition. Michael B. Smith.

oxidation of methylene **19-15**
oxidation of silanes **10-16**
radical addition to carbonyl compounds **16-56**
rearrangement of ethers **18-22**
rearrangement of peroxides **18-20**
reduction of acyl halides **19-63**
reduction of aldehydes or ketones **19-36**
reduction of carbonyls with Grignard reagents **16-24**
reduction of carboxylic acids **19-37**
reduction of carboxylic esters **19-38**
reduction of carboxylic esters **19-65**
reduction of conjugated ketones **15-44**
reduction of epoxides **19-35**
reduction peroxides **19-60**
ring expansion of amines **18-03**
silanes + aldehydes or ketones **16-26**

ALCOHOLS, ALLYLIC
addition of allylic organometallics to carbonyls **16-25**
alkenes + formaldehyde **16-54**
allylic silanes + aldehydes or ketones **16-26**
deprotonation of epoxides **17-03**
rearrangement of alkene-sulfoxides **18-35**

ALDEHYDES
alkenes + aldehydes **15-33**
alkyl halides + organoiron compounds **10-76**
alkylation of aldehydes **10-68**
alkylation of imines **10-68**
alkylation reactions **10-67**
and keto–enol tautomerism **12-03**
aromatic compounds: Friedel–Crafts **11-18**
arylation of aldehydes **13-14**
boranes + $MeO(ArS)CH_2Li$ **18-24**
by decarboxylation **12-40**
by rearrangement of aldehydes **18-04**
by the Wacker process **19-25**
carbonylation of alkenes **15-37**
carbonylation of aromatic compounds **11-18**
carbonylation of hydrocarbons **12-33**
formylation of aromatic compounds **11-18**
from alkyl halides **10-64**
from alkyl halides **10-76**
from aryl imines **11-18**
from dihydrooxazines **10-72**
from dithianes **10-71**
from dithioaldehydes **16-11**
from organometallics **12-33**
from oxazines **10-72**
hydration of alkynes **15-04**
hydroformylation **15-37**
hydrolysis of acetals **10-05**
hydrolysis of C=N compounds **16-02**
hydrolysis of *gem*-dihalides **10-02**
hydrolysis of nitro compounds **16-03**
hydrolysis of vinyl ethers **10-06**
hydrolysis of vinyl halides **10-04**
Michael addition **15-24**
oxidation of alcohols **19-03**
oxidation of aryl methyl groups **19-18**
oxidation of nitro compounds **19-21**
oxidation of primary alkyl halides **19-20**
oxidative cleavage of diols **19-07**
oxidative cleavage of epoxides **19-07**
ozonolysis of alkenes **19-09**
reduction anhydrides **19-40**
reduction nitriles **19-44**
reduction of acid anhydrides **19-40**
reduction of acyl halides **19-39**
reduction of amides **19-41**
reduction of carboxylic acids **19-40**
reduction of carboxylic esters **19-40**

ALDEHYDES, CONJUGATED
by aldol condensation **16-34**

ALKANES
alcohols + RM **10-63**
alkane addition to alkenes **15-18**
alkenes + alkyl radicals **15-29**
alkenes + diimide **15-12**
alkenes + metals **15-12**
alkenes + organometallics **15-21**
alkyl halides + metals **10-56**
alkyl halides + metals **10-57**
alkyl halides + organocuprates **10-58**
alkyl halides + RM (Li, Na, K) **10-57**
alkyl halides + RM (other metals) **10-59**

alkyl halides + silanes **10-55**
Barton–McCombie reaction **19-58**
by [2 + 2]-cycloaddition **15-63**
by [3 + 2]-cycloaddition **15-59**
by decarboxylation **12-40**
cleavage of alkanes **12-47**
cleavage of ketones **12-46**
coupling of boranes **14-26**
coupling of carboxylate salts **14-29**
coupling of Grignard reagents **14-24**
coupling of organocuprates **14-25**
coupling of two alkanes **14-15**
decarbonylation of aldehydes **14-32**
decyanation **12-48**
from alcohols **10-63**

from organometallics **12-23**
from organometallics **12-24**
from S compounds **10-61**
from S compounds **14-27**
from silanes **10-55**
Grignard reagents with metal compounds **14-24**
homocoupling of organocuprates **14-24**
hydrogen exchange **12-01**
hydrogenation of alkenes **15-11**
hydrogenation of alkynes **15-11**
hydrogenation of aromatic compounds **15-13**
inorganic esters + RM **10-61**
insertion by carbenes **12-21**
Kolbe reaction **14-29**
pyrolysis of peroxides **17-37**
radical addition to alkenes **15-29**
radical coupling of alkanes **14-14**
radical cyclization of alkenes **15-30**
reduction dithianes **10-71**
reduction of acyl halides **19-59**
reduction of alcohols **19-54**
reduction of alkenes and alkynes **15-12**
reduction of alkyl halides **19-53**
reduction of anhydrides **19-65**
reduction of carbonyls to methylene **19-61**
reduction of carboxylic esters **19-65**
reduction of nitriles **19-66**
reduction of nitro compounds **19-67**
reduction of silanes **19-52**
reduction of sulfonate esters **19-57**
reduction of sulfur compounds **19-70**
reduction of thioethers **14-27**
reduction of thiols **14-27**
reduction of thiols **19-70**
reduction of xanthate esters **19-58**
reductive cleavage of cyclopropanes **15-15**
reductive cleavage of ethers **19-56**
replacement of metals in RM by hydrogen **12-24**
σ-bond rearrangements **18-38**
sulfonate esters + metals **10-56**
sulfonate esters + organocuprates **10-58**
sulfur compounds + organometallics **10-61**
via transmetallation **12-22**

ALKENE-ALCOHOLS
rearrangement of alkene-ethers **18-35**

ALKENE-ALDEHYDES
Claisen rearrangement **18-33**
Cope rearrangement **18-32**
rearrangement of allyl vinyl ethers **18-33**

ALKENE-ALKYNES
addition of alkynes to alkynes **15-20**

ALKENE-AMINES
rearrangement of alkene-ammonium salts **18-35**

ALKENE-CARBOXYLIC ACIDS
Claisen rearrangement **18-33**
rearrangement of alkene-esters **18-33**

ALKENE-KETONES
Claisen rearrangement **18-33**
rearrangement of allyl vinyl ethers **18-33**

ALKENE-THIOETHERS
rearrangement of alkene sulfonium salts **18-35**

ALKENES
aldehydes or ketones + active H compounds **16-38**
alkane addition to alkynes **15-18**
alkene addition\to alkenes **15-20**
alkene metathesis **18-37**
alkenes + aryl halides **13-10**
alkenes + arylboronic acids **13-10**
alkenes + aryldiazonium compounds **13-10**
alkenes + carbenes **15-64**
alkenes + carbocations **12-20**
alkynes + alkyl halides + RM (M = metal) **15-22**
alkynes + metals or metal hydrides **15-12**
allylic esters + RM **10-60**
allylic halides + metals **10-56**
allylic silanes + esters **10-60**
aryldiazonium salts + alkenes **13-26**
base induced elimination of halosulfones **17-20**
bis(decarboxylation) of dicarboxylic acids **19-13**
by [2 + 2]-cycloaddition **15-63**
by [3 + 2]-cycloaddition **15-59**
by decarboxylation **12-40**
by McMurry coupling **19-77**
by migration of double bonds **12-02**
by Peterson alkenylation **16-41**
by the Diels–Alder reaction **15-60**
by the ene reaction **15-23**
by the Heck reaction **13-10**
by the heteroatom Diels–Alder reaction **15-61**
by the Horner–Wadsworth–Emmons reaction **16-44**
by the Knoevenagel reaction **16-38**
by the Ramberg–Bäcklund reaction **17-20**
by the Sakurai reaction **15-26**
by the Wittig reaction **16-44**
cleavage of ethers **17-02**
cleavage of vinyl ethers **17-02**
conjugated addition of allylsilanes **15-26**
deacyloxylation **19-59**
decarbonylation of acyl halides **17-17**
decarboxylation of hydroxy-carboxylic acids **17-26**
dehydration of alcohols **17-01**
dehydrogenation **19-02**
deoxygenation of 1,2-diols **17-18**
deprotonation of episulfides (thiiranes) **17-03**
deprotonation of epoxides (oxiranes) **17-03**
diazoalkanes + aldehydes **15-64**
dimerization of alkyl halides **19-32**
elimination (1,3-) of diols **17-25**
elimination (1,3-) of haloamines **17-25**
elimination (1,3-) of halohydrins **17-25**
elimination (base) of ammonium salts **17-07**
elimination (base) of ammonium salts **17-08**
elimination (base) of halides **17-13**
elimination (base) of sulfonate esters **17-06**
elimination (base) of sulfonyl halides **17-14**
elimination (base) of sulfonyl hydrazones **17-11**
elimination of 1,2-dihalides **17-22**
elimination of boranes **17-15**
elimination of haloethers **17-24**
enamines + boranes **15-16**
esters + organometallics **10-60**
extrusion from oxathiolanes **17-38**
extrusion of CO from cyclic ketones **17-35**
from alcohols **10-63**
from alkenes **13-26**
from alkyl halides **10-55**
from allylic esters **10-60**
from bis(xanthates) **17-18**
from boranes **10-59**
from carbenes **12-21**
from dienes **18-37**
from episulfones **16-48**
from epoxides or thiiranes **17-03**
from imines **16-44**
from selenones **10-71**
from silanes **10-55**
hydroboration of alkynes **18-25**
hydrogenation of alkynes **15-11**

hydrogenation of aromatic compounds **15-13**
isomerization of double bonds **15-01**
ketones or aldehydes + bis(Grignards) **16-24**
migration of boranes **12-02**
migration of double bonds **12-02**
nitrosation of aziridines **17-21**
organometallics + ketones **16-25**
organometallics + tosylhydrazones **16-38**
other cycloaddition reactions **15-66**
oxidative decarboxylation of carboxylic acids **19-12**
Petasis alkenylation **16-45**
protonolysis of vinyl boranes **18-25**
protonolysis of vinyl boranes **18-26**
pyrolysis of amine oxides (Cope) **17-09**
pyrolysis of ammonium salts (Hofmann) **17-07**
pyrolysis of esters **17-04**
pyrolysis of hydroxy-alkenes **17-32**
pyrolysis of sulfones **17-12**
pyrolysis of sulfoxides **17-12**
pyrolysis of thionocarbonates **17-19**
pyrolysis of xanthates (Chugaev) **17-05**
pyrolysis of β-lactones **17-26**
rearrangement of dienes **18-39**
reduction of enamines **19-67**
reduction of hydrazones **19-61**
reduction of thiiranes **19-35**
reduction of thiophene derivatives **19-70**
reduction of vinyl halides **19-53**
reduction of vinyl imines **19-61**
reductive coupling of aldehydes or ketones **19-77**
reductive coupling of epoxides **19-35**
sigmatropic carbon migration **18-30**
sigmatropic H migration **18-29**
silyl-organometallics + aldehydes or ketones **16-41**
Tebbe alkenylation **16-45**
vinyl boranes + halogen/base **18-25**
vinyl halides + arylboronic acids **13-10**
vinyl-cyclopropane rearrangement **18-31**
vinyl-X + alkyl(aryl)boronic acids **12-15**
Wagner–Meerwein rearrangement of alcohols **18-01**
Wagner–Meerwein rearrangement of halides **18-01**

ALKYNE-ALCOHOLS
addition of alkynes to carbonyls **16-25**

ALKYNES
alkyl halides + alkyne anions **10-74**
alkyl halides + propargylic RM **10-57**
alkynes + aryliodonium salts **13-13**
alkynes + boranes **18-26**
aryl halides + alkyne-M (M = a metal) **13-13**
aryl halides + alkynes **10-74**
base-induced isomerization alkynes **12-02**
dimerization of dihalides **19-32**
elimination of alkenes **17-16**
elimination of dihalo compounds (by base) **17-16**
elimination of halides (by base) **17-13**
from alkyl halides **10-74**
from alkynes **10-74**
hypervalent iodine + alkyne-M (M = a metal) **12-26**
metathesis of alkynes **18-37**
pyrolysis of bis(ammonium)salts **17-07**
pyrolysis of thiirene dioxides **17-20**
pyrolysis of ylids **17-10**
Sonogashira coupling **13-13**
Stephens–Castro coupling **13-13**

ALLENES
base-induced rearrangement of halocyclopropanes **18-03**
by Claisen rearrangement **18-33**
by the Wittig reaction **16-44**
Cope rearrangement of diynes **18-32**
elimination of dihalides **17-22**
propargylic esters + organocuprates **10-60**
reduction of alkynes **19-53**

ALLOPHANATES
carbamates + isocyanates **16-08**

AMIDE–ESTERS
aziridines + amides **10-14**

AMIDES
acyl halides + ammonia or amines **16-72**

addition of organometallics to isocyanates **16-33**
alcohols + cyanogen halides **16-09**
aldehydes + ammonia + oxidant **14-11**
alkanes + nitriles **14-12**
alkenes + amides **15-09**
alkenes + nitriles **16-91**
alkyl halides + amides **10-41**
amides + aldehydes **10-41**
amides + amines **16-76**
amines + CO + alkenes **15-36**
amines + CO **12-53**
amines + haloformates **10-53**
amines + organoiron compounds **10-77**
amines + vinyl esters **16-75**
anhydrides + ammonia or amines **16-73**
aromatic compounds + amides **11-22**
aromatic compounds + hydroxamic acids **11-06**
aromatic compounds + isocyanates **11-21**
aryl halides + amides **10-41**
aryl halides + amides **13-05**
aryl halides, DMF and $POCl_3$ **11-21**
by Beckmann rearrangement **18-17**
by Michael addition **15-24**
by Mitsunobu reaction **10-41**
by reaction with nitrenes **12-13**
by the Haller–Bauer reaction **12-46**
by the Willgerodt reaction **19-84**
carboxylic acids + amino-boranes **16-74**
carboxylic acids and ammonia or amines **16-74**
carboxylic esters + ammonia or amines **16-75**
cleavage of ketones **12-46**
condensation of methyl ketones **19-84**
dealkylation of amides **19-73**
from alcohols **10-41**
from aromatic compounds **11-19**
from *N*-halo amides **11-31**
hydrolysis of isonitriles **16-97**
hydrolysis of nitriles **16-04**
imines + borane + CO **12-33**
insertion of acyl nitrenes **12-13**
insertion of diazo amides **12-21**
ketenes + amines **15-08**
ketones + HN_3 **18-16**
ketones + $^{-}NH_2$ **12-46**
N-alkylation **10-41**
N-arylation **10-41**
nitriles + alcohols **16-91**
nitriles + amines **16-21**
oxidation of methylene in amines **19-17**
oximes + halogenating or oxidizing agents **18-17**
pyrolysis of imino esters **18-42**
rearrangement of oximes **18-17**
reduction of imides **19-64**
Ritter reaction **16-91**
transamidation **16-70**

AMIDES, CONJUGATED
isocyanates + vinyl-M (metal) **15-22**

AMIDINES
ketenimines + amines **15-08**
nitriles + ammonia or amines **16-21**

AMIDO-ALCOHOLS
alkenes + amides **15-52**

AMINE OXIDES
oxidation of amines **19-29**

AMINES
addition of organometallics to C=N compounds **16-31**
addition of silanes to C=N **16-31**
alkenes + amines or ammonia **15-08**
alkyl halides + amines **10-31**
alkylation of amines **10-31**
alkylation of formamidines **10-71**
alkylation of nitroso amines **10-71**
allylic amination **12-12**
amides + organometallic compounds **16-82**
amination of active methylene compounds **12-12**
amination of alkanes **10-39**
amination of alkanes **12-12**
amination of heterocycles **13-18**
amination of methylene **19-16**
amines + aryl halides **13-05**
amines + diaryliodonium compounds **11-06**
amines + diazo compounds **10-34**

aminomethylation of aromatic compound **11-22**
aromatic compounds + amide bases **13-18**
aromatic compounds + aryl azides **11-06**
aromatic compounds + haloamines **11-06**
aromatic compounds + hydrazoic acid **11-06**
aryl halides + amines **13-05**
aryl halides + hydroxylamine-*O*-sulfonic acid **18-15**
azides + haloboranes **12-32**
aziridines + RM **10-66**
boranes + ammonia + NaOCl **12-32**
boranes + chloramine **12-32**
by amidomethylation **11-22**
by reaction with nitrenes **12-13**
by the Stevens rearrangement **18-21**
by transamination **10-33**
Curtius rearrangement **18-14**
cyclization of haloamines **18-40**
dealkylation of amines **19-73**
dehydrogenation **19-02**
displacement of cyano **10-62**
diynes + amines **15-08**
enamines + boranes **15-16**
from alcohols **10-31**
from alcohols **10-32**
from alkanes **10-39**
from amides **18-13**
from amines **10-31**
from amines **10-33**
from amines **10-34**
from amines **10-71**
from amino-ethers **10-64**
from amino-nitriles **10-62**
from ammonium salts **11-32**
from boranes **10-31**
from cyanohydrins **10-32**
from ethers **10-32**
from haloamines **10-31**
from hydrazones **10-71**
from hydroxylamines **13-32**
from nitroamines **11-28**
from nitrosamines **11-29**
from organometallics **12-32**
from phenols **11-22**
from phenols **13-06**
Hofmann rearrangement **18-13**
Hofmann–Löffler reaction **18-40**
hydrolysis of isocyanates **18-13**
hydrolysis of isocyanates **18-15**
hydrolysis of isocyanates **18-16**
hydroxylamines + alkyl organometallics **12-32**
imines + allylic silanes **16-51**
insertion of nitrenes **12-13**
Lossen rearrangement **18-15**
Michael addition with N nucleophiles **15-31**
phenols + amines or ammonia **13-06**
Pictet–Spengler reaction **10-13**
radical addition to C=N compounds **16-56**
rearrangement of ammonium salts **13-31**
rearrangement of ammonium salts **18-21**
rearrangement of aryl hydroxylamines **13-32**
reduction nitroso compounds **19-47**
reduction of amides **19-64**
reduction of amine oxides **19-68**
reduction of amines **19-64**
reduction of azides **19-50**
reduction of azo compounds **19-74**
reduction of azoxy compounds **19-74**
reduction of C=N compounds **19-42**
reduction of hydrazines **19-74**
reduction of hydroxylamines **19-47**
reduction of isocyanates **19-51**
reduction of isothiocyanates **19-51**
reduction of lactams **19-64**
reduction of nitriles **19-43**
reduction of nitro compounds **19-45**
reduction of nitrosoamines **19-51**
reduction oximes **19-48**
reductive alkylation of aldehydes or ketones **16-17**
Schmidt reaction **18-16**
Sommelet–Hauser rearrangement **13-31**
Stevens rearrangement **13-31**
transamination **10-33**

AMINO ACIDS
lactones + ammonia or amines **16-75**

AMINO ALCOHOLS
alkenes + amines **15-52**
epoxides + amines or ammonia **10-35**
from amino epoxides **10-36**
from isonitriles **10-40**
from nitroalcohols **10-35**
oxetanes + amines or ammonia **10-37**
rearrangement of haloamines **18-10**
reductive coupling of C=N with C=O **19-76**

AMINO ALDEHYDES
aldehydes + C=N compounds **16-31**

AMINO ESTERS
diazoesters + amines **15-64**

AMINO ETHERS
aziridines + alcohols **10-14**

AMINO KETONES
base-induced rearrangement of sulfonyl oximes **18-12**
ketones + HCHO + amines **16-19**
Mannich reaction **16-19**

AMINO NITRILES
from amines **12-19**
from cyanohydrins **10-32**
HCN or cyanide + C=N compounds **16-53**

AMINO THIOETHERS
alkenes + sulfonamides **15-55**
alkenes + sulfonium salts + amines **15-55**

AMINO THIOLS
episulfides + amines or ammonia **10-35**

AMMONIUM SALTS
alkyl halides + amines **10-31**

ANHYDRIDES
acyl halides + carboxylic acids **16-66**
aldehydes + acyl peroxides **14-09**
carboxylic acids + vinyl esters **16-67**
dehydration of carboxylic acids **16-67**
dehydration of dicarboxylic acids **16-67**

ANHYDRIDES, ORGANIC–INORGANIC
anhydrides + mineral acids **16-68**

ARENES
alkyl halides + ArM (Li, Na, K) **10-57**
alkyl halides + aryl organometallics **10-57**
alkyl halides + arylboronic acids **13-09**
alkyl halides + organocuprates **10-58**
alkyl halides + organometallics **13-17**
aromatic compounds + active H compounds **13-17**
aromatic compounds + acylperoxides **14-17**
aromatic compounds + alcohols **11-11**
aromatic compounds + alkenes **11-11**
aromatic compounds + alkyl halides **11-11**
aromatic compounds + carboxylic acids **14-19**
aromatic compounds + ketones **11-12**
aromatic compounds + peroxides **14-17**
aryl halides + active methylene compounds **13-14**
aryl halides + alkenes **13-10**
aryl halides + alkenes **15-21**
aryl halides + alkynes **15-21**
aryl halides + organocuprates **10-58**
aryl halides + RM (other metals) **10-59**
aryl halides + trifluoroborates **13-09**
aryl halides + vinylboronic acids **13-09**
aryldiazonium salts + alkenes **13-26**
aryldiazonium salts + alkyl organometallics **13-25**
aryldiazonium salts + organometallics **13-25**
by decarboxylation **12-40**
by radical cyclization **15-30**
coupling of aromatic compounds **11-15**
cyclodehydration of carbonyl compounds **11-13**
Friedel–Crafts alkylation **11-11**
from alkylborates **10-59**
from boranes **10-59**
from ketones **11-13**
hydrogen exchange **11-01**
rearrangement of *N*-alkyl aryl amines **11-32**

replacement of aryl nitro **13-29**
α-halo ketones + organocuprates **10-58**

AROMATIC COMPOUNDS
alkylation of heteroaryls **14-19**
aromatic compounds + carbenes **15-64**
aromatization of six-membered rings **19-01**
cleavage of arenes **11-33**
cleavage of aryl alkyl ethers **11-37**
cyclization of ene–diynes **18-27**
cyclotrimerization of alkynes **15-65**
deamination of aromatic compounds **19-69**
decarbonylation of aryl aldehydes **11-34**
decarboxylation of aryl carboxylic acids **11-35**
dehalogenation of aryl halides **11-39**
dehydrogenation of cyclic alkanes **19-01**
deoxygenation of aryl ethers **11-37**
desulfonylation of aryl sulfonic acids **11-38**
from aldehydes **11-34**
from aromatic compounds **11-33**
from aromatic compounds **18-28**
hydrolysis of aromatic organometallics **11-41**
protonation of aryl organometallics **11-41**
pyrolysis of bicyclic dienones **17-28**
reduction aryl diazonium salts **19-69**
reduction of aryl halides **11-39**
reduction of phenols **19-55**
reduction of quinones **19-01**

AZIDES
aldehydes + metal azides **16-78**
alkenes + hydrazoic acid **15-10**
alkenes + metal azides **15-53**
amides + sulfonyl azides **12-11**
from acyl halides **10-43**
from alkyl halides **10-43**
hydrazines + HONO or nitrosyl compounds **12-49**

AZIDO ALCOHOLS
from epoxides **10-43**

AZIDO AMIDES
from amides **12-11**

AZIDO AMINES
from aziridines **10-38**

AZIRIDINES
alkenes + alkyl azides **15-54**
alkenes + halogen + haloamines **15-54**
C=N compounds + sulfur ylids **16-47**
extrusion of nitrogen from triazolines **17-34**
form haloamines **10-31**
from allene amides **15-09**
from azido alcohols **10-43**
from epoxides **10-36**
from halo-azides **15-45**
from hydroxy-amines **10-32**
from imines **16-32**
from triazolines **15-58**
imines + diazo compounds **16-32**

AZIRINES
alkynes + amino nitrenes **15-54**

AZO COMPOUNDS
aryl amines + nitroso compounds **13-24**
aryl diazonium salts + aromatic compounds **11-04**
from aryldiazonium salts **13-28**
oxidation of hydrazines **19-05**
rearrangement of aryl triazenes **11-30**
rearrangement of azoxy compounds **18-43**
reduction of azoxy compounds **19-68**
reduction of nitro compounds **19-80**
Wallach rearrangement **18-43**

AZOXY COMPOUNDS
from alkyl halides **10-45**
nitroso compounds + hydroxylamines **12-51**
reduction of nitro compounds **19-79**

BIARYLS
aromatic compounds + aryl halides (*hν*) **14-18**
aromatic compounds + aryl organometallics **11-16**

aromatic compounds + aryl organometallics **14-17**
aromatic compounds + arylboronates **11-16**
aryl halides + alkyl or aryl organometallics **13-09**
aryl halides + arylboronic acids **13-09**
aryl halides + arylboronic acids **13-12**
aryl halides + metals **13-11**
aryl halides + trifluoroborates **13-12**
aryldiazonium salts + aromatic compounds **13-27**
aryldiazonium salts + metal salts **13-28**
arylsulfonic acid + arylboronic acids **13-05**
by benzidine rearrangement **18-36**
coupling 2 aryldiazonium salts **13-28**
coupling aryl halides **13-11**
coupling of aromatic compounds **11-15**
coupling of aryl sulfonates **13-12**
Scholl Reaction **11-15**
Suzuki–Miyaura coupling **13-12**
Ullmann coupling **13-11**

BIS(AMINES)
by benzidine rearrangement **18-36**

BIS(AMIDES)
aldehydes + amides **16-18**

BISULFITES
metal bisulfite + carbonyl compounds **16-12**

BORANES
alkenes + borane or alkyl boranes **15-16**
thermal migration of boron in boranes **18-11**

BORATES (TRIFLUORO)
boranes + KHF_2 **12-28**

BORATES
alcohols + boranes **12-28**
oxidation of boranes **12-27**

BORONIC ACIDS
alkyl borates + alkyl organometallics **12-28**

BUNTE SALTS
from alkyl halides **10-28**

CARBAMATES
alkyl halides + amines **10-17**
amines + alkyl halides + CO_2 **12-53**
amines + CO_2 **12-53**
from aziridines **12-53**
haloformates + amines **16-72**
isocyanates + alcohols **16-08**

CARBONATES
alcohols + phosphine **16-10**

CARBOXYLIC ACIDS
acyl halides + diazo compounds **18-08**
acyl peroxides + alkyl organometallics **12-26**
alkylation of carboxylic acids **10-70**
aromatic compounds + CO_2 **11-20**
aromatic compounds + CO_2 **11-20**
aromatic compounds-carboxylation **11-19**
aryl nitro compounds + cyanide **13-30**
Barbier–Wieland procedure **19-10**
boranes + ether-acids **18-24**
by decarboxylation **12-40**
by Favorskii rearrangement **18-07**
by malonic ester synthesis **10-67**
by Michael addition **15-24**
by the Cannizzaro reaction **19-81**
carboxylation of alkenes **15-35**
cleavage of diketones **12-43**
cleavage of ketoesters **12-43**
cleavage of ketones **12-45**
cleavage of methyl ketones **12-44**
deacyloxylation **19-59**
esters + metal halides **10-51**
from carboxylic acids **10-70**
from lactones **10-51**
from oxazolones **10-72**
from RM + arenes **10-57**
haloform reaction **12-44**
hydrolysis of acyl halides **16-57**
hydrolysis of amides **16-60**
hydrolysis of anhydrides **16-58**
hydrolysis of carboxylic esters **16-59**
hydrolysis of diazo ketones **18-08**
hydrolysis of nitriles **16-04**

hydrolysis of ortho esters **10-06**
hydrolysis of trihalide **10-03**
ketones + peroxy acids **18-19**
organometallics + CO_2 **16-30**
oxidation of aldehydes **19-23**
oxidation of aromatic rings **19-10**
oxidation of aromatic side chains **19-11**
oxidation of organoiron compounds **10-77**
oxidation of primary alcohols **19-22**
oxidative cleavage of alkenes **19-10**
oxidative cleavage of alkynes **19-10**
ozonolysis of alkenes **19-09**
phenoxides + CO_2 **11-20**
phosphoranes + CO_2 **16-44**
pyrolysis of esters **17-04**
rearrangement of ketones **18-19**

CARBOXYLIC ACIDS, CONJUGATED
aldehydes + anhydrides **16-39**
by the Knoevenagel reaction **16-38**
CO_2 + vinyl-M (metal) **15-22**

CARBOXYLIC ESTERS
acyl halides + alcohols **16-61**
acyl halides + ethers **16-61**
alcohols + CO + alkenes **15-36**
alcohols + CO + alkyl halides **10-77**
alcohols + ketenes **15-05**
alcohols + organoiron compounds **10-77**
alcoholysis of acyl oxazolidinones **16-65**
alcoholysis of amides **16-65**
alcoholysis of nitriles **16-09**
alcoholysis of trihalides **10-03**
alkenes + acyl peroxides **14-09**
alkenes + carboxylic acids **15-06**
alkenes + carboxylic esters **15-33**
alkyl halides + carboxylate anions **10-17**
alkylation of oxazolidines **10-72**
allylic carbonates + malonates **10-60**
allylic esters + malonates **10-60**
anhydrides + alcohols **16-62**
aryl halides + alcohols + CO **13-15**
aryl halides + alcohols + metal carbonyls **13-15**
Baeyer–Villiger rearrangement **18-19**
by Favorskii rearrangement **18-07**
by Michael addition **15-24**
by the Tishchenko reaction **19-82**
carbonylation of alkyl halides and alcohols **10-77**
carboxylic acids + diazo compounds **10-19**
cleavage of keto-esters **12-43**
condensation of aldehydes **19-82**
condensation of ketones **19-84**
conjugate addition of allylic silanes **15-26**
esterification of carboxylic acids **16-63**
esters + ethers **10-18**
ethers + anhydrides **10-18**
from alcohols **10-77**
from alkanes **14-09**
from alkyl halides **10-17**
from alkyl halides **10-77**
from alkyl halo sulfites **10-17**
from carboxylate salts **10-17**
from coupling of activated esters **10-61**
from onium salts **10-17**
from peroxides **14-09**
from tosyl amides **10-17**
hydrolysis of ortho esters **10-06**
insertion of diazo esters **12-21**
ketones + peroxides **18-19**
oxidation of aldehydes **19-23**
oxidation of methylene in ethers **19-17**
oxidation of primary alcohols **19-22**
oxidation of vinyl ethers **19-25**
oxidative decarboxylation **19-12**
oxygenation of organometallics **12-29**
Pinner synthesis **16-09**
rearrangement of haloketones **18-07**
ring contraction of diazoketones **18-08**
Sakurai reaction **15-26**
transesterification **16-64**
via Mitsunobu coupling **10-17**

CARBOXYLIC ESTERS, CONJUGATED
Baylis–Hillman reaction **16-27**
by the Knoevenagel reaction **16-38**
Claisen condensation **16-36**

COUMARINS
from phenols **11-11**

CUMULENES
elimination of propargylic halides **17-22**

CYANAMIDES
amines + cyanogen halides **10-54**

CYANATES, ARYL
phenols + cyanogen halides **10-08**

CYANIDES, ACYL
acyl halides + metal cyanides **16-88**

CYANO IMINES
nitroso compounds + nitriles **16-42**

CYANOAMINES
see amino nitriles

CYANOHYDRINS
aldehydes or ketones + HCN **16-52**
aldehydes or ketones + R_3SiCN **16-52**

CYCLOBUTANES
by [2 + 2]-cycloaddition **15-63**
extrusion of SO_2 **17-36**

CYCLOBUTENES
ring closure of dienes **18-27**

CYCLOPROPANES
alkenes + carbenes **15-64**
alkenes + diazo esters **15-58**
by the Simmons–Smith reaction **15-64**
conjugated carbonyls + sulfur ylids **16-49**
extrusion of nitrogen from pyrazolines **17-34**
extrusion off CO from cyclobutanones **17-35**
from pyrazoles **17-34**
from pyrazolines **15-58**
rearrangement of dienes **18-39**

DIACETATES
oxidation of dicarboxylic acids **19-13**

DIALDEHYDES
alkylation reactions **10-67**

DIAMINES
aziridines + amines or ammonia **10-38**
diamination of alkenes **15-53**
from azido amines **10-38**
reductive coupling of imines **19-76**

DIAZO COMPOUNDS
acyl halides + diazomethane **16-89**
base-induced elimination of *N*-nitroso compounds **17-33**
from active methylene compounds **12-10**
oxidation of hydrazones **19-06**

DIAZONIUM COMPOUNDS
active methylene compounds + sulfonyl azides **12-10**
aldehydes + sulfonyl azides **12-10**
aromatic compounds + HONO **11-05**
aryl amines + HONO **13-19**

DICARBOXYLIC ACIDS
by Michael addition **15-24**
from aryl isothiocyanates **11-21**
oxidative cleavage of cyclic alkenes **19-10**
oxidative cleavage of ketones **19-08**

DIACIDS, CONJUGATED
by the Knoevenagel reaction **16-38**

DIENES
addition of alkenes to dienes **15-20**
addition of alkynes to alkynes **15-20**
allylic halides + metals **10-56**
by Stille coupling **12-15**
by the Diels–Alder reaction **15-60**
by the Wittig reaction **16-44**
cleavage of cyclobutanes **15-63**
Cope rearrangement **18-32**
coupling of alkynes and allenes **15-20**
coupling vinyl boranes **14-26**
cycloaddition of dienes **15-66**
dehydration of alkyne-alcohols **17-01**
dienes + acyl metal compounds **12-16**
elimination of halides **17-22**
from aromatic compounds **18-27**
from vinyl compounds **12-15**
hydrogenation of aromatic compounds **15-13**
hydrogenation of diynes **15-11**

metathesis of alkenes **18-37**
other cycloaddition reactions **15-66**
pyrolysis of bicyclic alkene-ketones **17-28**
pyrolysis of sulfoxides **17-20**
rearrangement of dienes **18-32**
ring closure of trienes **18-27**
ring opening of cyclic alkenes **18-27**
sigmatropic carbon migration **18-30**
sigmatropic H migration **18-29**
vinyl halides + metals **10-56**
vinyl halides + RM (other metals) **10-59**
vinyl-X + vinyl-M **12-15**

DIESTERS
active methylene compounds + alkyl halides **10-67**
alkenes + acyloxy salts **15-56**
alkylation reactions **10-67**
arylation **13-14**
dimerization of acetals **10-64**

DIHALIDES (GEMINAL)
alkenes + halogenating agents **16-23**
ketones + halogenating agents **16-23**

DIHALIDES
alkynes + HX **15-02**
dihalogenation of alkenes **15-39**
from alkyl halides + trihalides **10-57**

DIIMIDES
isocyanates + phosphine oxides **16-93**

DIKETONES
acyl halides + active H compounds **16-84**
acylation of enamines **10-69**
alkylation reactions **10-67**
arylation **13-14**
by Michael addition **15-24**
conjugate addition of acyl halides **15-32**
conjugate addition of RM with metal carbonyls **15-32**
conjugated ketones + metals **10-56**
coupling acyl halides **16-83**
dimerization of silyl enol ethers **19-33**
esters + ketones **16-86**
from dithioketals **16-86**
hydrolysis of furans **10-06**
ketones + diazoketones **12-21**
oxidation of alkynes **19-26**
oxidation of methylene **19-17**
oxidative cleavage of cyclic alkenes **19-10**

DIKETONES, CONJUGATED
by the Knoevenagel reaction **16-38**

DINITRILES
alkylation reactions **10-67**
arylation **13-14**

DIOLS
alkenes + formaldehyde **16-54**
alkenes + halogens + metal carboxylates **15-48**
by the Tollens reaction **16-43**
dihydroxylation of alkenes **15-48**
from halo-esters **15-48**
hydride shifts of epoxides **18-41**
hydrolysis of epoxides **10-07**
ketones + formaldehyde **16-43**
oxidation of aromatic compounds **15-49**
pinacol coupling **19-76**
reduction of lactones **19-38**
reductive coupling of aldehydes or ketones **19-76**

DISULFIDES
aryl halides + sulfides **13-04**
from alkyl halides **10-27**
oxidation of thiols **19-34**
reduction of sulfonyl halides **19-71**

DITHIOACETALS
aldehydes + thiols **16-11**
from dihalides **10-26**

DITHIOCARBAMATES
amines + carbon disulfide **16-22**

DITHIOKETALS
alkylation of dithioketals **10-71**
from dithioketals **10-13**
from dithiols **10-13**
ketones + CS_2 **16-42**
ketones + thiols **16-11**
vinyl sulfides + thiols **15-07**

DITHIOLS
alkenes + sulfur reagents **15-51**

DIYNES
by Cadiot–Chodkiewicz coupling **14-16**
by Glaser coupling **14-16**
by Sonogashira coupling **14-16**
from alkynyl boronates **14-16**
metal coupling of alkynes **13-13**
metal coupling of alkynes **14-16**

ENAMIDES
amines + vinyl halides **12-32**

ENAMINES
alkylation of enamines **10-71**
alkynes + amines **15-08**
from hydroxy-amines **16-13**

ENOL ETHERS: See vinyl ethers

ENOLS
and keto–enol tautomerism **12-03**

EPISULFIDES: See thiiranes

EPOXIDES (Oxiranes)
aldehydes or ketones + haloorganometallics **16-24**
diazonium compounds + aldehydes or ketones **16-46**
epoxidation of alkenes **15-50**
from halohydrins **10-09**
ketones + alkenes **16-95**
sulfur ylids + aldehydes or ketones **16-46**

EPOXY ALCOHOLS
allylic alcohols + peroxides **15-50**
from epoxy alcohols **10-14**

EPOXY AMIDES
epoxidation of conjugated esters **15-50**

EPOXY CARBOXYLIC ACIDS
epoxidation of conjugated acids **15-50**

EPOXY ESTERS
diazo esters + aldehydes **15-64**
epoxidation of conjugated esters **15-50**
halo esters + aldehydes or ketones **16-40**

EPOXY KETONES
epoxidation of conjugated ketones **15-50**

EPOXY NITRILES
epoxidation of conjugated nitriles **15-50**

ESTER AMIDES
isonitriles + carboxylic acids + aldehydes **16-98**
isonitriles + carboxylic acids + ketones **16-98**

ESTER SULFIDES
by the Pummerer rearrangement **19-83**
rearrangement of sulfoxides **19-83**

ESTERS: See Carboxylic Esters

ESTERS, INORGANIC
from alcohols **10-22**
from sulfonyl halides **10-22**
phosphites + alkyl halides **16-44**

ESTERS, SULFONIC (see SULFONATE)

ETHER AMINES
rearrangement of halo-amines **18-18**

ETHER ESTERS
conjugated esters + alcohols **15-05**

ETHER KETONES
acetals + vinyl ethers **10-64**
oxidation of methylene **19-15**

ETHERS
acyl peroxides + alkyl organometallics **12-26**
alcohols + diazo compounds **10-11**
alcohols + ethers **10-13**
alcohols + onium salts **10-15**

alcohols + sulfonate esters **10-10**
aldehydes + alcohols **16-07**
alkenes + alcohols **15-05**
alkenes-alkoxymercuration **15-05**
alkylation of ethers **10-71**
aryl halides + alkoxides **13-03**
cleavage of oxonium salts **10-49**
coupling of silanes **14-15**
dehydration of alcohols **10-12**
from alcohols (Williamson ether synthesis) **10-08**
from alcohols + phenols **10-12**
from alcohols **14-06**
from alkyl halides (Williamson ether synthesis) **10-08**
from alkyl halides **10-10**
from alkyl sulfates **10-10**
from carboxylic esters **10-10**
from dihalides **10-10**
from ethers **10-13**
from haloethers **10-08**
from halohydrins **10-09**
from lactones and organometallics **16-30**
from phenols **13-33**
from trichloroimidates **10-10**
ketones + alcohols **16-07**
Michael addition with O nucleophiles **15-31**
Organometallics + peroxides **12-26**
oxidative cyclization of alcohols **14-06**
phenols + diazo compounds **10-11**
rearrangement of aryl sulfones **13-33**
reduction of esters **19-62**
reduction of lactones **19-62**
reductive cleavage of acetals or ketals **19-56**
Smiles rearrangement **13-33**
transetherification **10-13**

ETHERS, SILYL
Brook rearrangement **18-44**
cleavage of ethers **10-49**
from alcohols and silyl halides **10-08**
rearrangement of hydroxy-silanes **18-44**

FORMAMIDES
amines + trihalides **10-40**

GLYCIDIC ESTERS: See epoxy esters

HALIDES, ACYL
acyl halides + HF **16-80**
aldehydes + halogens **14-04**
anhydrides + HF **16-80**
carboxyl acids + halogenating agents **16-79**
oxidation of primary alcohols **19-22**

HALIDES, ALKYL
alcohols + HX **10-48**
alcohols + inorganic acid halides **10-48**
aldehydes + halo-boranes **16-23**
alkanes + halogenating reagents **14-01**
alkenes + alkyl halides **15-46**
alkenes + halogenating agents **14-03**
alkenes + HX **15-02**
carboxylate salts + halogens **14-30**
cleavage of amides **10-53**
cleavage of amines **10-53**
cleavage of ethers **10-49**
cleavage of oxonium salts **10-49**
from alcohols **10-48**
from aldehydes + aromatics **10-14**
from alkyl halides **10-46**
from amines **10-53**
from esters **10-51**
from inorganic esters **10-47**
from silyl ethers **10-48**
from sulfonate esters **10-47**
halide exchange with alkyl halides **10-46**
halo-decarboxylation of acids **16-71**
halogens + alkyl organometallics **12-31**
halogens + boranes **12-31**
halo-methylation of arenes **11-14**
Hunsdiecker reaction **14-30**

HALIDES, ALLYLIC
alkanes + halo-succinimides **14-03**
alkenes + halogens **14-03**

HALIDES, ARYL
aromatic compounds + halogen **11-10**
aromatic compounds + halo-succinimides **11-10**
aryl ammonium salts + halide ion **11-32**
aryl halides + halogenating agent **13-07**

aryldiazonium salts + metal halides **14-20**
aryldiazonium salts + metal iodides **13-22**
by Sandmeyer reaction **14-20**
from aryl amines **14-20**
from phenols **13-22**
heating aryldiazonium tetrafluoroborates **13-23**
phenols + phosphonium halides **13-07**
rearrangement of *N*-haloamides **11-31**
sulfonyl halides + transition metal halides **11-38**

HALIDES, Silyl
From silanes **14-02**

HALIDES, SULFONYL
alkanes + SO_2 + halogens **14-10**
aromatic compounds + sulfonyl halides **11-08**
aryldiazonium salts + sulfur dioxide **14-22**
sulfonic acids + halogenating agents **16-103**

HALIDES, VINYL
elimination of dihalides **17-22**
elimination of halides (by base) **17-13**
from aldehydes or ketones **11-23**
from alkynes **12-31**
halide exchange with vinyl halides **10-46**
halogens + vinyl boranes **12-31**
halogens + vinyl-M (M = a metal) **12-31**

HALOALCOHOLS (Halohydrins)
cleavage of cyclic ethers **10-49**
from aldehydes or ketones **16-24**

from alkenes **15-40**

HALOALDEHYDES
aldehydes + halogen **12-04**
aldehydes + halogenating agent **12-04**
alkenes + formamides **15-47**

HALOALKYNES
from alkynes **12-31**

HALOAMIDES
from amides **12-53**
from aziridines **10-50**

HALOAMINES
alkenes + *N*-haloamines **15-43**
from amines **12-52**

HALOAZIDES
alkenes + X-N_3 **15-45**

HALOCARBOXYLIC ACIDS
carboxylic acid + halogen **12-05**
carboxylic acid + halogenating agents **12-05**
from amino acids **10-52**

HALOESTERS
from epoxides **10-50**

HALOETHERS
from alkene-alcohols **15-51**

HALOKETONES
alkenes + acyl halides **15-47**
from diazoketones **10-52**
from enol borinates **12-04**
ketone + halogen **12-04**
ketone + halogenating agents **12-04**

HALOLACTAMS
halolactamization **15-41**

HALOLACTONES
halolactonization **15-41**

HALONITRO COMPOUNDS
alkenes + NOX **15-44**

HALONITROSO COMPOUNDS
alkenes + NOX **15-44**

HALOSILANES
from silanes **10-16**
silanes + halogens **14-02**

HALOSULFONES
sulfones + halogenation agents **12-06**

HALOSULFOXIDES
sulfoxides + halogenating agents **12-06**

HALOHYDRINS
alkenes + alcohols + halogens **15-40**
alkenes + hypohalous acids **15-40**
from epoxides **10-50**

HETEROCYCLES
acylation of amines **16-77**
aromatization of six-membered rings **19-01**
by [3 + 2]-cycloaddition **15-58**
by the heteroatom Diels–Alder reaction **15-61**
by the Paterno–Büchi reaction **15-63**
condensation of aldehydes **16-92**
cyclization of amino-ketones or aldehydes **16-13**
cyclization of haloamines **18-40**
dehydrogenation reactions **19-02**
dinitriles + ammonia or amines **16-21**
rearrangement of acyl aziridines **18-31**
thermal rearrangement of azides **18-14**
furans: from diketones **16-05**
indoles: Fischer indole synthesis **18-34**
oxetanes: alkenes + aldehydes or ketones **16-95**
oxetanes: Paterno–Büchi reaction **16-95**
oxetanes: alkenes + ketones **15-63**
pyrans: from diketones **16-05**
pyrazoles: hydrazines + diketones **16-14**
pyrazolines: alkenes + diazoalkanes **15-58**
pyrazolines: hydrazines + keto-esters **16-14**
pyridine derivatives: by the heteroatom Diels–Alder reaction **15-61**
pyrrazolidines: alkenes + azomethine imines **15-58**
pyrrolidines: cleavage of aziridines **15-58**
pyrrolines: rearrangement of cyclopropyl imines **18-31**
quinolines (dihydro): cyclodehydration of imines **11-13**
quinolines (dihydro): from amines **11-13**
quinolines (tetrahydro): cyclodehydration of amides **11-13**
quinolines (tetrahydro): from amines **11-13**

HYDRATES
from ketones or aldehydes **16-01**

HYDRAZIDES
Imides + hydrazine **10-41**
carboxylic esters + hydrazine **16-75**

HYDRAZINES
reduction of azo compounds **19-51**
reduction of diazo compounds **19-51**

HYDRAZONES
active methylene compounds + aryldiazonium **12-07**
exchange of hydrazine + hydrazones **16-14**
from azo compounds **12-07**
from ketones **12-07**
hydrazines + aldehydes or ketones **16-14**

HYDROXAMIC ACIDS
carboxylic esters + hydroxylamine **16-75**

HYDROXY-ALDEHYDES
aldol condensation **16-34**
dihydrooxazines + epoxides **10-72**
imines + ketones **16-34**
Mukaiyama aldol **16-35**
oxidation of epoxides **19-20**
silyl enol ethers + aldehydes **16-35**

HYDROXY-AMIDES
aldehydes + amides **16-18**
alkenes + amides **15-52**
alkenes + sulfonyl amines **15-52**

HYDROXY-AMINES: See amino alcohols

HYDROXY-AZIRIDINES
from amino epoxides **10-36**

HYDROXY-CARBOXYLIC ACIDS
by the Cannizzaro reaction **19-81**
rearrangement of 1,2-diketones **18-06**

HYDROXY-ESTERS
Baylis–Hillman reaction **16-27**

Claisen condensation **16-36**
epoxides + carboxylate anions **10-14**
from epoxides and RCOOH **10-18**
Reformatsky reaction **16-28**
transesterification of lactones **16-64**

HYDROXY-ETHERS
epoxides + alcohols **10-14**

HYDROXY-KETONES
acyloin condensation **19-78**
aldehydes + cyanide **16-55**
aldehydes and cyanide **15-32**
Baylis–Hillman reaction **16-27**
by aldol condensation **16-34**
by rearrangement of hydroxy ketones **18-04**
by the Tollens reaction **16-43**
coupling of carboxylic esters **19-78**
hydrolysis of diazo ketones **10-05**
ketones + formaldehyde **16-43**
Mukaiyama aldol **16-35**
oxidation epoxides **19-20**
oxidation of methylene **19-15**
photolysis of epoxy ketones **10-07**
rearrangement of silyloxy epoxides **18-02**
reduction of epoxy ketones **19-35**
silyl enol ethers + ketones **16-35**

HYDROXY-NITRILES: See cyanohydrins

HYDROXY-NITRO COMPOUNDS
from epoxides **10-35**
Henry reaction **16-37**

HYDROXY-PHOSPHONATES
phosphonate esters + carbonyl compounds **16-44**

HYDROXY-PHOSPHORAMIDES
phosphoramides + carbonyl compounds **16-44**

HYDROXY-THIOCYANATES
epoxides + thiocyanate **10-14**

HYDROXY-THIOETHERS
alkenes + disulfides + carboxylic acids **15-51**
Claisen condensation **16-36**
from epoxides **10-26**

HYDROXYLAMINES
addition of organometallics to oximes **16-31**
oxidation of amines **19-27**
rearrangement of amine oxides **18-21**
reduction of nitro compounds **19-46**

IMIDES
acylation of amines **16-77**
alkyl halides + imides **10-41**
anhydrides + ammonia or amines **16-73**
from alcohols **10-41**
from aryl acyl isothiocyanates **11-21**
isocyanates + phosphine oxides **16-93**

IMIDINES
dinitriles + ammonia or amines **16-21**

IMINES
active methylene compound + nitroso compound **12-08**
addition of organometallics to nitriles **16-33**
aldehydes + amines or ammonia **16-13**
alkynes + amines **15-08**
dehydrogenation of amines **19-05**
from imines + RMgX **10-69**
ketones + amines or ammonia **16-13**
oxidation of primary amines **19-21**
rearrangement of cyclopropyl **18-31**
reductive alkylation of aldehydes or ketones **16-17**
thermal rearrangement of alkyl azides **18-14**
via Bischler–Napieralski reaction **10-13**

IMINO ESTERS
haloimines + aroxides **18-42**

ISOCYANATES
amides + hypohalites **18-13**
amines + CO **12-53**
base induced rearrangement of hydroxamic acids **18-15**
carboxylic acids + HN_3 **18-16**

Curtius rearrangement **18-14**
from acyl halides **10-44**
from alkyl halides **10-44**
from nitrile oxides **18-44**
Hofmann rearrangement **18-13**
phosgene + amines **16-72**
the Schmidt reaction **18-16**
thermal rearrangement of acyl azides **18-14**

ISONITRILES (ISOCYANIDES)
alkyl halides + cyanide **10-75**
amines + trihalides **10-40**
dehydration of formamides **17-31**
from oxetanes **10-40**

ISOTHIOCYANATES
from acyl halides **10-44**
from alkyl halides **10-44**

ISOTHIOURONIUM SALTS
from alkyl halides **10-25**

KETALS
ketals + RM **10-64**
ketones + alcohols **16-05**
reductive cleavage of ortho esters **19-56**

KETENES
base-induced elimination of acyl halides **17-14**
dehydration of carboxylic acids **17-01**
elimination of haloacyl halides **17-23**

KETENIMINES
by the Wittig reaction **16-44**
dehydration of amides **17-01**

KETO-ALDEHYDES
ketals + formamides **12-16**

KETO-ALKYNES
elimination of epoxy-hydrazones **17-27**

KETO-AMIDES
alkenes + acyloxy salts + nitriles **15-56**
amino acids + anhydrides **12-42**

KETO-CARBOXYLIC ACIDS
active H compounds + CO_2 or CS_2 **16-42**
carboxylic acids + esters **16-87**

KETO-ESTERS
acyl halides + active H compounds **16-84**
aldehydes + diazoketones **12-18**
alkenes + acyloxy salts **15-56**
alkylation reactions **10-67**
Claisen condensation **16-85**
haloesters + esters **16-28**
haloesters + nitriles **16-28**

KETO-ESTERS, CONJUGATED
by the Knoevenagel reaction **16-38**

KETO-NITRILES
acyl halides + active H compounds **16-84**
by the Thorpe reaction **16-50**
condensation of nitriles **16-50**
esters + nitriles **16-86**
from ketones **12-19**

KETO-SULFIDES
Ketones + disulfides **12-14**

KETO-SULFONES
acyl halides + active H compounds **16-84**

KETO-SULFONIC ACIDS
ketones + sulfur trioxide **12-14**

KETONES
acyl halides + aromatic compounds **11-17**
acyl halides + organometallic compounds **16-81**
addition of organometallics to nitriles **16-33**
aldehydes + alkenes **15-34**
aldehydes + boranes **12-18**
aldehydes + heterocycles **14-19**
aldehydes + transition metal complexes **12-18**
alkenes + aldehydes **15-34**
alkenes + alkenes + CO **15-36**
alkenes + ketones **15-33**
alkyl halides + organoiron compounds **10-76**

alkylation of enamines **10-69**
alkylation of hydrazones **10-68**
alkylation of ketones **10-68**
alkylation reactions **10-67**
amines + HONO **12-50**
and keto–enol tautomerism **12-03**
aromatic compounds + acyl halides **11-17**
aromatic compounds + aldehydes **14-19**
aromatic compounds + anhydrides **11-17**
aromatic compounds + carboxylic acids **11-17**
aromatic compounds + nitriles **11-24**
aryl diazonium salts + oximes **14-23**
arylation of ketones **13-14**
arylation **13-14**
by cleavage of alkoxides **12-41**
by decarboxylation **12-40**
by Michael addition **15-24**
carbonyl transposition **12-14**
carbonylation of metal alkyls **13-15**
carboxylic acids + organolithium reagents **16-29**
cleavage of diketones **12-43**
conjugate addition of alkyl halides **15-28**
conjugate addition of allylic slanes **15-26**
conjugate addition of boranes **15-27**
conjugate addition of boranes **15-27**
conjugate addition of organometallics **15-25**
cyanoboranes + anhydrides **18-23**
decarboxylative alkylation **14-31**
decarboxylative coupling of 2 acids **16-90**
diazo ketones + boranes **10-73**
elimination (1,3) of halo-amines **17-25**
elimination (1,3) of diols **17-25**
elimination (1,3) of halohydrins **17-25**
Friedel–Crafts acylation **11-17**
Fries rearrangement **11-27**
from aldehydes **12-18**
from alkyl halides **10-76**
from anhydrides **11-17**
from aryl halides **13-15**
from boranes **10-73**
from cyanohydrins **10-68**
from diazoketones **10-73**
from dihaloalkenes **10-02**
from dihydrooxazines **10-72**
from dithianes **10-71**
from dithioketals **10-06**
from dithioketals **16-11**
from enamines **10-69**
from halo-ketones **10-73**
from imines **10-69**
from ketones **10-68**
from keto-sulfoxides **10-67**
from nitriles **11-24**
from organometallics **12-33**
haloketones + boranes **10-73**
homologation of ketones **18-09**
hydration of alkynes **15-04**
hydration of allenes **15-04**
hydrolysis of C=N compounds **16-02**
hydrolysis of dithioketals **10-06**
hydrolysis of dithioketals **10-71**
hydrolysis of enol ethers **10-06**
hydrolysis of furans **10-06**
hydrolysis of *gem*-dihalides **10-02**
hydrolysis of imines **16-33**
hydrolysis of ketals **10-05**
hydrolysis of nitro compounds **16-03**
hydrolysis of orthoesters **10-06**
hydrolysis of vinyl ethers **10-06**
hydrolysis of vinyl halides **10-01**
imines + RM **10-69**
insertion of diazo ketones **12-21**
ketenes + alkenes **15-63**
keto esters + alkyl halides **10-67**
ketones + diazomethane **18-09**
Nef reaction **16-03**
oxidation alkenes **19-25**
oxidation of alcohols **19-03**
oxidation of dicarboxylic acids **19-13**
oxidation of methylene **19-17**
oxidation of nitro compounds **19-21**
oxidation of primary amines **19-21**
oxidation of vinyl boranes **18-26**
oxidative cleavage of alkenes **19-10**
oxidative cleavage of diols **19-07**
oxidative cleavage of enamines **19-10**
ozonolysis of alkenes **19-09**
pinacol rearrangement **18-02**
pyrolysis of hydroxy-alkenes **17-32**
radical addition to conjugated ketones **15-28**
rearrangement of aryl esters **11-27**
rearrangement of diols **18-02**

rearrangement of epoxides **18-02**
rearrangement of ketones **18-04**
rearrangement of peroxides **18-20**
ring expansion of amino alcohols **18-03**
ring expansion of halohydrins **18-03**
Sakurai reaction **15-26**
silyl enol ethers + alkyl halides **10-68**
tautomerization of enols **12-03**
transesterification of vinyl esters **16-64**
transition metal carbonyls + RM (M = metal) **12-33**
Wacker process **19-25**
Weinreb amides + organometallic compounds **16-82**

KETONES, CONJUGATED
aldol condensation **16-34**
alkenes + acyl halides **12-16**
carbonylation of vinyl-M (M = metal) **12-33**
coupling of dienones **15-20**
oxidation of methylene **19-17**
Pauson–Khand reaction **15-36**

LACTAMS
alkyl halides from amides **10-41**
and Michael addition **15-31**
by Beckmann rearrangement **18-17**
cyclic ketones + HN_3 **18-16**
cyclic ketones + silyl azides **18-16**
from amino carboxylic acids **16-74**
from haloamides **10-41**
lactams + amines **16-76**
lactones + ammonia or amines **16-75**
N-arylation **10-41**
N-vinylation **10-41**
oxidation of methylene in amines **19-17**
rearrangement of oximes **18-17**
reduction of imides **19-64**
Schmidt reaction **18-16**

LACTAMS, β
diazo-[2 + 2]-cycloaddition **15-63**
enamines + ketenimines **16-96**
ketenes + C=N compounds **16-96**
ketones + C=N compounds **16-96**
rearrangement of hydroxy-haloamines **18-18**

LACTONES
